Mr. Gibson accordingly advocates the formation of a committee, armed not merely with the knowledge already existing in the P E P report and the report of the Barlow Commission, but also with the widest powers possible in war-time. No vested interest should be allowed to withhold from it information necessary for the preparation of a long-term plan. The keynote of this committee and of the local town-planning committees linked with it should be decentralization and regeneration—an attempt to reverse the present tendency and encourage a network of clean, healthy towns.

This suggestion would appear to have been adopted in essence by Lord Reith, who, in the House of Lords on February 26, stated that he was inviting a dozen or twenty individuals who had special experience to assist him, and to be associated from the beginning in a consultative capacity with the central planning and co-ordination of post-War physical reconstruction. Lord Reith also proposes to use the resources of other departments and to ask for the collaboration of professional and technical associations. An offer from the council of the Royal Institute of British Architects has already been welcomed by him. Lord Reith also stated that he has been authorized to proceed on the assumption that the principle of planning would be accepted as national policy, and that some central planning authority would be required which would proceed on a positive policy for agricultural and industrial development and transport, and that some services would require treatment on a national basis, some regionally, and some locally.

Besides this question of national planning and all that is involved in the use of the land, and the subordination, for the good of the community, of private interests to public ones, there is an immense field for technical development. Too seldom does the architect or builder remember that it is his duty to-day to make his design—whether house or public building or factory—suit the needs of the people, and achieve beauty with the use of all the technical advances at his disposal. Mr. Gibson was able to point to the way in which developments and new ideas are being incorporated in houses now being constructed in Coventry, and he urged that to build for permanence is a mistake, limiting or hampering the satisfaction of the needs of to-morrow.

These are revolutionary ideas to many, but it is only by recognizing their force that we can hope to utilize to the full the new knowledge and materials which science is placing at the disposal of the building industry to satisfy the cultural and æsthetic needs of the community, as well as its material needs. They may involve departure from traditional practice and organization, and Mr. Gibson himself advocates the establishment now of a committee of architects, to face these problems, with representatives from aircraft works both on the design and organization sides, and of the Building Research Station, so that the new forms of construction may be ready when the call comes and the transition of factories from war-work to the production of houses, using the light, efficient and beautiful materials which are employed with such efficiency and economy in aircraft, may be facilitated. Moreover, the work of the architect, the planner and the engineer must go hand-in-hand, with a clear definition of the spheres in which each can best serve the community. For the building industry, Mr. Gibson visualizes a new type of educational centre—a combination of technical school, architectural school and town-planning department, in which students would learn to handle and work on materials in the early years and would be sifted out in accordance with their talents and ability, the most gifted becoming planners of the future environment.

INDEX LONDINENSIS

Index Londinensis to Illustrations of Flowering Plants, Ferns and Fern Allies

Supplement for the Years 1921–35. Prepared under the auspices of the Royal Horticultural Society of London at the Royal Botanic Gardens, Kew, by W. C. Worsdell, under the direction of Sir Arthur W Hill. Part 1: A—H. Pp. vii+497. Part 2: I—Z. Pp. iv+515. (Oxford: Clarendon Press; London: Oxford University Press, 1941.) 2 vols., £10 10*s*. 0*d*. net.

The appearance of this supplement to "Index Londinensis" is an event of more than ordinary interest to all botanists and scientific horticulturists. Its production in time of war in the same style and with the same high standard of excellence which marked the original work will be regarded as a fine achievement.

The first and for many years the only work of its kind was Pritzel's "Index Iconum Botanicarum", published in 1855. This provided a convenient alphabetical register of illustrations of flowering plants and ferns selected from botanical literature from about the time of Linnæus onwards. During the latter part of the nineteenth century, however, the rapid progress of botanical science and the increasing use of illustrations in botanical writings made it desirable that Pritzel's "Index" should be revised and brought up to date. This was a task of no small magnitude, but thanks to the enterprise and support of the Royal Horticultural Society the work was successfully accomplished, and the six volumes of "Index Londinensis" were issued at intervals between 1929 and 1931, under the editorship of the late Dr. O. Stapf of the Kew Herbarium. The work was an emended and enlarged edition of Pritzel's original register, which now possesses only historic interest, and included all references to figures of flowering plants and ferns down to the end of the year 1920.

Although the six volumes of "Index Londinensis" were estimated to contain nearly five hundred thousand entries, they were no sooner published than work on a supplement was commenced. The two volumes now before us are a handsome addition to the main work and are sure of a warm welcome from all who know the value of the original. The supplement has been prepared under the supervision of the Director of the Royal Botanic Gardens, Kew, with the assistance of Mr. W. C. Worsdell as sub-editor, while the onerous task of compilation has been undertaken by Miss R. L. Burford. Not only does the supplement provide the student with a great array of references to botanical drawings taken from periodicals and independent works published during the years 1921–35, but it directs attention also to an extensive and widely scattered literature much of which might easily be overlooked.

In the preparation of the supplement, the general plan and scope of the main work have been closely followed. The text is clearly printed in three columns to the page, with generic names of plants as page-headings. In each column, plant names are printed in clarendon type, and under each genus the names of species are arranged in alphabetical order, while the references under species-names are placed in chronological sequence. Since the period covered by the supplement is the comparatively short one of fifteen years, it is not altogether surprising that only one or two references to figures appear under many of the names of species. Yet the size of the two volumes (more than one thousand pages) is to some extent a measure of the amount of taxonomic and morphological work which botanists have accomplished on flowering plants and ferns during the years 1921–35. Nor have all references been given, for the supplement, unlike the main work, "contains under most of the species-headings, only a selection of references, thus keeping its size within certain limits". On the average, about seventy names of species appear on each page, so that references are given to some seventy thousand species altogether. The consequences of intensive study of certain groups are plainly seen throughout both volumes. Six or more pages are taken up, for example, with the references to such genera as Bulbophyllum, Carex, Eucalyptus, Sedum, Rhododendron and Quercus.

The system of cross-references will again be welcomed. It is difficult even for the trained botanist to keep abreast of all the changes in plant nomenclature, and we can well believe that even the specialist in grasses, when he turns to the genus Poa, will be grateful for being told to see also Atropis, Festuca, Glyceria, Sclerochloa and Sesleria, or the pteridologist for the note under Aspidium to consult also Dictyocline, Dryomenis, Dryopteris, Lastrea, Nephrodium and Polystichum.

We would have been grateful for the inclusion in the supplement of an explanation of the symbols which are employed to indicate the nature of any given illustration, whether in colour, etc. Only in volume I of the main work are the symbols explained. Again, many of the references are to photographic illustrations, but there does not appear to be any indication of this under the several entries. The omission, however, is a small one, and we have nothing but praise for those who have in any way contributed to the preparation of the supplement, and a special word of gratitude to the Royal Horticultural Society for having shouldered the cost of its production.

From the preface we learn that the supplement concludes the "Index Londinensis", and although no further supplements are to be published, references to new illustrations will be included in future supplements of the "Index Kewensis". The whole publication now brought to successful completion is an invaluable and indispensable work of reference, and it should find a place in every botanical library.

J. R. MATTHEWS.

THEORY OF ELECTRODYNAMICS

Electrodynamics

By Prof. Leigh Page and Prof. Norman Ilsley Adams, Jr. Pp. xii + 506. (New York: D. Van Nostrand Co., Inc., 1940). 6.50 dollars.

ELECTRICITY and magnetism, like mechanics, being a subject of great importance and interest, both practical and theoretical, is widely taught. Even more than mechanics it offers scope for a variety of treatment in teaching, and because many teachers have felt that their particular methods are of general interest, the number of text-books and treatises on electricity and magnetism is considerable and ever increasing. Apart from the distinctive views of different teachers, there is need for a variety of treatments, because of the varied needs, outlook and equipment of different types of student. In time a consensus of opinion on the best methods appropriate to each type of student may be arrived at; the good features of groups of good books of similar type and scope may then be combined, by some future

Euclids of the subject, in single volumes replacing the present books in each group. But the time for this has certainly not yet come; there remain great differences of opinion as to some parts of the theory, even on apparently elementary points; still further distant is the time when a best mode of transition from the classical to the quantum theory will be generally agreed upon. Many new essays of exposition must be made before the presentation of the higher parts of the subject attains relative stability and uniformity.

In a recent issue of NATURE (146, 446; 1940) a treatise "Static and Dynamic Electricity" by Prof. W. R. Smythe was enthusiastically welcomed by Prof. G. Temple, who from his own experience in using it as a research tool had found that it successfully achieved this its avowed object. An advanced treatise of a very different type, by Profs. Page and Adams, now under notice, lays special stress on the *theoretical* aspects of electrodynamics, and almost entirely omits electrostatics and magnetostatics, on the ground that they are already excellently treated elsewhere. This naturally limits the appeal of their book, but it is to be warmly welcomed as an original and carefully considered exposition of the subject from a logical point of view. Its special feature is that the relativistic attitude is adopted from the outset, and Maxwell's field equations are deduced on the basis of the emission theory. The authors have, however, made no attempt to include quantum electrodynamics or any of the special results of the quantum theory.

The book uses vector and tensor methods throughout, and the first chapter (77 pp.) gives an excellent condensed exposition of the main vector and tensor theory needed later. Chapter II (51 pp.) deals with the principle of relativity, first for a one-dimensional and afterwards for a three-dimensional system, leading to the Lorentz space-time transformation; the treatment in this chapter is a modified form of that given by Prof. E. A. Milne in his book "Relativity, Gravitation and World Structure."

The discussion of the electromagnetic field begins (Chapter III) with an extension of Faraday's conception of lines or tubes of force. Every element of the charge is regarded as the focus of a bundle of tubes, interpenetrating, but not influencing the tubes from other charges: the number of tubes for any element of charge is taken as identical with the number of units of electricity in the charge, "and we are led automatically to the Heaviside-Lorentz units". Each element of charge is regarded also "as a group of emittors each of which shoots forth a stream of moving-elements with the velocity of light, in much the same way as a machine gun fires a stream of bullets. The locus, at any instant, of the moving-elements which have been projected from a given emittor, constitutes a line of force. Now we shall adopt two assumptions suggested by symmetry. First we assume that, relative to the inertial system in which the element of charge is momentarily in rest, the emittors are distributed uniformly at angle, and second, that the emittors have no rotation relative to this inertial system". The electric intensity **E** at a point P is defined by the property that its component in any direction **n** is equal to the number of tubes of force (from the elementary fields of all the charges) that cross an element of area through P, normal to **n**, per unit area.

The relativity transformation of **E**, thus defined, for a single elementary field, from one inertial system to another, introduces the vector product $(1/c)\, \mathbf{c} \wedge \mathbf{E}$, where **c** is the velocity of the moving-element at P; "it is convenient to represent" this vector "by a single symbol and to attach a name to it": the chosen symbol and name are **H**, *the magnetic intensity* of the elementary electric field. The relativity transformation of **H** is then found. The resultant **H** at a point, due to several elementary electric fields, is defined as in the case of **E**. It is then possible to infer the field of a moving accelerated point charge, to express it in terms of retarded potentials, and to show that these, with **E** and **H**, satisfy equations "identical with those formulated by Maxwell to describe in analytical form the experimental discoveries of Coulomb, Ampere and Faraday", so that "we can now identify unambiguously the vector **H** with the magnetic force as measured experimentally". Since the equations are linear, they are true also for the field of any number of moving elementary charges. In the next chapter (IV) the analysis is extended to a point charge which has also electric and magnetic moments (the "spinning electron").

The later chapters, which depart less than Chapters III and IV from the usual treatment, discuss material media, energy, stress, momentum and wave motion, radiation and radiating systems, the electromagnetic theory of light, four-dimensional vector analysis and general dynamical methods.

In elementary teaching it seems best to develop the subject in close touch with the few great key experiments; at a later stage some students will wish to see the theory based on a more axiomatic foundation, making contact with experiment only after a series of arguments. This is the task essayed by the authors of this book, and there will doubtless be many teachers who will carefully consider and experimentally use the method of presentation adopted by Profs. Page and Adams.

S. CHAPMAN.

THE ROYAL BOTANIC GARDENS, KEW

CENTENARY AS A GOVERNMENT INSTITUTION

HISTORY OF THE GARDENS

By PROF. F. O. BOWER, F.R.S.

THE origin of the Royal Botanic Gardens at Kew, like that of many other public institutions in Great Britain, may be traced to personal initiative. Though the original site was small, it has been greatly expanded under public guidance and support during the century completed on April 1, 1941. In the eighteenth century a Royal Residence, together with certain houses for accommodation of the Court, clustered about the village of Kew, while a level expanse of alluvial soil on the south bank of the Thames offered a favourable opportunity for horticulture in the relatively pure country air. The methods suggested by Bacon in his essay on gardens were doubtless practised there, and in some degree realized by the ladies of the Court, and in particular by a royal princess. For close to the village lay Kew House and grounds, which were held on lease from 1730 by Frederick, Prince of Wales. It was there that his wife, the Princess Augusta of Saxe-Gotha founded a private botanic garden upon some eleven acres of the enclosed grounds. This first scientific garden of Kew is now merged in the north-easternmost part of the present Royal Gardens. It lies close to the main entrance from Kew Green, and its site is still to-day the intensive centre of the Kew establishment.

The Princess was aided in the foundation and management of that first botanic garden at Kew by the Earl of Bute; also by the architect Sir William Chambers, who designed plant-houses, temples, the Pagoda, and other features of the grounds, after the fashion of the time; some of these are still standing. She was further helped by William Aiton, the author of "Hortus Kewensis", who took charge of the scientific development of the garden. On the death of Princess Augusta in 1772 the property passed into the hands of her son, George III, and it was merged into the adjoining domain of Richmond Lodge. Thus the two properties became united as the oldest part of what is now known as Kew Gardens.

The botanical interest of the garden survived these changes, though its activity slackened. Fortunately, the place of the Earl of Bute as scientific director was taken by Sir Joseph Banks. The date of this change must have coincided nearly with his active participation in organizing Captain Cook's expedition which resulted in the first scientific exploration of Australia and New Zealand. Through him Kew was thus linked closely with botanical enterprise in distant lands. Moreover, its scope was further extended by the dispatch from Kew itself of a succession of collectors. The first of these started in 1772 for the Cape of Good Hope. The collections in the garden were thus enriched from time to time by plants newly discovered or introduced, and the prestige of the garden during a difficult period of transition was for a time upheld.

In 1820 both George III and Sir Joseph Banks died. Thereafter the garden suffered a period of neglect. For twenty years its fate hung in suspense; some even advocated its abolition as a scientific centre. But gradually public opinion began to assert itself. A committee of inquiry was appointed in 1838, with Dr. J. Lindley and Sir Joseph Paxton as its leading members. Their report sketched the ideal of an Imperial Botanical Service of which Kew should be the centre, with establishments elsewhere acting in concert with it. Towards the realization of such an ideal the subsequent development of Kew has ever since aspired, and the high degree of its success is now generally admitted.

In 1840 W. T. Aiton retired. The control of the garden was then transferred from the Lord Steward to the Commissioners of Woods and Forests. It was essential in the first place to secure as director the most able and enterprising botanist available. He was found in the person of Sir William Hooker, regius professor of botany in the University of Glasgow. As a prolific writer on descriptive botany, and as a strenuous director of the growing garden in Glasgow, he was already known throughout the scientific world. These qualifications, together with something of the *grand seigneur* in his personal manner, clearly indicated him as the right man. He took up his duties on April 1, 1841, and this date may be held as marking the birth of the modern Kew. On his arrival, Sir William Hooker found the garden to consist of about eleven acres; but it was in a neglected state; moreover, it was without any residence for the director. There was no museum nor any herbarium or library except his own. All the prime requisites for the scientific conduct of a botanic garden had to be improvised. Nevertheless, in 1841 the garden, hitherto private, was thrown open to the public, and it was visited by more than nine thousand persons in that year.

Thus established as a public institution, Kew Gardens grew like a crystal in a supersaturated solution. What had been lacking was initiative. In 1842 four acres were added, near to the present main gate. and in 1844 the area was increased by forty-one acres taken from the Pleasure Grounds. Two years later fourteen more acres were added. Then the Pleasure Grounds were placed under Sir William's charge, and finally added to the garden, as well as the enclosure surrounding the Queen's Cottage. The result has been that the whole domain of Kew now extends to about 318 acres, all within a ring-fence of simple outline. These extensions of area have been accompanied by the provision of buildings, such as plant-houses, museums, Herbarium and Library. From time to time houses belonging to the Crown, and mostly facing upon Kew Green, have been absorbed for special botanical purposes, or as official residences for the senior members of the staff. Of the plant-houses the greatest is the 1844–48 Palm House built in 1845. The Temperate House was commenced in 1860, but not completed until 1899. There have also been added houses for tropical ferns; a water-lily house, built originally for the *Victoria regia* in 1852, and the so-called T-range where the Victoria water-lily is raised annually from seed. These are examples of the widespread facilities for cultivation under glass. The scientific interest in the living collections really centres in the propagating pits; but these cannot be opened to the public.

The systematic study of plants, as conducted at Kew from dried specimens, concentrates naturally upon the Herbarium, and the various museums. It will be seen in detail later, from the article written by the Director, how Sir William Hooker on his arrival in 1841 brought with him the rich collections which he had accumulated in his private house in Glasgow. But several years elapsed before these found suitable accommodation in the garden at Kew. Eventually they formed the foundations of the present museums, and of the great Herbarium. Each of these departments has been vastly increased by accession of material throughout the century now completed. The Herbarium itself is the focus of the systematic work done at Kew. It has been the source of many classical publications, such as the "Genera Plantarum" of Bentham and Hooker, the "Index Kewensis", the "Flora of British India", and those of the several Dominions and Colonies of the British Empire. Hence issue such serials as the "Icones Plantarum" and the *Kew Bulletin.* Here also much other literary work both of British and foreign origin is being constantly pursued. The building which houses this great "Hortus Siccus" and its magnificent Library originated from a private dwelling-house facing upon Kew Green. It stands on the right as one enters the Main Gate of the Gardens. But the original central block is almost lost among the large additional wings, which have become necessary to accommodate the ever-growing collections of dried plants, and the rich library so necessary for their study.

As in the animal body the co-ordinating brain is hidden away and protected in the skull, so in Kew the Director's office is protected from the public eye. In a quiet backwater, shut off from the constant stream of visitors, there is an inconspicuous brick building, not beautiful or antique, towards which the imperial interests in botany converge. Here is the centre of administration of the Gardens with its numerous staff, while from it radiates information and advice not only for those at home, but also to the Dominions and Colonies—and to foreign lands as well; for there is an international freemasonry in science, which even war does not wholly paralyse.

Teaching, as such, is not undertaken in the Royal Gardens, though demonstration of living plants is encouraged there, while instruction deemed suitable is given to the student gardeners in training. But research has always been actively aided there, whether it be pursued by the staff or by accredited members of the public. Naturally, systematic work on dried plants is readily enough carried out in the Herbarium. But morphological or physiological research requires such accommodation as a specially designed laboratory alone could afford. The need for this became urgent as the revival of the study of those branches of the science took effect in the seventies of the last century. Through the munificence of Mr. J. Phillips Jodrell a research laboratory was built and presented by him to the Gardens in 1875. It is a small block of red brick and stone, placed in the north-eastern corner of the Gardens, close to the office-yard and propagating pits. Tyndall and Burdon Sanderson were among the earliest to use so convenient a place for research on living plants, and they have been followed by many others. In particular, some of the initial experiments leading towards the manufacture of artificial silk were carried out there—also certain remarkable experiments on the control of gaseous interchange in sub-aerial plants. Sustained inquiries on fossil plants of the Coal Period were also conducted there by Williamson and Scott, the latter having acted for many years as honorary keeper of the Laboratory. These are merely examples of work which has been done in the Jodrell Laboratory by the long sequence of botanists who have used it. Their results have proved the value of this late adjunct to the Royal Gardens.

Nothing has marked the recent decades of botanical research more clearly than the advance of preventive practice against plant diseases, and especially those of fungal origin. Such work under Government subvention has been centred in the Imperial Bureau of Mycology. This is at present located at Kew, in a building in close juxtaposition with the Herbarium, though the autonomy of the Bureau is still preserved. Nevertheless, in spirit and in purpose it may be held as part of the establishment at Kew, helping to round off its activities which at the first were relatively simple, but have naturally expanded as the century of its existence passed, and the science itself advanced.

This brief sketch of the origin and evolution of the establishment known as the Royal Botanic Gardens at Kew during the first century of its existence will commend it as an institution worthy of the highest esteem by the public which it serves. For its purpose is not merely as a place of joyful recreation for holiday crowds, but also as one of the most striking and least costly exponents of scientific enterprise within the British Empire.

KEW IN RECENT YEARS

By Sir Arthur Hill, K.C.M.G., F.R.S.

The foundations so well and truly laid by Sir William Hooker to make the Royal Gardens at Kew a botanic garden worthy of the nation, as a place of education, healthful recreation and research, have nobly stood the test of time, and now after a hundred years, though the War, alas, has sadly curtailed normal activities, the Royal Botanic Gardens are carrying on the various lines of wo[illegible] they were envisaged by Sir Willi[illegible] Other import[illegible] Sir Joseph Hooker and thei[illegible]cal, metallurgical and [illegible] them, indeed, can be traced back to the great days of Sir Joseph Banks and George III.

The general plan and functions of the Gardens have altered only in detail; additions have been made and the general amenities and beauty of the Gardens have been improved, despite the increase of London smoke and fog and its deleterious effect on vegetation and especially on coniferous trees. So much have these been affected that it has been necessary to establish a National Pinetum at Bedgebury in Kent, so that the conifers may develop to the best advantage. This joint effort of Kew and the Forestry Commission comes under the direction of Kew.

Other improvements in recent years include the addition of Cambridge Cottage and its garden, with the formation of the Museum for the display of British timbers and the products derived from them, photographs and specimens of the trees and exhibits of the fungus and other diseases to which trees are liable. By the side of the Museum medicinal plants have been planted in a series of beds around the sundial made and presented by Sir Charles V. Boys, arranged on the plan of the botanical garden at Pisa.

The Rock Garden has been considerably enlarged at its northern end by the formation of an 'island' of Sussex sandstone almost surrounded by a stream, and two new entrances have been constructed at the northern end. The water garden, in front of Museum II, based on the design of the sunk garden at Hampton Court, with raised tanks which enable the plants to be studied with ease, has proved a considerable attraction and a very desirable addition to the Gardens. The Alpine House, the original one being the first of its kind to be erected, was entirely rebuilt and enlarged in 1938.

From the general educational point of view attention should be directed to the planting out of the tree ferns in the Tropical Fern House, and the arrangement of the epiphytic ferns and other epiphytes on tree trunks, etc., as they grow in their native forests. The stag's-horn ferns (Platycerium) in the centre of the House, growing on tree trunks, make a particularly fine and realistic display. Attention may also be directed to the houses devoted to the fine collection of pitcher plants, insectivorous plants and Cape Pelargoniums, the two latter having been constructed when the Economic Houses were rebuilt and much enlarged in 1930.

The gift of Mrs. Sherman Hoyt of the new Cactus House, with its painted background of the Mohave Desert, California, has enabled the public to appreciate the way these plants grow in their natural habitat—the foreground being built up with blocks of old red sandstone so closely harmonizing

MINERAL RESOURCES OF CONTINENTAL EUROPE

BY DR. W. J. ARKELL

WHAT exactly are the mineral resources of the German Old Reich, and what does she stand to gain from the resources of her allies and her conquests? What attractions are offered by the remaining neutral countries of Europe? What minerals deficient in Europe can be supplied by the U.S.S.R.? There appears to be no up-to-date account of this important subject in the English language.

In the following synopsis Continental Europe is understood to mean Europe less the British Isles, Spitsbergen, Turkey and Russia.

Only minerals of strategic importance are dealt with. They may be grouped as follows:

(1) Fuels: oil and coal.

(2) Major metals: iron, copper, lead, zinc, tin.

(3) Steel alloy metals: manganese, chromium, nickel, cobalt, tungsten, molybdenum, vanadium, zirconium, titanium.

(4) Other metals: aluminium, magnesium, mercury, antimony, arsenic, uranium, platinum.

(5) Fertilizers: phosphates and potash; also [illegible]rites, needed for the manufacture of super-[illegible]

[illegible]ant non-metals, used in the [illegible] industries (mica, [illegible]

of lignite, which is 36 per cent of the world's total production, although Europe has only 2 per cent of the world's reserves.

Iron: Germany possessed 17 per cent of the European reserves of metallic iron, but her ores are mainly low-grade and therefore extravagant to work. For her immense steel industry she was mainly dependent on imports.

Copper. In the Mansfeld stratified deposit Germany possesses the most important copper occurrence in Central Europe, and with more than 20 per cent she had the highest copper production of any European country after Yugoslavia. But the total European production being only 6·3 per cent of the world production and the reserves (including huge deposits in Spain) only 10 per cent of world reserves, the total amount of copper is inadequate for the highly developed electrical industry. It is being increased by developing newly discovered low-grade ores in Silesia and eastern Hessen. The latter field is said to be perhaps as important as Mansfeld itself.

Zinc and Lead. In her share of Upper Silesia, Germany possessed about 15 per cent of the richest zinc and lead deposits in Europe, the rest belonging to Poland. These and numerous other deposits in different parts of the country gave [illegible]erves of about 7·4 million tons of [illegible] million tons of recover-[illegible] and 29 per cent she [illegible] with the rocks of the painted background that the two pass almost imperceptibly one into the other.

The adjoining house, devoted to the succulent vegetation of South Africa, planted among triassic rocks and quartzite which exactly match the Karroo formation, was a gift to Kew in commemoration of the Silver Jubilee of King George V, and is of great educational value. The button-like Mesembryanthemums growing, as in Nature, among conglomerate rocks, are only distinguishable with difficulty from the pebbles in the conglomerate.

Among the trees and shrubs many additions have been made, thanks to recent explorations in China, Thibet and Chile, which not only have fully utilized all the available ground in the Gardens, but have also necessitated the building of an annexe to the Temperate House for the tender Rhododendrons.

Much has also been done to improve the pits and other houses in the private parts of the Gardens where the plants are propagated and grown for distribution to the Colonies and for display. A house next to the Orchid Houses has also been set aside for the display of plants of particular interest and for the exhibition of the history of well-known plants, such as Primulas, 'Geraniums' and plants of special biological interest, while during the summer certain beds are devoted to the cultivation of annual plants according to their countries of origin, so that the public may learn whence some of the plants now commonly grown in gardens are derived.

Turning to the more scientific side of the Gardens' activities—exhibits of interest are arranged from time to time in th
illustrate matters of part
while in the Herb

be mentioned "The Flora of West Tropical Africa", 2 vols. with the "Useful Plants of West Tropical Africa" as an appendix volume of 612 pages; "The Cultivated Crop Plants of the British Empire"; the completion of the "Flora Capensis"; and the continuation of the "Flora of Tropical Africa".

Among the more recent plant introductions to the Colonies, that of tung oil (Aleurites) should prove of importance. Kew is also assisting in the effort to combat the Panama disease of bananas by collecting bananas from various sources and growing them in a specially built Quarantine House before dispatching offsets free from diseases to the Imperial College of Tropical Agriculture, Trinidad, for cross-breeding experiments. Similar assistance is being given to Trinidad, Nigeria and the Gold Coast in connexion with the witch-broom and other diseases of cacao, and to the Researc
Institute, Amani, in connexion with mosaic diseas
of Cassava.

The Royal Botanic Gardens, Kew, theref
after a hundred years are still engaged in fur
ing every kind of botanical enterprise that ma
of assistance to the Empire, and in training a
of student gardeners to carry out the scienc
practice of horticulture both at home and ov
besides affording pleasure to thousands
visitors.

The following passage from the Book "
asticus" might well be applied to Kew, when i
remembered that Sir William Hooker, when
became director on April 1, 1841, had a garden
only eleven acres without any
or laboratory buildings

Nickel. Although recent production of nickel ore in Germany has been very small (268 tons was the greatest amount in any year from 1935 to 1938), there are a number of deposits, and production can be increased about four-hundred-fold in times of stress. The output reached 102,000 tons in 1917. This represents about 2,050 tons of nickel, or 73 per cent of the total maximum annual European production for the years 1935–37, and 30 per cent of Germany's imports of nickel in the normal peace-time year 1936.

Molybdenum. About 40–50 tons of molybdenum a year can be produced as a by-product from the Mansfeld copper ores, but this is not 8 per cent of the European production, which in turn is only about 4 per cent of world production.

Vanadium. Germany's normal consumption of about 250 tons of vanadium is capable of being met by concentration of small traces which occur in the iron ores from Baden, Lorraine and Sweden, smelted in Germany.

Tungsten, Cobalt and Titanium are virtually absent.

Aluminium. Production of aluminium from Germany's negligible deposits of bauxite, if extended to the maximum, could scarcely amount to 2 per cent of her imports in recent years. On the other hand, the Germans have brought to a high state of efficiency processes for the production of aluminium from clays, kaolins and low-grade ores.

Magnesium. In Silesia there are small but pure deposits of magnesite, and the carnallite of the Stassfurt salt deposits yields 5·5 per cent of magnesium and has been extensively used as a raw material. Statistics are not available.

Mercury. Recent intensive exploitation of home supplies of cinnabar are believed to produce 200–300 tons of mercury a year, or about 30 per cent of the recent average German consumption. (This would represent about 6 per cent of the total European production and about 5 per cent of world production.)

Antimony. Germany has produced as much as 700 tons of metallic antimony in a year, which is equal to about 20 per cent of her consumption in recent years.

Arsenic. There are extensive deposits in Silesia, and as much as 4,600 tons of white arsenic have been produced in a year (1930), and as much as 2,800 tons have been exported recently in a year (1938).

Phosphates. Like many countries, Germany has various low-grade phosphatic rocks which can be drawn upon in time of war, but are scarcely worth working in peace-time. Also she has enormous reserves of phosphatic iron ores which, when smelted by the Thomas process, yield good basic slag. But of true high-grade phosphate deposits she has scarcely any.

Pyrites. Germany has twice as much pyrites as any other European country except Spain. The reserves amount to about 100 million tons, or 13 per cent of the known world reserves. In 1918 the production reached nearly 1 million tons a year, and it should be possible to exceed that now.

Sulphur. Nearly a quarter of a million tons of sulphur a year can be produced as a by-product of coal, coke and barytes industries, and during lead, zinc and copper mining. The actual amount produced hitherto in a year is probably more like half this figure.

Potash. Central Germany contains 80 per cent of Europe's deposits of potash, which are 96 per cent of the world's total reserves (less uncertain deposits in Russia). Her production in 1937 was 73 per cent of the European production and 62 per cent of world production.

Mica, Talc and Asbestos are almost entirely lacking in Germany; *diamond* does not occur in Europe.

Graphite. Germany leads European production. The deposits are extensive and easily accessible, and the output has reached 40,300 tons in a single year (1918). This would be 56 per cent of the European production if it had been repeated in 1937, and nearly 19 per cent of the world's total in recent years, as compared with 7 per cent in the British Empire and less than 4 per cent in the United States.

Fluorspar. In this Germany has a still more commanding position—a matter of importance in view of its great value in the steel industry. Her production is more than 68 per cent of the total European production and nearly 33 per cent of the world's total (as compared with 10·7 per cent in the British Empire).

AUSTRIA

Magnesium. The outstanding gain to the Reich war machine in taking over Austria was the acquisition of the world's largest and purest deposits of magnesite for the making of magnesium for incendiary bombs, flares, and aircraft. For years Austria headed the world's production and has only recently been just outstripped by Russia.

Other metals. Minor assets are small quantities of iron, lead and antimony (more than double Germany's production of antimony has been reached).

Talc. Austria's production of 16·7 per cent of the European total is four times as great as Germany's, and satisfies a need.

Graphite. Austria's graphite deposits are second only to Germany's. The two together give Germany a commanding position with a production of more than 40,000 tons a year, or 74 per cent of the European production in 1937, and potentialities for producing more than 60,000 tons a year, as was done during the War of 1914–18 (28 per cent of the present-day world's total).

CZECHOSLOVAKIA

Lignite. The Sudetenland contains a reserve of 11½ million tons of lignites of a quality far superior to those of Germany; they represent about 12 per cent of the European reserves.

Asbestos. With 15 per cent of the European production this will be a welcome asset, since Germany and Austria possess practically none.

Graphite. The graphite deposits of Bohemia and Moravia are among the most valuable in Europe, and production exceeded 41,000 tons in 1927—equal to Germany's maximum production during the War of 1914–18. This extra acquisition gives Germany practically a monopoly of European graphite.

Uranium. Bohemia contains by far the most important uranium deposits in Europe, practically the only others being in Portugal. For many years she led the world's production.

Antimony. Czechoslovakia accounted for 30 per cent of Europe's antimony production in 1937.

POLAND

Oil. Poland produced more than half a million tons of oil a year. The Germans and Russians took over the industry in full working order. The German share represented a production of only about 150,000 tons a year, but this is capable of substantial increase, and is a clear gain to Germany. It is considered probable that the oil from the Russian part of the field will also go to Germany.

Coal. The Dombrova and Ostrawa-Karwina coalfields made Poland the third largest coal-producing country in continental Europe, with 11 per cent of the output and 28 per cent of the reserves. She also has lignite reserves larger than those of Czechoslovakia and almost entirely undeveloped.

Zinc. Polish Upper Silesia contains a continuation of the German Silesian zinc and lead ores. The output of zinc in 1937 was 15·6 per cent of the European production, and added to the German production it gives her more than 50 per cent of the total European production and about 12 per cent of world production. This is sufficient for German requirements of zinc in all circumstances.

NORWAY

The commodities that Norway can furnish are just those which Germany needed most, namely, the steel alloy metals and helpful quantities of copper and mica for the electrical industries.

Copper. The addition of the Norwegian copper production to the German represented an increase of 66 per cent, and the Norwegian output is capable of being stimulated.

Nickel. In 1917 Norway produced 78,000 tons of nickel ore, representing about 780 tons of metallic nickel, and there is no reason why this figure should not be exceeded under German direction if necessary.

Molybdenum. At present Norway is believed to be producing about 750 tons of molybdenite a year, representing about 450 tons of metallic molybdenum. It is the only important producing country in Europe.

Titanium. The Norwegian deposits of ilmenite and rutile are the largest in the world, and would suffice to furnish the world's supply of titanium for centuries. One quarter of the world's production came from Norway.

Chromium. In 1918 nearly 7,000 tons of chromite were produced. This is only a small amount, but it is valuable to Germany in the absence of other supplies.

Mica and Talc. In 1938 Norway produced more than 100 tons of sheet mica and probably at least 30,000 tons of talc. With Austria, this gives Germany 37 per cent of the European talc production and 27 per cent of the mica production.

LUXEMBURG, BELGIUM, HOLLAND, DENMARK

Iron. The only gain of real consequence accruing to Germany's mineral resources as the result of the invasion of these countries is the iron ore of Luxemburg. Although the production is only 7·2 per cent of the European total in terms of iron content, it is almost as great as Germany's own, and it is conveniently situated near the German western industrial districts and coal supplies. The amount produced in 1937 was nearly 2¼ million tons of metallic iron.

FRANCE

Iron. France has by far the largest reserves of iron in Europe, situated mainly in Lorraine. In terms of metallic iron they represent 47 per cent of the total European reserves, and the production in 1937 was 41·5 per cent of the European and 15·3 per cent of the world production.

Aluminium. The largest quantity of bauxite was also produced in France (32 per cent of European production) and the reserves are by far the largest in western Europe. In 1937 the production of bauxite in France was 18 per cent of the world's total, as compared with 10·7 per cent in the British Empire and 11·2 per cent in the United States.

Coal. France has the second largest coal production after Germany. The total production of Germany, France, Poland, Belgium and Holland represents practically 100 per cent of the European output, which is substantially greater than that of the British Empire, though the reserves of hard coal are only two-thirds as great as those of the Empire and the lignite reserves only one ninth as great.

Fertilizers. More than 70 per cent of the European production of phosphate rock came from France, and she holds about 36 per cent of the reserves. Alsace also contains the only considerable deposit of potash outside central Germany. The two together give Germany a monopoly with more than 90 per cent of the European reserves and production, and nearly 90 per cent of the whole world's potash reserve ; though Russians have recently claimed to possess a still greater reserve.

Talc. France has the largest production of talc in Europe (31 per cent), and is the third largest producer in the world, after the United States and Manchuria. In 1937 and 1938 her exports alone substantially exceeded Germany's imports.

Fluorspar. Germany has a sufficiency of this mineral in her own territory, but the French production, although little more than a third as great as the German, is still in excess of that of the whole British Empire. Germany and France together produce about the same amount as the British Empire and United States combined.

ITALY

Italy lacks oil, coal, lignite, iron, copper, and most of the ferro-alloy metals. To this extent she is a heavy liability to the Central European war machine. For example, her civil consumption alone of oil and oil products was 3 million tons in 1938 and again in 1939, of which only 220,000 tons each year were supplied by Italy and Albania. This is not counting the heavy war consumption for her fleet, air force and mechanized columns in Africa. Therefore so soon as stocks are exhausted she will compete with Germany for Rumanian oil. The same applies to nearly all the indispensable metals.

There is, however, another side to the picture. Many of the other minerals are plentiful in Italy, and in at least two of them, mercury and sulphur, she easily heads the world's production. These and several of the other minerals produced by Italy happen to be scarce in Germany—especially bauxite, lead, and asbestos. In exchange for them Germany finds a market for some of her superabundance of coal and potash.

Sulphur. The Sicilian sulphur belt is by far the most important deposit of native sulphur in Europe, if not in the world. Italy accounts for 80 per cent of the European production.

Pyrites. Italy also has the third largest pyrites production in Europe.

Mercury. The cinnabar deposits of Idria (formerly in Austria) make Italy the world's leading producer of mercury. The only other large-scale European deposits are in Spain.

Zinc and Lead. In 1937 Italy accounted for 16 per cent of the European zinc production and 13 per cent of the lead. The mines are mainly in Sardinia. Her average production over a number of years has been maintained at more than 77,000 tons of metallic zinc and more than 25,000 tons of metallic lead annually.

Manganese. Italy takes third place with 19 per cent of the European production of metallic manganese from high-grade ores, and it is believed that she is self-sufficient in this metal.

Aluminium. Italy also takes third place in the production of bauxite, with 18 per cent of the European total. Her reserves, however, are relatively small.

Antimony. Production is sporadic ; but in 1937 Italy occupied third place with 14·6 per cent of the European production.

Mica. In 1938 Italy occupied second place among European countries producing mica, the order being: Sweden with 129 tons, Italy with 120 tons, Norway with 102 tons, and Rumania with 22 tons.

Asbestos. Italy is a close second after Finland in the production of asbestos ; but although she produces 39 per cent of the European total the amount is small, since Europe's production is only 3 per cent of the world's total. The Italian production is only equivalent to about a quarter of Germany's imports.

(*To be continued.*)

OBITUARIES

Sir George Grierson, O.M., K.C.I.E.

SIR GEORGE GRIERSON, who died at Camberley on March 7 at the age of ninety, was the most distinguished of the select group of Indian officials who carried out invaluable philological, ethnographic or historical studies in addition to their official duties.

Before entering the Indian Civil Service in 1873, Grierson had already acquired an exceptional knowledge of Sanskrit and Hindustani. His early service was spent mainly in Bihar, where he made an intensive study of the local vernaculars. When he had been only ten years in the country, he published his "Seven Grammars of the Dialects and Sub-Dialects of the Bihari Language".

Grierson was nominated by the Government of India as its representative at the Congress of Orientalists held at Vienna in 1886. At this Congress, a resolution was passed urging the Government of India to undertake a linguistic survey. Some years elapsed before anything was done, but in 1894 it was decided to accept the suggestion, and Grierson was appointed superintendent of the Linguistic Survey of India. His first step was to obtain from each district a list of all the languages and dialects spoken in it, together with uniform specimens of each. The preparation of these specimens, in the case of the lesser known languages, had often to be entrusted to persons of inferior education, and they had to be subjected to most thorough scrutiny and revision before they could be accepted as correct. This preliminary operation lasted four or five years. The processes of digesting and collating the raw material thus provided necessarily took much longer. Each specimen had to be subjected to close analytical study in order to ascertain its grammatical structure and other peculiarities, and to decide whether it should rank as an independent language or a dialect, and to what linguistic family it should be assigned. The final stage was the preparation of a classified scheme of linguistic families, sub-families, languages and dialects, and the arrangement, editing and annotation of the specimens.

The "Introductory Volume" in which the final results were reviewed, was not published until 1927, thirty-three years after the inception of the work. The enormous labour involved will be understood when it is noted that, in all, 179 languages and 544 dialects have been recognized, and that the report extends over twenty bulky quarto volumes.

Many of the principal languages were, of course, already well known, and had been the subject of investigation by a number of scholars, notably Caldwell, Beames, Max Müller and Hoernlé. But even in their case, Grierson was able to establish new conclusions, including the differentiation of "Hindi" into three distinct languages, and the recognition of Lahnda as an independent language and not a mere dialect of Panjabi.

Among the lesser-known vernaculars he made an intensive study of Kashmiri and other Pisacha languages. Of the 132 Tibeto-Chinese languages examined, grammars and vocabularies had already been compiled only for about twenty; most of the others had never previously been reduced to writing.

The Linguistic Survey of India represents an unparalleled achievement. It has been universally recognized as such, and learned societies and universities in many different countries have vied with each other in showering distinctions upon the man responsible for it. Grierson's final honour was the O.M., which was conferred on him in 1928.

Grierson was the author of other books, too numerous to mention in a brief review, and of many papers in the journals of Oriental societies. Although languages were always his main preoccupation, his interests covered a very wide field. For example, his "Bihar Peasant Life" has been described as "an encyclopædia of information about the people of Bihar". He was for many years the mainstay of the Asiatic Society of Bengal and afterwards a leading member of the Royal Asiatic Society.

Apart from his great attainments and industry, Grierson's most marked characteristic was the unselfish assistance which he was always ready to give to other workers, however humble. I, myself, gratefully remember the trouble that he took, though I was then a stranger to him, in making my first contribution suitable for publication in the journal of a learned society. At the Census of India in 1901, and again in 1911, Grierson freely placed all the facts which he had until then ascertained at the disposal of the Census officers, so that they could utilize it in their reports, before he had himself published it. He gave immense help to the Bible Society in the preparation of vernacular versions of various parts of the Bible. E. A. GAIT.

Dr. A. T. Masterman, F.R.S.

THE late Dr. A. T. Masterman was superintendent inspector of fisheries to the Board of Agriculture in 1910, when the Board took over the international fishery work of the Marine Biological Association. From then onwards Masterman directed the scientific fishery work of the Board, but his interest in the commercial possibilities of various scientific discoveries culminated in his relinquishing his post to engage in business enterprises. On the resumption of the scientific fishery work in 1920, the task of reorganization fell to Prof. Stanley Gardiner.

During his administration of the scientific branch of the Fisheries Department, Masterman found time to write three papers on the age and growth of various fresh- and brackish-water fish, all of which showed a balanced critical view of the technique, and among which his paper on the salmon of the Wye should be known to all interested in salmon. He kept a large staff of scale-readers busy. He published also several important papers on the plaice fisheries of the North Sea.

In pure zoology Masterman will be remembered for his attempt in 1896–1901 to place the burrowing worm-like animal Phoronis near Balanoglossus and the vertebrate ancestry. The evidence came from the internal anatomy of the larva (Actinotrocha). This thesis was contested by many, including Roule, to whom Masterman replied with dash and vigour, but in 1904 de Selys Longchamps claimed to remove Masterman's edifice stone by stone. Ikeda, Goodrich and Shearer all disagreed with Masterman on one point or another. Although in 1910 Harmer in the Cambridge Natural History, put Phoronis in the Hemichordata on the basis of Masterman's observations, 'if confirmed', MacBride in 1914 in his "Text-book of Embryology" feared that Masterman's "fascinating" theory could not be upheld and put Phoronis with Sipunculus in Podaxonia (*Gephyrea nuda*). In the 1921 (revised) edition of Parker and Haswell's text-book Phoronis remains with the Brachiopoda and Polyzoa under Molluscoida. However it ended, Masterman's initiative evidently led to substantial additions in knowledge of Phoronis and its interesting larva.

Masterman was seventy-two years old when he died on February 10, but, as may happen when reviewing the work of scientific workers who reached administrative posts early in life, the search for the man's own work is most productive when we go to the early years, in Masterman's case to the time when he was less than thirty years old. From 1893 until 1899 he was assistant to Prof. W. C. McIntosh at St. Andrews, and collaborated in a book that can be called a masterpiece, "The Life Histories of the British Marine Food Fishes", published in 1897. The only part of the book that is stated to be Masterman's separate contribution is a general chapter on growth, and this must be judged against its background, when almost nothing was known on the subject except for the papers which this young investigator had already published. The chapter, which is an essay, undoubtedly had considerable value forty-four years ago, when nothing was known of the technical methods that have been so fruitful in the intervening years, and the graphical method that Masterman used is still the only one available for some populations of fish. The main bulk of the book is stated to be joint work. It consists of notes on life-histories of no less than eighty-seven species of fish—a remarkable treatise to have been produced only a few years after the eggs and fry of many of the species had first been identified. To collaborate in that work was a worthy achievement.

Indeed, Masterman at St. Andrews was a member of a notable company who studied at the Gatty Laboratory and went out to make marine biology as we know it. Some of us who only knew the members as men of middle age and older, wonder what the company was like; but are certain that it was both gay and learned, for it included, at one time or another, Holt, Prince, Kyle, Williamson, Calderwood, Wallace, Meek, and D'Arcy Thompson. To them Masterman, scholar of Christ's and Darwin Prizeman, brought the speculative turn of mind that is shown by his papers and the gift of lively companionship that his contemporaries recall.

M. GRAHAM.

Dr. William Doberck

WILLIAM DOBERCK was born at Copenhagen on September 12, 1852, and died at Sutton, Surrey, on January 5 of the present year. He had long been well known as one of the most enthusiastic and assiduous of workers in the field of double-star astronomy.

Dr. Doberck began his observations at Markree, Ireland, in 1874, at the observatory of Col. E. H. Cooper, at that time H.M. Lieutenant for County Sligo; but later worked in various parts of the world, including Kowloon. Eventually he settled at Sutton, where he set up an observatory equipped with a 6-in. refractor and continued his double-star measurements until 1927. His sets of measures, which were very numerous, amounting altogether to something like 13,000, were nearly all made with rather small instruments, but included several pairs of which the angular separation was less than 1″. The observations at Markree were published in the *Transactions of the Royal Irish Academy*, vol. 29, part 13, and the remainder in various issues of the *Astronomische Nachrichten*. Eventually, Dr. Doberck collected them all together and published them in vol. 7 of the *Astronomische Abhandlungen*.

But Dr. Doberck was not only an observer; he was also a computer of orbits. In his book "The Binary Stars", published in 1918, Dr. R. G. Aitken referred to him as "the man who has investigated more double-star orbits than any other astronomer". Doberck also inquired into other problems relating to binaries, such as a possible parallelism of the orbit planes, in regard to which his investigation led him to a negative conclusion. He also at one time gave attention to variable stars. It is as an exceptionally diligent and successful student of visual double stars that he will always be remembered.

T. E. R. PHILLIPS.

WE regret to announce the following deaths:

Dr. E. J. Gwynn, formerly provost of Trinity College, Dublin, on February 10.

Dr. P. N. Leech, director of the Division of Foods, Drugs and Physical Therapy in the headquarters office of the American Medical Association, aged fifty-two.

Sir William Smyly, formerly master of the Rotunda Hospital, Dublin, and president of the Royal College of Physicians in Ireland, on March 19, aged ninety.

Dr. Michel Weinberg, of the Pasteur Institute, Paris, known for his work on parasitology and anærobic bacteria.

NEWS AND VIEWS

Guthrie Lecture of the Physical Society

PROF. E. N. DA C. ANDRADE, Quain professor of physics in the University of London, is delivering the twenty-fifth Guthrie Lecture at a meeting of the Physical Society in the Royal Institution on April 4. The lecture is entitled "A Problem of Guthrie's Time" and its subject is sensitive flames, or rather sensitive jets in general, one of the types of acoustical investigation so elegantly and so successfully carried out by Prof. Andrade and his students at University College, London. It was at that college that Andrade started his research career. From there he went to Heidelberg to work under Lenard on the electrical properties of flames; for this work, in which he established, for the first time, the true velocity of the positive ions, he obtained his Ph.D. *summa cum lauda*. Returning for a further year to his old college, of which he became a fellow, he established the laws of the flow of metals under constant stress, and prepared the first single crystals of certain metals, including solid mercury. He then went to the Cavendish Laboratory for a year, and afterwards to Manchester, where he carried out, with Rutherford, the first determination of wave-lengths in the gamma-ray spectrum. During the War of 1914–18, Prof. Andrade saw active service in the R.G.A., and was mentioned in dispatches. Afterwards, he was appointed professor of physics in what was soon to become the Military College of Science, Woolwich, where he built up a physics department *ab initio*, put the teaching of physics on a sound footing, and did everything that was possible to foster active experimental research in his department.

In 1928 Prof. Andrade was appointed to the Quain chair of physics at University College, where he resumed work on single crystals and established a flourishing school of research. Here, too, he has done fundamental work on liquid viscosity and on acoustics, including investigations on Kundt's tube in the most general aspect, and also on sensitive jets, which form the subject of his Guthrie Lecture. Every item of his experimental work displays the marks of extreme thoroughness and great beauty. Prof. Andrade is widely known as a brilliant exponent and an original popular lecturer. His books have the same excellent qualities as his researches and his lectures; among them are "The Structure of the Atom", which very quickly reached a third edition, "The Atom" (a smaller book), "Engines", and "The Mechanism of Nature" (which has been translated into six European languages). In addition to his scientific work, he has found time to maintain his old activities and interests in poetry, and as a collector of old books.

Iron and Steel Institute: Bessemer Gold Medal

DR. THOMAS SWINDEN, who has been awarded the Bessemer Gold Medal for 1941 of the Iron and Steel Institute, is director of research in the United Steel Companies, and a director of Messrs. Samuel Fox and Co. Ltd. He studied metallurgy at Sheffield under Prof. Arnold, being awarded the Mappin Medal and gaining an 1851 Exhibition scholarship, with which he went to Sweden, working in the University of Uppsala and in Swedish steel works. Returning to England he entered the firm of Samuel Fox and Co. at Stocksbridge, near Sheffield, where he installed a laboratory for physical testing. When the firm became part of the United Steel Companies, Dr. Swinden took charge of the research work of the combined firms, and in 1934 the exceptionally well-equipped Central Research Department at Stocksbridge was opened. By the organization and staffing of this laboratory, he has done much to advance the application of science to the iron and steel industry.

Dr. Swinden's own investigations have included the first detailed study of the tungsten steels, carried out partly at Sheffield and partly at Uppsala. This laid the foundation for all later work on tungsten steels, and was followed by a similar exhaustive study of molybdenum steels, for which he was awarded the Carnegie Gold Medal of the Iron and Steel Institute. His later work has dealt with the properties of cold-rolled steel and with the control of grain size in steel. As chairman or vice-chairman of research committees, he has rendered valuable service in connexion with researches now in progress, especially on the problem of oxygen in steel and on the improvement of refractory materials.

University of Bristol: Chair of Anatomy

PROF. S. E. WHITNALL has retired from the chair of anatomy in the University of Bristol on reaching the retiring age. His going will be a loss to British anatomy in many ways, for he was far more than an anatomist. He was a contributor to the columns of *Punch*, and the author of that most human little publication "The Study of Anatomy". Had Prof. Whitnall never made any other contribution to the study of anatomy, that publication would have endeared him to many. To his contemporaries he will ever be remembered as the most humorous and human of companions; to the present generation he may be no more than the respected author of the "Anatomy of the Human Orbit". But despite the attack of the B.N.A. on eponymous nomenclature, he may claim in 'Whitnall's tubercle' to be the only living anatomist whose name remains attached to a definite structure in the human body. His last rival in this regard was the late C. B. Lockwood of St. Bartholomew's. Prof. Whitnall hails from Lancashire and he entered Owens College in 1894. Afterwards he was associated with St. Thomas's and for long with Oxford. In 1919, after war service with the Oxford Hussars, he went as professor of anatomy to McGill University, Montreal. There he remained until 1934, when he took the chair at Bristol, from which he is now retiring.

Dr. J. M. Yoffey has been appointed to succeed Prof. Whitnall in the chair of anatomy in the University of Bristol. Like his predecessor, Yoffey is a Manchester man, qualifying from the University of Manchester in 1926. Dr. Yoffey has had a brilliant career both as a student in Manchester and as a teacher at University College, Cardiff. More than this, he has had the great advantage of a Rockefeller Scholarship, which enabled him to carry on his researches in the United States in association with Prof. Drinker. As a research man Yoffey's name is permanently associated with the problems of lymphatics and lymphatic pathways. In this realm he has won wide recognition by reason of the thoroughness and the accuracy of his methods. When, in the post-War period, the Anatomical School of Bristol is reconstructed, we may look to see it as the centre of active investigation and research, and as the department to which many will go for inspiration and for knowledge of one of the most important subjects in which human anatomy impinges on clinical investigation.

Marine Biological Association's Laboratory: Air Raid Damage

DURING the recent air-raids on Plymouth, the Laboratory of the Marine Biological Association suffered severely. The buildings, though still standing, have sustained heavy damage. All windows except a few on the south side of the top floor of the main building have gone; ceilings are down, doors wrenched off, and much structural damage caused by blast. The director's house was completely burnt out. The Library, very fortunately, is intact except for the loss of windows and the skylight, and it has now been made waterproof. At the eastern end of the north building damage is most severe, but the greater part of the equipment and apparatus is intact. The Easter-class house will no doubt have to be rebuilt, but most of the roof remains. Other outbuildings, including the dogfish house, director's garage and stores, and the constant temperature rooms, have all sustained damage. The exact extent of the structural damage to the buildings cannot be determined without expert assistance, but it is hoped that the laboratories themselves can be restored. The tanks on the north side of the Aquarium burst and the supply pipes broke, but it is hoped that some part of the circulation may be restored before very long.

It will evidently be a long time before permanent repairs can be undertaken. Since materials for urgent work are extremely short, the cellotex sheeting on the first and second floors of the main laboratory is being taken down and used to replace windows. It is hoped to fit a small glass pane in each room, and if the cellotex is well painted, it is expected to remain weatherproof for a year or two. In a few weeks it may be possible to accommodate research workers who require only limited facilities, but this must depend largely upon the restoration of electricity and water supplies. There is no difficulty concerning general administration, as most documents have been salved. For the time being it will not be possible to supply orders for specimens, but it is hoped that in the course of a few weeks some of the normal facilities will be available.

University of Glasgow: Air Raid Damage

WHILE the University of Glasgow has as yet received no direct hit during recent air raids, all the windows of the main University buildings facing the park have been shattered. The Departments of Physiology, Public Health and Zoology have lost most of their windows, while many window frames and ceilings have been damaged. Some of the class rooms are temporarily unusable. Fortunately the damage to the contents of the buildings is quite negligible, and none of the personnel, staff or students, was injured although there were fire patrols in all the buildings. No other scientific institution in Glasgow appears to have been damaged.

City Museum, Leeds: Air Raid Damage

DURING recent air raids, the City Museum at Leeds suffered. The principal damage was done to the bird room and to the collections of medals and local tokens. Cases containing geological, archæological and zoological exhibits suffered from blast, but their contents are intact. Generally speaking, a large percentage of the disturbed material can be recovered. A collection of birds eggs survived a fall of 20 feet.

Annals of the Botanic Gardens, Buitenzorg

UNTIL recently the *Annales du Jardin botanique de Buitenzorg* were published at Leyden. As the European territory of the kingdom of the Netherlands is now occupied by the Germans, a new series under the title of *Annals of the Botanic Gardens, Buitenzorg*, has been started at Java. This periodical will cover the whole field of pure botany, including plant physiology, morphology, anatomy, cytology, ecology and microbiology. It will contain contributions by the regular staff and visitors of the scientific institutes of the Botanic Gardens, as well as from other sources. The editors mailing list is, however, not available in Java. As it is intended to continue exchange as usual, it is necessary to renew or confirm each exchange. The same holds for subscriptions to the new series. The price per volume is fixed at fl. 10. Therefore, subscribers and other persons interested in this periodical should communicate with the Director of the Botanic Gardens, Buitenzorg, Java, Dutch East Indies.

Botanists of the Second Millennium B.C.

AN interesting short paper by Prof. F. E. Weiss (*J. Roy. Hort. Soc.*, 66, Pt. 2, February 1941) directs attention to the "Court of Flowers" in the Festal Temple of Thutmosis III (1501–1447 B.C.) at Karnak. This ruler aspired to, and attained by conquest, a considerable empire in Syria and Palestine. He appears to have been unique in that he ordered botanical exploration to follow totalitarian imposition, and published his results as bas-reliefs upon the walls of the Court of Flowers at Karnak. Many species are unidentifiable, but others cannot be mistaken. These include the blue water lily, *Nymphœa cœrulea*, the pomegranate, vine, two species of arum (*A. italicum* and *A. Dracunculus*), a species of Kalanchoë and one of Iris. The fruits of sycamore (*Ficus sycomorus*) and a capitulum of *Chrysanthemum coronarium* are less certain, though probable, namings. It is rather curious that some of the species are now regarded as native in Egypt, but this lithological publication of botanical geography distinctly speaks in hieroglyphic inscription of "all the beautiful flowers which the power of His Majesty has collected when His Majesty was making war on upper Palestine so as to conquer the countries".

Food from the Poppy

Temperate regions have relatively few oil-yielding plants, and under the stress of war-time needs, Dr. R. Melville makes the interesting suggestion (*Gard. Chron.*, Feb. 8) that the oil (opium) poppy, *Papaver somniferum*, would be a suitable crop to grow in Great Britain as a source of fatty nourishment. The seeds have a pleasant, nutty flavour, and contain about 50 per cent of edible oil, with 20 per cent of protein. It is thought that yields of 8 cwt. of seed per acre should be possible in the climate of Great Britain. The seeds do not contain any toxic or narcotic substances, and the most potent vindication of the suggestion is that about twenty acres of the crop used to be cultivated regularly in the Isle of Axholme.

Czechoslovakia: Twenty Years of Independence

UNDER the above title, Prof. R. J. Kerner of the University of California, Berkeley, U.S.A., has edited a comprehensive and frank appraisal of the cultural, scientific, educational and social progress achieved by the Czechoslovak nation during the two decades it was in charge of its own destinies (University of California Press. Pp. xxii + 504. 5 dollars. 1940). As this work of more than five hundred pages shows, the record is a remarkable one and its very greatness makes all the more poignant the circumstances whereby the nation lost its independence. In producing this important work Prof. Kerner had the co-operation of twenty distinguished British, American and Czechoslovak scholars possessing first-hand knowledge of their subject. Thus, Prof. Aleš Hrdlička, of the Smithsonian Institution, writes authoritatively on Czechoslovak anthropology. Other writers trace the nation's history, its humanitarian progress, educational policy, music, arts, science and literature.

There are sections on the Little Entente, Czech democracy, social and religious legislation, and a valuable chronology tracing the fundamental happenings which concern the Czechoslovak peoples from 500 B.C., when Gaulic-Celtic tribes inhabited the land, "until July 21, 1940, when the new republic was recognized by Great Britain". Czechoslovakia is not a dead issue, for within the limits of that State and integrated in that people are the fundamentals of all that democratic Governments believe in and all that individual right holds as its standard.

The Resources of India

A RECORD and a review, 1939–1940, "India at War" by Sir George Dunbar, with a foreword by Field-Marshal Lord Birdwood, which has just been issued by the Ministry of Information, acquires further interest from recent developments and in the Near and Far East. Sir George Dunbar reviews briefly the help which India has given and is giving in the war against Nazism, including the expansion of her fighting forces, the loyal response of the Indian States and India's economic effort. Great increases are being made in the fighting services, but the most valuable and immediate help India can give is industrial. Sir George reviews India's potential economic reserves in relation to strategy and the conservation of shipping, stressing the importance of her contribution in oils and fats, jute, rubber, hides and skins, etc., as well as the striking development of the iron and steel industry. India is computed to be turning out 90 per cent of her own requirements as well as meeting overseas orders for ammunition, explosives, military equipment and clothing, while the manufacture of aluminium is beginning and aircraft construction is under consideration.

The Grand Coulee Dam

ON March 22 the official opening took place of the great hydro-electric and irrigation scheme on the Columbia River, Washington, across which the Grand Coulee Dam has been erected. The River Columbia rises in the Rocky Mountains in British Columbia, and after crossing the Canadian boundary flows through the State of Washington to the Pacific Ocean. Its lower courses form the boundary between Washington and Oregon. The scheme has been designed for the generation of electric current and for irrigation purposes. The concrete dam, which impounds water in the 150-mile stretch up to the Canadian boundary, is 4,200 ft. long with a maximum height of 553 ft. Its mass is greater than the Boulder Dam, and its construction—details of which are now being published in the *Engineer*—has taken about eight years.

When completed there will be two power houses with twenty-one generators with a total capacity of about 1,974,000 kw., but the first load was of only about 10,000 kw. At the west side of the dam will be a pumping house with twelve large electrically driven pumps raising water from the reservoir into a vast balancing basin from which the water will be distributed by a series of canals, over an area of

1,200,000 acres of land, now dry and barren, thus providing farm land for some 75,000 people. The irrigated area, it is expected, will ultimately be the home of more than a million.

Tuberculosis in the Navy

AT a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on March 28, Surgeon-Rear-Admiral S. F. Dudley and Surgeon-Commander W. G. C. FitzPatrick read a paper on epidemiology in the Royal Navy, especially as regards the use of miniature radiography. They stated that tuberculosis is an occasional disease of sailors. Although its ravages were much greater in the last century, there has been no decline in its prevalence in the present century, in spite of energetic measures to prevent it. This is due to the unpreventable degree of overcrowding which must exist in warships and the presence of numerous unsuspected cases of open pulmonary tuberculosis. Measures designed to weed out these sources of infection have hitherto failed; little effect on total incidence can be expected from the X-ray examination of recruits or limited numbers of contacts. Periodic X-ray examination of the total force by the usual technique is considered impracticable, therefore the more rapid and economic technique of mass miniature radiography has been instituted. Some preliminary results on the first twenty thousand examinations were given and the organization of the first Naval Miniature Radiographic Department was described.

Jewish Population of Palestine

THE Statistics Department of the Jewish Agency Executive records that the Jewish population of Palestine has increased by immigration and natural increase from 174,606 in November 1931, according to the official census of that time, to 488,600 in September 1940. This estimate is 30,000 higher than that of the Government, which puts the Jewish population at 456,743 in June 1940. The Jews now represent 31·2 per cent of the settled population of Palestine. In 1931 the percentage was 16·9, and in 1922, when 83,790 Jews were enumerated after the British occupation, it was 11·1.

Health of Iceland

ACCORDING to the latest annual report of Dr Vilmundur Jonsson, director of public health, health conditions in Iceland are generally satisfactory. The death-rate is 10·2 per 1,000, and the infantile mortality-rate of 29 per 1,000 is remarkably low; deficiency diseases are infrequent, rheumatic fever and diabetes are rare, and diphtheria, which was once very fatal among children, is now kept in check by immunization. On the other hand, there is a relatively high rate for tuberculosis, and pneumonia is an important cause of death.

Steel Armouring of Cables

MR. R. W. L. PHILLIPS, borough electrical engineer of Bedford, has an article in the *Electrical Review* of January 10 on the present prohibition of steel armouring on electric cables. In the early days of electricity supply, the practice of laying cables direct in the ground without conduits or some similar protection was looked upon by many as being risky, principally because in many soils the lead sheathing would be liable to attack by corrosive salts. As a matter of fact, this did occur until a suitable compound was found for impregnating the protective jute covering. Armouring was added as a safeguard against mechanical damage. The usual method that is adopted to protect a cable that is to be laid direct in the ground, is to 'serve' the lead sheathing with a layer of jute before laying on the armouring, and a further layer of impregnated jute to protect the armouring from the corrosive action of the soil. The first layer acts as a bed for the armouring, thus preventing it damaging the lead; but, in Mr. Phillips's opinion, the success of direct-laid underground cable is due not so much to the armouring as to the double layer of impregnated jute so made necessary.

It remains to be considered whether the armouring of the cable, as normally provided, is a sufficient mechanical protection to justify its expense and the use of so much steel which is urgently required for other purposes at the present time. Mr. Phillips's experience in Bedford is helpful here. In this borough some 230 miles of medium voltage cable, 80 miles of cable up to 3,000 volts and about 45 miles of higher voltage cables, all without armouring, were laid in the ground. In the manufacture of unarmoured cables for direct laying, it is in some cases the practice to provide the cable with two layers of impregnated paper directly over the lead, as a protection against chemical action. This is followed by a final covering of two layers of doubly impregnated jute. If it could be done without unduly putting up the cost of manufacture, a better method would be to 'braid' the final jute covering under a stream of compound when manufacturing the cable. There are two incidental advantages in the use of an unarmoured cable. It weighs less, which affects both transport and handling; it is easier to joint (this is especially useful when making service connexions to low-voltage distributors). Mr. Phillips quotes data in connexion with an extensive and intensive electrification of a rural area of about 200 square miles. In the majority of the villages in this area it actually cost less to lay unarmoured low-voltage distributors than to provide the same service by means of overhead wires. Some of the cables in the Bedford area have been in the ground many years and no trouble attributable to the absence of armouring has been experienced.

Mummification in America

DR. ALEŠ HRDLIČKA, of the Smithsonian Institution, Washington, prefaces extracts from his diaries of 1936–38, when he was exploring for mummies on the Aleutian Islands, now appearing in the *Scientific Monthly* (January 1941), with some general considerations on the practice of mummification. As is well known, this practice has rather a remarkable distribution. In the ancient world it apparently remained limited to Egypt, though extending to some extent to the Canary Islands. In later times it was practised in the Torres Straits, and developed in two widely separate regions in the Americas—in Peru and the neighbouring territories and among the Gulf populations of Alaska, more particularly in the Aleutian Islands. Mummification, however, may be of two kinds: the natural, due to lack of moisture in climatic conditions; and the artificial, in which initially the internal organs are removed.

It will be remembered that the late Sir Grafton Elliot Smith was first stimulated to formulate his theories of the origin and diffusion of culture in and from Egypt by the identities in method in preparing the body for mummification in ancient Egypt and the Torres Straits—identities which he maintained were of such a highly technical character as virtually to preclude an independent origin. Dr. Hrdlička, without more direct reference to the controversial issue, points out that it is not known how the practice started in America. Origin in and transmission from Peru to Alaska seems far-fetched, but so too does the reverse process. It is difficult, however, to connect either region with Egypt. Yet such a connexion is not impossible; but until Siberia is more fully explored, the problem must be regarded as at present incapable of solution. In the meantime, it is noted that while the Egyptians embalmed the body and then bandaged it, the Americans used air-drying, stuffed it with moss or grass and dressed it in its best clothes.

Recent Earthquakes Recorded at Kew

Ten relatively large earthquakes have been recorded at Kew Observatory during the period February 2–March 16. The one which gave rise to the greatest amplitudes was that received on March 1, compressional at 3h. 57m. 22s. G.M.T., the epicentre being near Larissa in Greece (Nature, March 8, p. 292). The S wave arrived at 4h. 1m. 4s. G.M.T., L_Q at 4h. 2·5m., and L_R at 4h. 3m. There were three maxima, the first being the greatest, and having an amplitude of 150μ. The estimated epicentral distance from Kew was 2220 km., all calculations and readings being provisional. Three earthquakes were recorded on March 16. The first, at 7h. 54m. 17s. was probably from an epicentre 8480 km. distant, whilst the second at 16h. 38m. 52s. was most likely from an epicentre 1770 km. distant and may have been the shock reported to have been felt at Trapani and Palermo in Sicily. It gave rise to amplitudes of 35μ at Kew. The third shock, at 18h. 52m. 9s. beginning with a dilatational pulse, may have been an aftershock of the Palermo shock, though at Kew exact reading of the seismogram was difficult owing to confusion caused by microseisms.

Earthquake near New Guinea

The United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has made a preliminary determination of the epicentre of the earthquake of January 13, 1941. From reports received from the seismographic stations at Honolulu, St. Louis, Manila, Pasadena, Sitka, Logan, Chicago, Fordham, Philadelphia, Lincoln and College (Alaska), the epicentre appeared to be at latitude 3° S., longitude 144° E., which is in the Pacific Ocean north-west of Cape Girgir in New Guinea and almost due west of the Purdy Islands of the Admiralty Islands group. The depth of focus is estimated to have been near 100 km., which is not unexpected since the epicentre lies in a belt well known for the prevalence of deep focus earthquakes in the past. The initial time of the shock was probably 16h. 27·7m. G.M.T.

Periodicities in Solar Variation

Referring to the account of his paper on "Periodicities in Solar Variation reflected in Weather" published in Nature of October 26, 1940, p. 564, Dr. C. G. Abbot writes that, in the tabular matter in column 1, 24·9 months should read 25⅕ months, which later studies indicate to be preferable. It is also stated that the exact periods are given as the result of scattered *solar* observations made prior to 1920. This is incorrect. These values come from evidences of the solar periods in the *temperature* and *rainfall* records of Copenhagen, Vienna, and New Haven, 1800–1932. Further evidence will be given in a paper soon to be published in *Smithsonian Miscellaneous Collections.*

Announcements

The American Philosophical Society has made a gift of 10,000 dollars to the Royal Society "for the aid of science in Britain". This generous gift, from the oldest scientific society in the United States, is a welcome gesture marking the spirit of friendship between the men of science of the two countries, and emphasizing the determination of American scientific workers to aid their colleagues in Great Britain to carry on the pursuit of knowledge.

A discussion on "Vegetables as Food" has been arranged by the Nutrition Panel of the Food Group of the Society of Chemical Industry, to take place at the British Medical Association House, Tavistock Square, London, W.C.1, on April 9. The papers to be presented will deal with the chemical composition of vegetable foods, the planning of vegetable production, and the effects on nutritive value of cooking, canning, drying and other forms of preservation.

The Royal Society for the Prevention of Accidents states in the current number of *Safety Training* that there has been for some time a continued alarming increase in road accidents in children, despite all efforts of teachers, education authorities and parents. The increase has been attributed to absence from schools and the slackening of discipline in the early war months, and also to change of environment from city to rural life.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.*

In the present circumstances, proofs of "letters" will not be submitted to correspondents outside Great Britain.

Science and Government

The general control of scientific research by the State, which is envisaged in the article on "Science, Politics, and the Government" in the issue of Nature of March 8, is fraught with a more serious danger than any there discussed. There is little fear, if I know my countrymen, that our men of science will allow their research work to be biased by political, racial or religious considerations; or, indeed, that any pressure will be put upon them to do so when the excitements and passions of the present abnormal times have died down. The real danger is the one which Dr. O. Blüh points out so forcibly in his communication in the same issue of Nature: the danger to freedom of all kinds which is inherent in the very conception of the 'planned' state.

The applications of science to everyday life have become so important that it is, no doubt, natural and perhaps even desirable that society which reaps the benefits—and suffers the consequences—of this particular type of scientific activity should supervise and subsidize its further progress. Applied science is, however, only one aspect of research activity. The claim is now being made, in certain scientific circles, that utility on the material plane is the *only* justifiable motive for any research, and that all research should be directed and, if necessary compelled, to utilitarian ends. The assiduity and vigour with which this claim is pressed by its supporters is probably (as they would express it) "conditioned by their ideology", for few of them seem to be much influenced by the principle in their own research work. It is this claim against which Prof. Polyani was protesting in his communication to Nature. It is, however, a claim which is only too likely to appeal to a 'directing' government committee, however eminent its composition. Herein lies its danger.

"The fundamental point on which all can agree," as the article points out, "is that science represents the search for truth." The true motive for such a search is (to adapt the dictum of Plato) not utility but wonder. In spite of the difference in their working media, the man of science, philosopher, poet and artist belong to the same category; as anyone who has had the privilege of working under any of the great men of science of the age can easily realize. It is a class which cannot be 'organized' by any committee, and which does not respond to 'control' however well-intentioned. Yet the progress of science depends on such men's passionate pursuit of the truth. "The wind bloweth where it listeth", and to attempt to harness pure research to the chariot of utility would, if successful, only result in the gradual cessation of all progress. Modern materialism, masquerading under the name of 'scientific' planning, may well prove to be the most serious enemy which science has yet had to face.

J. A. Crowther.

The University,
Reading.

In Nature of March 8, Dr. E. C. Childs writes: "If we are deprived of experiment we must fall back on experience, that is, appeal to authority, which is admittedly less satisfying than scientific demonstration; and we cannot, as men of science lacking our chief weapon, expect to prevail in conflict with authority". Is not this a rather forced differentiation between "experiment" and "experience"? Experience is the outcome of the observation of facts. It surely does not matter whether those facts are obtained from a series of casual incidents or from pre-arranged reactions. There is no branch of science which does not owe a great deal to observation of casual—and frequently serendipitous—events. Admittedly it is convenient and convincing to be able to repeat as and when required an experiment to reinforce a specific argument, but that does not imply that experience is "less satisfying than scientific demonstration". As for "authority", "experiment" relies upon it quite as much as "experience", for the bulk of men have to accept the findings of the few specialists. In other words, they have to rely upon the authority which they accord to the expert.

When, then, Dr. Childs suggests that scientific men "should arm themselves with authority", he means no doubt that they should co-operate to insist on the observation of facts which they have gleaned by experiment and experience. They do that already through the Royal Society and a score of other influential bodies in subjects falling within their acknowledged spheres of influence; the suggestion is now that they should do it also in spheres —political and sociological—that are not usually recognized as within their ambit.

The question under debate is whether or not their training in precise observation and logical thinking fits them to do so better than other men who lack those qualifications. Surely a distinction must here be made between science and the scientific workers. It is devoutly to be wished that all men would consider political and, particularly, social problems, with the detachment from personal bias which ought to characterize scientific work. But the man of science is a human being like the rest of us, never simply and solely an observing and calculating machine, and he is swayed by the same emotions and subject to the same bias as his fellow men. There are many cases in which well-known men of science have shown themselves unable to bring logical thought to bear on non-scientific subjects.

Generally speaking, however, the scientific man is wholly honest, but unfortunately he is often a babe outside his own, sometimes a very narrow, field.

It seems then highly probable that your genuine man of science will only very rarely make a good legislator or a good administrator. But on the other hand, if he can inculcate the spirit of science, the scientific method, into sociological affairs, and if he can within his own sphere provide men of commoner clay with the facts from which proper deductions may be drawn, and if moreover he can present those facts with the authority to which Dr. Childs refers, is it not conceivable that he may be of greater service to his generation than if he takes a seat in Parliament or in political organizations ?

LOUGHNAN PENDRED.

The Athenæum.

THE admirable statement of the case in NATURE of March 8, p. 275, makes further comment unnecessary, but as I am referred to and as my letter in NATURE of January 25, p. 119, has been misinterpreted by some correspondents, perhaps I may be permitted to say that in advocating control by science after the War as a means of making good the destruction of wealth due to it, I did not intend to convey that men of science were to be in a position to dictate to the elected representatives of the people.

I am wondering if the following suggestion would be practicable: that a select committee or commission should be appointed to consider and report upon the best scientific methods of making good the ravages of war. An advisory council representative of all sciences might be set up, to whom all standing in need of scientific advice would have access, whether Government officials, farmers, industrialists, or whatever they may be. Sacred though freedom is, people ought not to be free to waste the national wealth in the present crisis by exploitation or unscientific activities.

ROBERT H. F. FINLAY.

Victoria Square,
Belfast.

Can Science be Independent?

PROF. A. V. HILL[1], in discussing State aid for science, directs attention to "the danger that he who pays the piper may call the tune, that research may be devoted primarily to objects which the politician, or the Civil servant, regard for the moment as of national importance", and demands that "the independence and integrity of science must be carefully safeguarded". A casual reader might suppose that in Great Britain before the War, men of science could choose their own field of research.

This is not the case. I am Weldon professor of biometry (defined as the application of higher mathematics to biological problems) not because I chose this topic, but because the late Mrs. Weldon left a large sum of money to endow a chair of this subject. I believe that I carry out my duties conscientiously, and I am doubtless lucky to find so congenial a post. But I should greatly prefer a chair of genetics which gave me more scope for experimental work. However, there is no such chair in England because no rich person has endowed one. In fact the fields of scientific research in Great Britain are to a considerable extent determined by the wishes of rich men and women. This is not independence. It is true that professors who are paid to devote themselves to one subject often carry out excellent research in another. Professors of human anatomy have given conspicuous examples. But it may be doubted whether this can always be done without a certain sacrifice of integrity, such as is made by clergy who interpret the creeds or the thirty-nine articles in a 'broad' manner which enables them to enjoy ecclesiastical emoluments whilst deviating from the purpose for which they were provided.

The plain fact is that science cannot be independent because it does not exist in a vacuum, and that complete intellectual integrity is very difficult except for those who are so fortunate that their opinions coincide at all points with those of their rulers.

Until such facts are realized, men of science will be likely to cherish the delusion that they can hope for complete liberty in a society where others do not share it. We can no more escape from a large measure of control by our social surroundings than from the earth's gravitational field. For this reason I believe that every man or woman of science should make some kind of study of social and economic relations in order to understand the conditions under which he or she must work.

I should like to go beyond Prof. Hill in one direction regarding his suggestions for co-operation with the fighting services. During the present War I have worked for all three. Some of the topics were very properly secret. Others, relating to hygiene in the broadest sense, were certainly not. Had certain of the problems under investigation been solved before the outbreak of war, a number of lives would have been saved. They would have been solved had biologists outside the services known of their existence. The barrier of secrecy around such questions has not merely protected the services from spying, but also from progress. In matters which concern the health and safety of personnel, there should be far more freedom of discussion than existed before the present War, and *a fortiori* vastly more than exists to-day.

J. B. S. HALDANE.

University College,
London, W.C.1.

[1] NATURE, 147, 251 (1941).

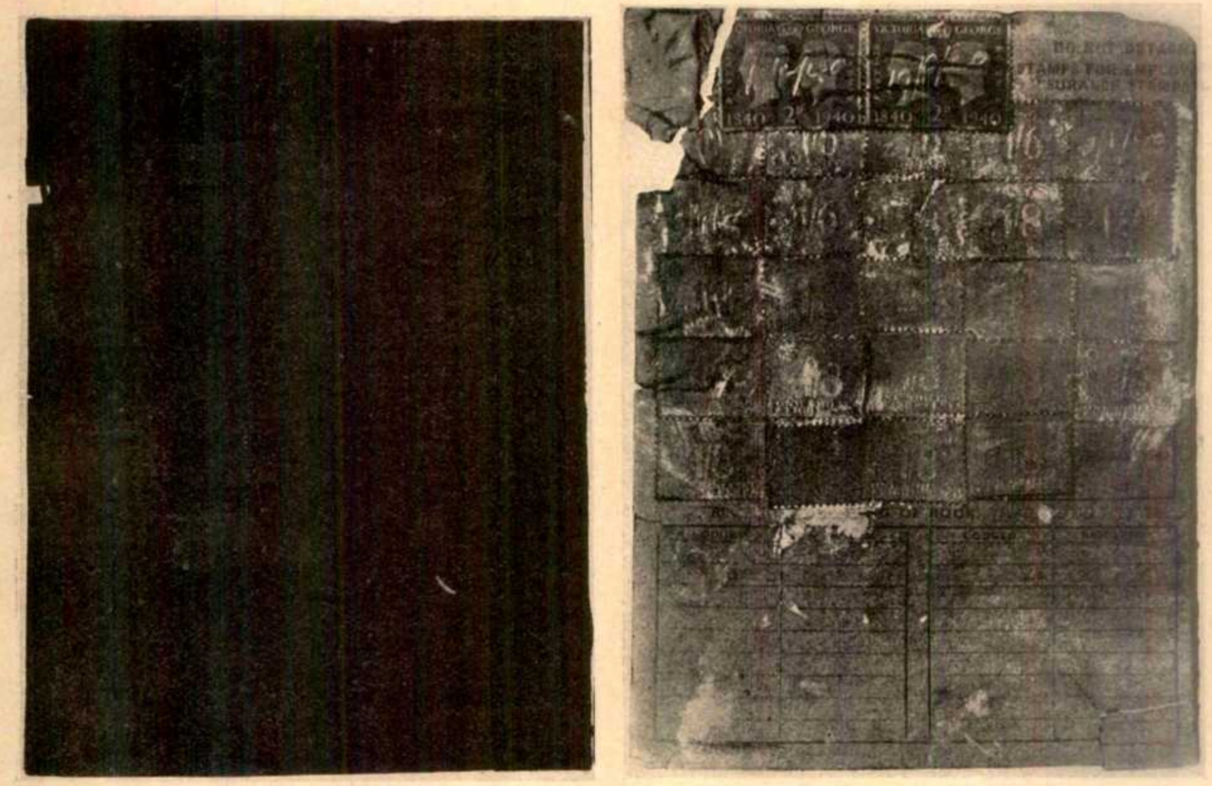
Prof. Haldane's denial that "before the War men of science could choose their own field of research" seems to be based on his own academic position—which is surely an exceptional one. By far the majority of university chairs are not endowed by private individuals, and most of them that are have no ultra-specific conditions attached to them. Prof. Haldane's statement that "the fields of scientific research in Great Britain are to a considerable extent determined by the wishes of rich men and women" savours of naïvety. Further, he states that there is no chair of genetics in England; this seems to overlook the Arthur Balfour chair of genetics at Cambridge, recently vacated by Prof. R. C. Punnett, and temporarily in suspense.

EDITORS OF NATURE.

A New Method for the Decipherment of Charred Documents

IN view of the widespread destruction by fire of documents of all kinds which is taking place at the present time, we think it desirable to put on record the preliminary results of some experiments in progress at this laboratory on the decipherment of charred documents. In spite of its topical interest, the subject is not a new one[1]; but we have already obtained results which we think, taking into consideration the simplicity and general applicability of the method, mark a distinct advance on anything hitherto recorded.

Briefly, the method consists in treating the document with chloral hydrate; this substance appears to exert an as yet unexplained 'clarifying' action on the burnt figures or letters. The chloral hydrate is applied in a 25 per cent alcoholic solution; after several applications, the document being dried at 60° C. between each, a mass of chloral hydrate crystals will form on the surface, and at this stage a similar solution containing 10 per cent glycerine is applied and the document dried as before. It may then be photographed. The most suitable type of plate is a contrasty non-colour sensitive one (for example, Ilford 'Thin Film Half-Tone').



PAGE OF AN UNEMPLOYMENT INSURANCE BOOK CHARRED DURING THE LONDON FIRE ON DECEMBER 29; BEFORE TREATMENT (LEFT) AND AFTER TREATMENT (RIGHT).

The accompanying illustration shows the type of results obtained. The method is equally satisfactory for typescript and for printing, and with certain modifications has been found to restore writing. Furthermore, the reading matter is restored equally on both sides of the paper.

Certain distinct advantages which are possessed by this method are: (1) it appears to be applicable to any type of document; (2) it is fairly quick; (3) it has never yet in our hands failed to produce a readable result; (4) it requires no special apparatus other than a copying camera.

It has so far eluded us to find a satisfactory explanation in physical or chemical terms of this action by chloral hydrate; but it is hoped that this problem will also be solved. Such a solution ought to put the method on a rational basis, and open the way for further advances. The allied problem of rendering the burnt document less brittle and more easy to handle during treatment is also being attacked.

We hope to publish a more complete account of these experiments in due course.

Our thanks are due to Dr. James Davidson, director of this laboratory, for permission to publish these results.

Criminal Law and Criminology*, 30, 236 (1939). (The first two sources give a number of references to earlier publications on the subject.)

Bacteriostatic Action of Nitrates

ALTHOUGH nitrites have been used officially in meat curing processes for well over a decade in the United States[1], it is only comparatively recently that their use has been permitted in Great Britain[2]. Undoubtedly, the predominant reason for their inclusion in cured meats has been the fact that they occasion a desirable colour in the finished product[3]; but it appears that they may also play an important part in producing a typical "cured" flavour[2]. When consumed directly, quantities of sodium nitrite in excess of 0·2 gm. may produce marked toxic effects in man[4] so that their use in foods must be strictly controlled. For this reason pure food regulations both on the North American continent and in Great Britain forbid the inclusion of more than 0·02 per cent (200 parts per million) of sodium nitrite in cured meats.

Very little attention appears to have been paid to the fact that nitrites may, under certain conditions, play an important part in retarding bacterial development on, and thus delay the spoilage of, meats and related products. Lewis and Moran[5] observed that growth of the mixed bacterial flora of minced beef in experimental brines was retarded by 0·03–1·5 per cent of sodium nitrite. Their work, as well as that of Tanner and Evans[6], indicates that the growth of strict anærobic bacteria of the genus Clostridium is inhibited only by relatively large amounts of nitrite. Other investigators[7,8] have observed that 0·4 per cent of sodium nitrite inhibits the growth of certain facultative anærobes. Thus most of the available literature has indicated that it is only rather large concentrations of nitrite, usually greatly in excess of the 0·02 per cent permitted by law, which will hinder or prevent bacterial development.

About two years ago experiments were carried out at this Station in which it was shown that bacterial spoilage of fish flesh is strongly delayed by incorporation of small amounts of nitrite salts[9]. The reason for this was sought, and it was found that bacteria are only susceptible to low concentrations of nitrites at *p*H values below 7·0, and that the muscle of fish shortly after capture becomes sufficiently acid (for example, *p*H 6 to 6·6) for these salts to exert their bacteriostatic action[10]. Not all bacteria studied have proved equally susceptible to nitrite, and certain organisms do not appear to be inhibited. However, growth of species of the following bacterial genera at *p*H 5·7 or 6·0 has either been markedly inhibited, or in certain instances entirely prevented, by 0·02 per cent of sodium nitrite: Achromobacter, Flavobacterium, Pseudomonas, Micrococcus, Escherichia and Aerobacter (also one species of Torula)[11].

Attempts have been made to determine by what mechanism nitrites exert their inhibitory action. The possibility that they act by combining with respiratory hæmatin compounds suggested itself, especially in view of the fact that Ingram[12] has found that oxygen uptake in the case of the aerobic, cytochrome-containing organism, *Bacillus cereus*, is very strongly inhibited by traces of nitrite. However, it has been found that there is no apparent relationship between inhibition of growth by nitrite and its effect on respiration. Thus in certain instances growth of a given organism was strongly or completely inhibited at *p*H 6·0 by 0·02 per cent sodium nitrite, whereas under similar conditions its aerobic respiration was not significantly inhibited[11]. The possibility that salts of this type inactivate certain enzymes by combining with their amino groups as was originally suggested by Quastel and Wooldridge[13] must not be overlooked. Since it has recently been shown that certain organisms remain viable after exposure to 38·8 per cent sodium nitrite at *p*H 3–8 for ten minutes[14], it would appear rather unlikely that nitrites are able to act in a bactericidal capacity.

β-Glucosaminase in Testes

DIFFUSING factor preparations from various sources cause a rapid decrease in the viscosity of certain mucins (for example, hyaluronic acid) and if contact is maintained for a longer period hydrolysis of the polysaccharide can be detected by an increase in the reducing power of the mixture[1]. Since the mucins in question are believed to be built up of N-acetylglucosamine and uronic acid residues it seemed likely that an enzyme capable of hydrolysing them would also hydrolyse other N-acetylglucosaminides. It has, in fact, been demonstrated (see accompanying table) that a concentrate of testicular diffusing factor[2] will hydrolyse N-acetyl-β-phenylglucosaminide much more readily than any other glycoside examined.

	Time of incubation at 37° C. (hr.)			
	1	2	6·5	24
	% hydrolysis (Bertrand)			
N-acetyl β-phenyl glucosaminide	4·6	9·3	18·7	28·4
β-phenyl glucoside	1·3	1·3	1·8	3·3
Salicin	0	0	1·5	1·8
Sucrose	1·7	1·7	3·3	2·7
β-menthyl glycuronide	0	0	0	0

The optimum *p*H for this β-glucosaminase (4·8) is close to that at which diffusing factor preparations exert their maximum effect on the viscosity of hyaluronic acid[3]. There are, however, certain facts which suggest that the two effects—decrease in viscosity and increase in reducing power—may not necessarily be due to the same enzyme. When mucins of the hyaluronic acid type are treated with $M/5$ HCl or $M/5$ NaOH at 25° C. a gradual and irreversible decrease in viscosity occurs. Glycosidic linkages are, as a rule, stable to alkali under these conditions, and it may well be that the viscous material contains linkages of some other type. Moreover, crude emulsin preparations which show β-glucosaminase activity do not affect the viscosity of hyaluronic acid.

A more detailed account of the β-glucosaminase activity of testicular extracts and its bearing on the problem of diffusing factors will be published elsewhere.

RESEARCH ITEMS

Stone Implements from Ceylon

A collection of stone implements made by N. A. and H. V. V. Noone during a three months visit to Bandarawela numbers some two thousand specimens which have been classified systematically (*Ceylon J. Sci.*, Sect. G, **3**, 1 ; 1940). Several new types are included ; tentatively sixty types and varieties are differentiated. The richest sites are those reported by the Sarasins (1907) and Hartley (1913), but most hill crests not too far above the valley bed show vestiges of prehistoric man on or just below the surface. These finds were made mostly on the surfaces of the knolls and rises along the ridges of the grassy *patnas*, especially on the eastern brows, the larger pieces mostly on the slopes. Several specimens were extracted from a depth of 24 inches, but this is no criterion of age. Knapping tools and core-like pieces indicate working sites. With rare exceptions the material is quartz and rock crystal. Only at two sites was there a source of raw material available nearby. There are many indications of the use of derivative pebbles or blocks taken from neighbouring stream beds. Workmanship and technique are varied, rough and fine, heavy and minute specimens lying together. The longest implements are a cleaver (16·5 cm. × 11 cm.) and an anvil (13 cm. × 12 cm. × 4 cm.) ; the smallest a little less than 1 cm. The carefully worked symmetry of the dew-drop crystal is so skilled as to suggest adornment rather than utility. The main headings of classification are : *A*, polyhedrals ; *B*, bifaces ; *C*, flake and blade ; *D*, geometrical ; and *E*, special. There was no evidence of bone or shell industry. A few sherds of pottery, thick and thin, of coarse paste with a pattern-like cross-plaited grass matting, were found. Red hæmatite points to the use of ruddle ; one piece approached more nearly a polished implement than anything previously recorded from Ceylon. As a whole the implements cannot fittingly be described as neolithic. Their forms are rather palæolithic or mesolithic. Nor can they be correlated with European divisions and cultures. They warrant the claim that in Ceylon has been found one of the most highly developed prehistoric quartz and crystal industries as yet discovered and deserving of its own distinctive label—that of Bandarawelian being here suggested. So far as observed it shows no evidence of a local origin or of cultural division, nor has evidence of an earlier culture been seen.

Substances producing Cancer of the Liver in Mice

Japanese workers discovered that azotoluene and the azo dye, butter yellow, induce malignant changes in the livers of rats and mice. It is now shown (Cook, Hewett, Kennaway and Kennaway, *Amer. J. Cancer*, **60**, 62 ; 1940) that 1 : 1′-azonaphthalene, 2 : 2′-azonaphthalene and 2 : 2′diamino-1 : 1′dinaphthyl resemble 3 : 4 : 5 : 6-dibenzcarbazole in that they are able to induce malignant changes in the livers of treated mice although they do not produce such changes in rats. Cholangiomata were also found in mice which were treated with 1-methyl-3 : 4-benzphenanthrene, 2-methyl-benzphenanthrene, 2-*iso*propyl-3 : benzphenanthrene and 1 : 2 : 3 : 4-dibenzphenanthrene. On the other hand, 1 : 2′-azonaphthalene, a large number of carcinogenic compounds and a few azo dyes used for food colouring did not induce any new growth in the livers of mice. There is thus marked chemical specificity in the induction of liver tumours, although the change occurs with some hydrocarbons and some nitrogenous compounds.

Red Sea Xeniidæ

The Xeniidæ form a small but interesting family of the Alcyonacea, the order to which the common dead men's fingers belongs. The members of it found in the Red Sea have been described by H. A. F. Gohar (Publ. Marine Stat., Ghardaqa, Red Sea). This work is not simply descriptive, however, and its scope is best indicated by its sub-title "Their Ecology, Physiology, Taxonomy and Phylogeny". Indeed the bulk of the paper is concerned with observations upon the living animals, and the position of the laboratory has enabled these to be made under natural conditions. This is an aspect of our knowledge of the group that needed amplification. Three new species are described, although it is suggested that a study of the life-histories of the living animals will reveal that a number of the names in the group are synonyms. The author has also studied the preserved material in Cambridge, Edinburgh and London for the purpose of comparison. Besides the generally accepted genera Xenia and Cespitularia, the writer also puts forward reasons for including Heteroxenia, Sympodium and Anthelia in the family, of which he gives an emended and more complete diagnosis. Sympodium he considers deserving of inclusion in a sub-family Neoxeninæ, separate from the others, which he terms the Euxeninæ. They were derived from the main stock near the primitive Anthelia.

The Smut Fungi

Two papers have recently appeared in the *Transactions of the British Mycological Society* which increase our knowledge of the smut fungus flora of Britain and of India. Miss Kathleen Sampson has collected records of the seventy British species of the Ustilaginales, with full reference to published literature (*Trans.* **24**, Pts. 3 and 4, 294–311 ; Dec. 1940). The work was completed in accordance with recommendations from the Society's Plant Pathology Committee, and is a potent link between general field mycology and the kind of record-knowledge demanded by the student of plant diseases. The second paper is by Dr. B. B. Mundkur (*Trans.* **24**, Pts. 3 and 4, 312–36 ; Dec. 1940), and brings a crop of new species of smut fungi recorded from India. *Ustilago Polytocæ-barbatæ* was discovered in the Sipna Valley as long ago as 1908, but is now recognized as a different species from other smuts upon the same host. *Tilletia Panici* was found on Panicum grass at Calcutta, and is different from the four species previously recorded on this host genus. *T. Taiana* is new, and also *Ustilago Neyraudiæ*, *U. Lachrymæ-Jobi* and *U. Euphorbiæ*. *Doassansiopsis Martianoffiana* is not a new species, but is of interest for its somewhat unpromising habitat upon the floating leaves of Potamogeton. Full descriptions are given for each species, and several critical re-namings are suggested.

'Take-All' Fungus on Oats

'TAKE-ALL' disease of wheat, caused by the fungus *Ophiobolus graminis*, has not hitherto been regarded as a parasite of the oat. Growth of the latter crop was, in fact, regarded as one of the measures of control, for in practice, on 'take-all' infested land, the interposition of an oat crop had the same effect of starving out the fungus as had bare fallow. Elizabeth M. Turner has now discovered a variety of the fungus which can attack the oat crop (*Trans. Brit. Mycol. Soc.*, **24**, Pts. 3 and 4, 269–281 ; Dec. 1940). Isolates of the pathogen from oats grown in Wales were indistinguishable in cultural behaviour from *O. graminis* obtained normally from wheat, but inoculation experiments showed different powers of infection. Ascospores were also larger in the Cambrian material. It is proposed to regard the fungus on oats as a new variety, *Avenæ*, of *O. graminis*. Its appearance is disturbing, but it is possible that the very limited distribution will still allow the use of the oat crop as a practical means of control of the 'take-all' disease of wheat in most regions.

Photosynthesis

SOME experiments on the photosynthesis reaction in green plants have been made by S. Ruben, M. D. Kamen, W. Z. Hassid and L. H. Perry (*J. Amer. Chem. Soc.*, **62**, 3443, 3450, 3451 ; 1940), using the green alga *Chlorella pyrenoidosa* and carbon dioxide containing radioactive carbon formed by the bombardment of boron oxide by deuterons : ${}^{10}_{5}\mathrm{B} + {}^{2}_{1}\mathrm{D} = {}^{11}_{6}\mathrm{C} + {}^{1}_{0}n$, and present in air to the extent of 1 to 5 per cent. It was found that carbon dioxide uptake occurs also in the dark at a rate independent of the chlorophyll concentration but related to the capacity for carrying out photosynthesis, indicating that it is a primary step in the process. Special experiments eliminated reduction of ${}^{11}CO_2$ by exchange reactions. Light and dark CO_2 reductions show the same sensitivity as normal photosynthesis to the action of inhibitors such as HCN. The chemical identity of the radioactive compounds formed in the dark is unknown, but the presence of at least one hydroxyl and one carboxyl group in the active molecules was established. Most of the ${}^{11}CO_2$ taken up in the dark was found in the carboxyl groups ; in the light a smaller but appreciable fraction was in the carboxyl groups. No radioactive carbon was found in formaldehyde or other volatile substances, even after very short exposures. Sedimentation velocities of the radioactive molecules formed indicate that their molecular weight is about four times that of sucrose. In a tentative mechanism it is supposed that RCOOH formed in the dark from RH and CO_2 is reduced to RCH_2OH in the light : $RCOOH + H_2O = RCH_2OH + O_2$, and this takes on another CO_2 molecule, and so on until a long chain is built up. The COOH group so formed is not active, as it can be formed by exposure to inactive CO_2. It is suggested that the primary photosynthetic process is not the formation of a CO_2-chlorophyll complex but the conversion of CO_2 to CO-OH on a large molecule, the subsequent photochemical reductions not producing formaldehyde. The scheme is correlated with the energy requirements for the various reactions.

Evolution of the Atmosphere

IT is known on geochemical grounds that, in all probability, the primitive atmosphere contained no free oxygen. J. H. J. Poole has, in a recent paper (*Sci. Proc. Roy. Dublin Society*, **22**, No. 36 ; Feb. 1941), considered its probable constitution in the light of the data supplied by the average composition of the igneous and sedimentary rocks of the lithosphere and estimates of the total mass of igneous rocks denuded during geological time. From these it would seem that the free carbon now present in the sediments could not all have been derived from the carbon dioxide in the primitive atmosphere. This may have contained large quantities of methane, but there are grave objections to this view. The original liberation of free oxygen is attributed to the photodissociation of water vapour in the upper atmosphere, followed by the gradual escape of hydrogen, rendered possible by the high temperature probably occurring in this region. This might cause the accumulation of sufficient oxygen to allow plant life to start, and then produce by photosynthetic decomposition of carbon dioxide the main part of the oxygen which is present to-day, or has been used up in the formation of the sedimentary rocks. The author considers quantitatively the various problems involved in this theory, and shows that the original accumulation of free oxygen would have been a slow process. This view agrees with the fact that there is no evidence to show that life existed on the earth during, at least, the first half of the age of the ocean. After a brief discussion of the apparent absence of both oxygen and water vapour from the outer atmosphere of Venus, the author concludes by pointing out that in the present state of our knowledge the views advanced in the paper must be regarded as highly speculative.

Aluminium and Lithium Borohydrides

H. I. Schlesinger, R. T. Sanderson and A. B. Burg (*J. Amer. Chem. Soc.*, **62**, 3421 ; 1940) have examined the properties of the compound AlB_3H_{12}, obtained by the action of aluminium trimethyl on diborane : $Al_2(CH_3)_6 + 4\,B_2H_6 = 2B(CH_3)_3 + 2AlB_3H_{12}$. It forms colourless crystals, m.pt. −64·5°, b.pt. (extrapolated) 44·5°, is a non-polar compound, and in its chemical properties resembles diborane, reacting vigorously with oxygen, water and hydrogen chloride, and forming addition products with equimolecular amounts of dimethyl ether and trimethylamine, which compounds undergo complex reactions on heating. AlB_3H_{12} reacts with lithium ethyl to form $LiBH_4$ and evidence of the existence of BeB_2H_8 was obtained. The aluminium compound may be formulated as $Al(BH_4)_3$. Electron diffraction measurements with AlB_3H_{12} (J. Y. Beach and S. H. Bauer, *J. Amer. Chem. Soc.*, **62**, 3440 ; 1940) lead to a possible configuration and interatomic distances. The Al atom is linked to three BH_4 groups at angles of 120°, the molecule being planar except for the hydrogens. The boron atoms are located near the centre of trigonal bipyramids formed by the four H atoms of each BH_4 group and the central Al, and the interatomic distances are Al-B $2{\cdot}14 \pm 0{\cdot}02$ A., B-H $1{\cdot}27 \pm 0{\cdot}04$ A. The electronic configuration of the molecule is discussed on the basis of a number of structures in resonance. The preparation and properties of lithium borohydride $LiBH_4$ are also described (H. I. Schlesinger and H. C. Brown, *J. Amer. Chem. Soc.*, **62**, 3429 ; 1940). It differs from the aluminium and beryllium compounds in not furnishing borine trimethylammine, $H_3B : N(CH_3)_3$, with trimethylamine. LiB_4H_2 melts at 275° and decomposes at the same temperature. A salt-like structure $Li^+BH^-_4$ is suggested.

SHEEP TICK AND SHEEP MAGGOT PROBLEMS IN GREAT BRITAIN*

THE sheep tick, *Ixodes ricinus* L., in the British Isles is confined principally to the uncultivated regions, the hills and moorlands, the wooded districts or areas of peat bog. It is responsible for the transmission of louping ill and tick-borne fever in sheep and for widespread pyæmic infections in young lambs. The losses in sheep stock may be very severe if the flock has not been acclimatized to these diseases. Death-rates of upwards of 50 per cent have been recorded in the first year of exposure to infestation by disease-infected ticks.

The tick can live on a variety of hosts, and experiment has shown that it can survive as a species in the absence of sheep. The physical factors controlling its distribution have been shown to be moisture during the summer and possibly temperature during severe winters. The conditions of high humidity in the summer and protection from black frosts in the winter are only to be found in rough pastures over peaty or acid soils where there is a layer of moss and rank or old vegetation; that is, precisely those vast expanses of wild moorland and hill the reclamation of which is out of the question. The protection of the sheep by chemical means has therefore been the main line of attack.

Over the greater part of Britain the tick has two seasons of activity; it appears in large numbers on sheep in spring and early summer, and to a less extent in the autumn. Provided sheep can be protected during these periods, they may be allowed to graze over infested pastures without precautions during the rest of the year.

Sodium arsenite (0·2 per cent arsenious oxide) has been shown to continue to kill adult female ticks attaching to sheep for a period of 10–14 days. Derris, at a concentration of 0·02 per cent resin, has a similar effective duration. The addition of wool grease enhances the effective duration of arsenic but not of derris. Based on these findings, a protective dip has been evolved which gives protection of a high order during the first week or ten days, when the ticks are killed by the derris before they can attach. Afterwards the protective effect is due to the arsenic, which kills the females after they attach. For this dip an immersion period of at least half a minute is necessary. The dip is suitable for dipping sheep generally, but in particular it is useful for the dipping of lambing flocks. It is advocated that one dip be given immediately prior to lambing and another after about three weeks. For lambs a derris dust is used; this was suggested by Mr. Lyle Stewart of King's College, Newcastle, and it has been tested out on a large scale by him. It gives satisfactory protection for about a fortnight. The harmlessness of derris (except as a fish poison) makes it a useful substance for frequent dipping of sheep where it is desired to reduce a tick infestation by using sheep as trap animals.

The losses due to sheep maggots can be classed under two main heads: the direct loss of meat caused by death or loss of condition; the indirect loss due to the labour involved in looking for and cleaning up infested or dirty sheep. The chief culprit in Britain is the 'green-bottle', *Lucilia sericata* Mg., but recent work has shown that other blowflies attack sheep in certain circumstances.

Before maggots can develop on sheep, two conditions are necessary: (1) the fly must be attracted to lay in the fleece; (2) the environment must be suitable for the development of the eggs and larvæ. Various putrefying materials attract *L. sericata* to oviposit on live sheep in the field; also, ammonium carbonate, indole or skatol, all typical products of putrefaction. These materials only attract gravid females of *L. sericata*, and they are only effective in conjunction with live sheep, which supply a second essential factor. The limiting factor for the growth of maggots in the fleece is moisture. At the temperature of the sheep's skin, blow-fly eggs and larvæ cannot survive unless the humidity approaches saturation. The relative humidity of the basal fleece air is normally too low for the establishment of myiasis; it is below 50 per cent in dry weather and seldom exceeds 70 per cent after rain.

The majority of strikes occur in the tail region, as wool soiled with loose dung or urine supplies the conditions necessary for maggots. However, strike is quite common in clean wool on the back, where moist conditions may be due to penetration of the fleece by rain or excessive secretion by the skin glands. One method of control is the prevention of the development of a susceptible area. 'Crutching' is a simple method of preventing strike in the tail region. This consists of shearing the wool away from the area around the tail so that this part keeps clean. Crutching is an established method in Australia and has given good results in experiments in North Wales; it keeps the sheep clean and free from maggots for about four weeks until the wool grows again. Unfortunately, there is a great deal of prejudice against the method on account of its effect on the appearance of the sheep.

Advances in chemical control have been made possible by this work on susceptibility, repellents being tested by making sheep attractive with indole, larvicides by an experimental method of producing myiasis (by placing eggs or young larvæ under a pad of moist cotton, wool in the fleece). As maggot flies are strongly attracted to sheep, repellents have only a limited value. The fly dips in most general use are arsenical mixtures which act mainly through larvicidal action. For preventing maggots, it is the arsenic close to the skin which is effective, and this soon becomes reduced in amount, not by leaching with rain, but by the growth of new wool. Calomel has recently been found to be a promising material for preventing maggot infestation; it acts against the egg stage, the active principle being apparently mercury vapour. Calomel may be too expensive for dipping purposes, but should prove useful as an ingredient of preventive dusts and maggot dressings.

---

* An article based on the following papers read at the annual general meeting of the Association of Applied Biologists on February 14, 1941.

"Recent work on the Sheep Tick and its bearing on control Measures", by Dr. J. McLeod.

"Recent work on the Sheep Maggot problem", by Dr. R. P. Hobson.

"Some practical aspects of the Sheep Blowfly Problem", by Dr. I. Thomas.

The presence of dung and urine in the dip may seriously impair its protective action. Suint, the water-soluble fraction of the fleece, is a further contaminant which may be more important. Suint contains a large proportion of soap; this dissolves in the dipping fluid and completely changes its physical properties, the surface tension falling appreciably. When much suint has accumulated in the dip, the retention of arsenic by the fleece is reduced and the immunity to artificial maggot infestation is decreased; these observations may explain the poor results often obtained when large numbers of sheep are dipped without changing the bath.

With regard to the treatment of infested sheep, further information is required about the breeding habits of the fly. If the sheep blow-fly population is derived mainly from live sheep, and not from carrion, then the first essential of a good dressing is the killing of maggots. It should also promote rapid healing and protect the wound against re-infestation.

In a problem of this nature there are two main avenues of attack: the host might be made immune or very resistant, or the pest might be greatly reduced or exterminated. Work in Britain has been concentrated mainly on chemical means of protecting the host by the use of dips. Jetting has been tried in Scotland, but protective dusts have not been experimented with on a large scale. The control measures at present available to the farmer are dipping and crutching. Indirectly, the prevention of scouring in sheep by good shepherding and the use of anthelminthics, is important.

Our knowledge regarding the ecology of the sheep blowfly in Britain lags very much behind the biochemical work on the maggots and the susceptibility of the host. We know practically nothing about sheep blowfly populations or the ecological factors governing them. Perhaps the most pressing need is for knowledge of carrion-infesting flies, in particular the question of competition. Important practical recommendations resulted from such a study in Australia.

This unsatisfactory position is considered to be due to the facts that: (1) the farmer, not realizing how serious are the losses caused by sheep blowfly, has not pressed for control measures; (2) the subject is not one normally dealt with by either the veterinary investigation officer or the advisory entomologist; (3) money for this ecological work has not been available; (4) failure adequately to carry the results of present research over to the farmer.

THE CAMPBELTOWN RAISED BEACH AND ITS CONTAINED STONE INDUSTRY*

BY DR. W. J. MCCALLIEN AND A. D. LACAILLE

THE flint implements of Campbeltown are well known. The original discovery was made in the deposits of the so-called 25-ft. raised beach by a local naturalist, Alexander Gray, in 1894. The Abbé H. Breuil described and discussed them in his classic paper, "The Pre-Neolithic Industries of Scotland" (*Proc. Soc. Ant. Scot.*, **56**, 261–81; 1921–22).

As many diverging views have since been expressed on these artefacts, excavations were recently undertaken to determine their stratigraphical situation and cultural age, a site in the post-glacial raised beach, some 35 ft. above ordnance datum, near the Albyn Distillery, Campbeltown, being selected for exploration. The work yielded 1,235 objects attesting man's attention. Of these 724 were definable artefacts, 559 being of flint (the raw material imported from Ireland), 157 of quartz and 8 of schistose grit. Many are heat-crackled, a feature commonest among the waste which indicates their derivation from an occupation-site. The conditions of discovery are generally similar to those of previous finds in that the artefacts were found distributed throughout the upper part of the beach deposits, although locally they were concentrated.

The components of the Campbeltown stone industries constitute the earliest evidence of the colonization of this part of Scotland. Originating from sites occupied on the shore during the time of rising sea-level in the early post-glacial period, they were incorporated into the beach formation during the emergence which followed.

The present study now enables us to determine a closer connexion between the industries of the equivalent raised beach on the Scottish and Irish sides of the North Channel. The Upper Palæolithic tradition so often stressed as being strong in the Argyll beach industry is not the only influence which left a mark on the stone products of the settlers. A faint Azilian strain appears in some steep round scrapers, while Tardenoisian influence is manifested by some artefacts, including that significant cultural index the micro-burin. The infiltration of Baltic Forest Culture is also suggested by a few objects, a small pick being particularly significant. On the other hand, some tool-forms, such as the "Larne pick", previously unknown outside Ireland are now seen to have a place in Scotland.

This new Campbeltown series of implements, belonging to what is essentially a fine blade industry, compares strictly with those of the Antrim beach assignable to the Early Atlantic climatic period and to Early Mesolithic culture. The Campbeltown industry is equated with Movius's Horizon 2 (Early Larnian) at Cushendun (*Proc. Roy. Irish Acad.*, **46**, C.I., 1–84; 1940). The Campbeltown group, however, including gravers, micro-burins, trimmed and obliquely truncated flakes abruptly retouched, and a pick, is more comprehensive and advanced culturally than its close counterpart across the North Channel.

The conclusion is reached that (*a*) from various pre-Neolithic elements the beach people developed a provincial culture of their own, (*b*) Tardenoisian methods of implement manufacture had reached

---

*Summary of a paper read to the Society of Antiquaries of Scotland on February 22.

Scotland earlier than was thought, and (*c*) the influence of Baltic Forest Culture was more widespread in Scotland, both in geographical distribution and duration in time than has generally been held to be the case.

So far, only the more complex Antrim raised beach provides evidence of the evolution of the lithic element in the pre-Neolithic culture which flourished on the shores of south-western Scotland and north-eastern Ireland, but there exist indications to suggest that future inquiries in Scotland will afford analogies. The Campbeltown Early Mesolithic industry must antedate the advanced bone and antler industries from the Argyll shell-mounds and caves, the situation of which points to occupation during Late Atlantic times following the maximum submergence. This is possibly equatable with the Littorina transgression of the Baltic. In Baltic chronology, which cannot yet be applied with certainty to Scotland, the period of the Littorina raised beach may be taken as 5000–2500 B.C., the maximum transgression in Denmark taking place about 4500 B.C.

EARLY MATERIA MEDICA CABINETS

As a quiet and pleasing relief from topics bearing upon the War, Mr. E. Saville Peck took as the subject of his lecture at the February scientific meeting of the Pharmaceutical Society "Three Early Materia Medica Cabinets in Cambridge".

The collections described, namely, those of J. P. Vigani, John Addenbrooke and William Heberden are of special interest for various reasons, but notably because they mark the time when the atmosphere of indifference to medical teaching which had hitherto prevailed at Cambridge began to be dispelled. Vigani, a native of Verona, who had taught chemistry in Cambridge for twenty years, was invested with the title of professor of chemistry in 1703, and it would seem that a chest containing more than six hundred specimens of materia medica, which was found in 1922 under the staircase of the library of Queens' College, was the one from which he lectured.

Mr. Peck has told, on a previous occasion, of the evidence on which he based his belief, and his description of the contents of the chest, which was published some years ago, forms a useful addition to the literature of drugs.

John Addenbrooke's chest, now in St. Catherine's Library, contains, besides the drugs, many geological specimens which he collected and labelled when in his undergraduate days he used "to range the circumjacent country, Cherryhinton, Grantchester and Trumpington and searched the chalk pits and moors for fossils and simples". The chest itself is made of deal and is much the same in shape as a flat-topped writing desk of the present day, having a frog hole in the middle, drawers all the way down and also at the back of the recess; each drawer is divided by wooden partitions into compartments of about 3 inches square. There are about twenty such drawers containing a fine collection of materia medica. Perhaps the best of these collections are the drawers containing gums, resins and the like, the drawer of roots and rhizomes and another containing barks and woods, and still another filled with seeds. Some of these specimens were labelled by Addenbrooke himself.

Incidentally, there is a fine specimen of coffee berries in Addenbrooke's chest; this "drug" had but recently been introduced, and a few years earlier, in 1680, had been described as being "most useless, since it serves neither for nourishment nor debauchery". Among other drugs introduced in the seventeenth century and specimens of which Addenbrooke collected, were jalap, serpentaria, calumba and balsam of Tolu.

The third chest described by Mr. Peck was that of William Heberden, who was admitted a sizar of St. John's in 1724, and was made a medical fellow in 1734, proceeding to the degree of M.D. in 1739. He gave an annual course of lectures in materia medica, and made good use of his knowledge of the classics to adorn them; the collection of materia medica which he had formed to illustrate his lectures he presented to his college when he left Cambridge to practise in London, where among his patients was Dr. Johnson. Boswell relates that when he was asked what physician he had sent for, he replied, "Dr. Heberden, ultimum Romanorum".

Heberden's cabinet is made of oak and contains in the upper portion twenty-eight drawers and below a cupboard with two shelves. The contents are noted in a manuscript catalogue of July 10, 1751. The three cabinets described have many points of similarity; all three contain almost identical substances, most of which are mentioned in Culpeper's Herbal and the London Pharmacopœia of the time. They are contained in little paper trays folded in similar fashion and placed in the various positions in the drawers.

Cambridge is fortunate in possessing such treasures and, as Mr. Peck acknowledged, pharmacists are grateful to the Colleges for the care they have taken of them for more than two centuries.

RECOGNITION OF COLOURED LIGHT SIGNALS

A PAPER was read to the Illuminating Engineering Society on February 11 by J. G. Holmes on the recognition of coloured light signals. The apparatus described in the first part of the paper was made to provide a spot of coloured light suitable for observation under conditions comparable with night signalling, and capable of variation through a wide range of colours, the energy distributions of which were similar to those of the usual signalling colours.

The apparatus is similar to the Donaldson colorimeter, but with eleven primaries. Eleven beams of light from a common light source pass through coloured filters and through adjustable apertures, before being mixed in an integrator, and any required colour is obtained by combining the appropriate amounts of the three nearest primary beams. The range of colours covers the spectrum from extreme red to emerald green (550 mm.) and the area enclosed by this spectrum, and turquoise, royal blue, and purple with provision for particular consideration of white and yellow. The calibration was done with great care with a view of eliminating relative error between similar colours and to allow of statistical examination of results.

The test colours were obtained by the use of stencils selecting the primary beams, which gave 256 points on the colour chart, all being of the same luminous intensity and brightness, and each having a closely similar energy distribution to that which would be given by the corresponding colour filter, and would be used in practice.

The method of experiment was to show the 256 colours in random succession to an observer who was asked to give one of the simple names, red, yellow, green, blue, purple or white—to each test colour. This experiment was repeated for fifty observers, all of normal colour vision, and thus the number of times that any particular colour was given a particular name was found. Contours were then drawn on the colour chart showing the percentage frequency with which those simple names occurred over the whole area covered by the apparatus. A diagram is given showing the distribution of the names 'red' and 'green' for an illumination of 10 sea-mile candles at the observer. The experiment was further repeated with six observers selected to give average results, each making three observations at four different illumination levels, and with several different choices of names such as red, green, or white, and red, yellow, green or white and so on, and contours were drawn for each set of conditions. Experiments were carried out on the effect of a comparison light, light adaptation, and presbyopic vision, and altogether some 43,000 observations have been analysed and are represented in the diagrams.

The results are difficult to summarize, as the experiments were intended as a contribution to knowledge of colour recognition rather than a complete statement of the distribution of colour names. Red is the ideal signalling colour, being easily produced and yet recognized down to the lowest illuminations, even when not fully saturated. Green is satisfactory under usual conditions, but must be considerably restricted if blue is also used for signalling. Blue and purple cannot be regarded as satisfactory, the former requiring very high intensity and the latter depending on the dichromatic aberrations in the eye. Yellow and white are satisfactory if used separately, but they cannot be used together unless the white approximates to daylight.

It may be noted that whereas yellow has often been thought unsatisfactory, because of the confusion with white, the case is really that many whites are unsatisfactory because they are themselves too yellow. No significant difference was found between monochromatic sodium light and the equivalent lamp and filter combination. Presbyopic vision and light adaptation both assisted the recognition of blue and purple signals.

The paper concludes with a calculation of the optimum transmission factor for green colour filters based on the results obtained, and gives results which are reasonably consistent with those adopted in practice.

FORTHCOMING EVENTS

(Meeting marked with an asterisk is open to the public.)

Monday, April 7

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 5 p.m.—Mr. W. E. Doran: "The Ouse Drainage Problem".

Tuesday, April 8

CHADWICK PUBLIC LECTURE (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 2.30 p.m.—"Air Raid Shelters—Design and Construction, with special reference to Hygienic Considerations" (Dr. S. L. Wright: "Hygienic Considerations"; Mr. Phillip O. Reece: "Design and Construction").*

ILLUMINATING ENGINEERING SOCIETY (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 2.30 p.m.—Dr. J. W. T. Walsh: "The Measurement or Gauging of Low Values of Illumination and Brightness"; Mr. J. S. Dow: "Visibility by White and Coloured Light".

Wednesday, April 9

SOCIETY OF CHEMICAL INDUSTRY (at British Medical Association House, Tavistock Square, London, W.C.1), at 11 a.m.—Discussion on "Vegetables as Food".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

WOMAN GRADUATE IN PHYSICS—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham (April 9).

PRINCIPAL OF THE CHISWICK POLYTECHNIC—The Secretary (T), Middlesex Education Committee, Acton County School, Gunnersbury Lane, London, W.3 (April 16).

PRINCIPAL OF THE ENFIELD TECHNICAL COLLEGE—The Secretary (T), Middlesex Education Committee, Acton County School, Gunnersbury Lane, London, W.3 (April 16).

PRINCIPAL OF THE TOTTENHAM TECHNICAL COLLEGE—The Secretary (T), Middlesex Education Committee, Acton County School, Gunnersbury Lane, London, W.3 (April 16).

PRINCIPAL OF LURGAN TECHNICAL INSTITUTE—Mr. H. O. Armstrong, Technical Institute, Lurgan, Co. Armagh (April 21).

TEACHER (MAN) OF ENGINEERING AND MATHEMATICS at the Grimsby Technical College—The Director of Education, Education Offices, Eleanor Street, Grimsby (April 30).

TEACHER OF MINING AND ENGINEERING SUBJECTS—The Principal, Technical Institute, Canterbury.

PROFESSOR OF PATHOLOGY and a PROFESSOR OF PHYSIOLOGY—The Secretary, University College, Cork.

ENGINEER for the Public Works Department of the Government of Sierra Leone—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1 (quoting M/9552).

ASPECTS OF RECONSTRUCTION—II

A SPECIAL committee of the Town Planning Institute has been investigating the problem of compensation and betterment in relation to town planning*. A review of existing legislation on compensation and betterment and the acquisition of land by public authorities, including a survey of foreign practice, satisfied the Committee that essential planning, and particularly replanning, cannot be carried out effectively under the existing legislation; nor under any development of a system which involves the separate assessment of compensation and betterment in respect to each individual interest.

This Committee does not find that existing legislation is, in general, unjust to either private or public interests, although it recommends certain amendments which should mitigate some existing anomalies. The chief obstacle to the achievement of positive results by statutory planning is the multiplicity and variety of interests that hamper it on all sides, each of which has to be separately valued and taken into account. Consequently, where private ownerships present an obstacle to securing planned development, redevelopment or conservation on an economical basis, essential simplification and equity are likely to be best achieved by the wholesale purchase of areas by planning authorities. To facilitate this, the Committee recommends an amendment to the Town and Country Planning Act, giving powers to authorities to buy land required "for securing the preservation of existing buildings or other objects of architectural, historic or artistic interest or for the protection or improvement of agriculture". It is pointed out how essential it is that all publicly owned land should be subject to planning control under town and country planning schemes, and recommends that all land in the country should be planned and valued by one authority, on uniform principles and at one time, at intervals, for example, of five years, thus affording a datum time for the assessment of compensation or betterment.

These recommendations, the Committee considers, would secure rural preservation on a sound and fair economic basis, and check extravagant claims for schemes for the redevelopment of developed areas. It urges that creation of a National Planning Board with vested interests in development rights would be fatal, unless such rights were subject to planning control. It also recommends that land developers should be required, without compensation, to allocate not more than 35 per cent of the land for streets and open spaces, or instead to make a cash payment, such money to be used by the planning authority to provide open spaces in or adjacent to the land.

The Committee considers that mineral working is at present amply protected by the Town and Country Planning Act, but it strongly recommends that the owner should not be allowed to have the best of both worlds, but should be required to choose between mineral value and building value. It also proposes an amendment to secure that when surface minerals have been exploited no building value shall attach to the land, which will in consequence be available for open-space uses or for agriculture or afforestation at a value which makes such uses possible. It recommends the abolition of the disparity between compensation and betterment, and urges that the problem of the future will be to cope with the migration of population, not with its increase. The foundation of satellite towns would involve the occupation of compact areas of rural land, but in that case enough land should be purchased for the town and its agricultural belt, so that the question of claims for betterment would not arise.

---

* Town and Country Planning: Compensation and Betterment. Pp. 60. (Town Planning Institute, 11 Arundel Street, London, W.C.2).

The announcement that the Ministry of Works and Building has already set up an expert committee under Mr. Justice Uthwatt to examine the question of compensation and the recovery of betterment indicates that Lord Reith is already taking steps to deal with these problems. There is, in fact, already a wealth of material available for the assistance of the Minister of Works and Building, but even the most urgent demands for rebuilding require study and must conform to some plan if opportunities are not to be lost and fresh obstacles placed in the way of building more fitting and dignified cities where destruction has been concentrated. Unless at least the principles and outlines of an adequate plan are rapidly determined, there is grave danger that the necessity of physical rebuilding may in places jeopardize local if not national plans.

Scarcely less urgent are the second broad group of problems of reconstruction—what may be termed the rehabilitation problems. We shall be faced with the demobilization of large numbers of those in the armed and auxiliary forces and their return to peace-time employments. Industries that have swollen during the War to gigantic proportions will require relief from the troubles that may follow from surplus capacity. There will be other industries, which have had to close down during the War, to be restored to profitability. It would be optimistic indeed to assume that there will not be a new crop of depressed industries requiring care. Only foresight and careful investigation now can avoid severe dislocation and hardship when we begin to make the change-over from war to peace production.

There is no reason to be unduly pessimistic about our ability to surmount the difficulties with more success than last time, if forethought is given to the problems. The decline in our export trade, for example, which was such a stubborn element in our economic readjustment after 1918, is unlikely, in view of the much smaller part of export in our total economy to-day, to have the same effect on our general prosperity, even if it suffers as much. Moreover, we have advanced further in control of the trade cycle than we had in 1919. If we have a plan of campaign, we have a chance to control the post-War slump.

Overlapping with the remobilization of all our energies for the purposes of peaceful progress and orderly development are the problems involved in developing a new economic order and eliminating the frustration which has been responsible for the conditions leading up to the War, and removing the weaknesses which war has revealed. The development of our educational system and social services, the intensification of the attack on malnutrition and disease, the elimination of ugliness in our towns and replacement of the hovels that remain by worthy homes, demand creative thought as well as courage and determination to overcome whatever obstacles prejudice, vested interests, shortsightedness or ignorance may put in the way.

Success of such a policy and measures involves the fearless acceptance of the lessons of the War. No community can be exposed to such a strain as modern warfare imposes without some weaknesses in structure or organization being exposed. Underlying the concern which has recently been expressed at the position of war-production is a growing realization of how completely unprepared for war our industry was, how grave a handicap we must always labour under if, after every war, we show such complete confidence in eternal peace. Whatever the size of the standing forces we find it advisable to maintain after the present War, we shall be blind indeed to the lessons of 1936–40 if we do not maintain an embryo of munition industries, capable of rapid expansion, if we do not give all our citizens a minimum of training in their war-time duties, and if we do not make certain that stocks of the essential materials, adequately protected, are always kept in Great Britain.

A further weakness which the War has revealed is the apparent failure to train up a sufficient supply of men of ability to lead the nation. The courage, skill and character of such sections of the nation as the pilots of the Royal Air Force suggest the question whether our peace-time social structure really takes the advantage it might of such men. The lack of ability at the top may be due to some defect or bottleneck in the system of selection, and our educational system must be overhauled from the social point of view to determine whether it is at fault not so much on the pedagogical as on the social side.

Along with educational policy and system, national industrial policy requires overhaul. We have slipped from a *laisser-faire* system into one of State-encouraged cartels, not from deliberate choice but in a fit of absentmindedness. The process has been accentuated during the War by the policy of selecting the controllers, and economic reconstruction will be impossible unless we first examine the system to determine whether it is united to achieve that combination of progress with security that should be the economic objective of a dynamic democracy. If we are on the wrong road, the demobilization of war-time controls will offer us our last chance to change course.

These are only some of the major questions which the stress and strain of war have brought before us and to which answers are being urgently demanded. There are many others—the wide field of building the nation's health, the readjustment of town and country life, especially for children, forced upon us by evacuation, and the new conception of colonial responsibilities to which the White Paper of a year ago gave expression. Here will be found the fields for Mr. Greenwood to plan in advance, as Mr. Churchill said in the recent debate, "a number of large practical steps which it is indispensable to take if our society is to move forward". The immensity of the task should be an inspiration and not a deterrent. The intensity of our concentration at the moment on the full utilization and proper distribution of the powers of production is providing us with the power to realize such plans when hostilities terminate. The expansion of industry dictated by the requirements of war is already, by the problems it creates, shaping the plan of future reconstruction. If that plan is worked out and set in motion, it will eventually, with the minimum of friction and delay, absorb the resources of production which will be released when the War comes to an end.

If therefore the call is to hard thinking and concrete planning, to the devising of appropriate machinery, drawing on the widest and wisest experience and ablest minds of the nation, it is equally one to co-operation. Mr. Churchill's plea for a continuance of national and political unity during the period immediately after the War is a sign that the Government is thinking ahead. Already it is becoming widely realized that the end of the War will be a signal, not to return to idleness and complacency, but to undertake great things. If that call is heeded, if professional men unite to bring a spirit of disinterested service, impartial inquiry and constructive thought into all those fields where their special knowledge or experience is of service, we need not despair of our ability to relieve distress and bridge the gap between war and peace, and to organize that full employment of resources which can both repair the ravages of war and usher in an ampler and nobler world order worthy of the sacrifices now being made.

RELATIONSHIP OF PURE AND APPLIED BIOLOGY

THE great number and the immediacy of applied biological problems in this time of war, coupled with the embarrassingly small use made of pure biologists by those in authority, has raised acutely the problem of the relationship of pure and applied biology*. To a certain extent academic botanists and zoologists are themselves to blame for their apparent uselessness, since for long they have tended to hold themselves aloof from applied work and have, indeed, sometimes decried not only its intellectual status but even its scientific value.

This superficial and arbitrary division of biology into 'pure' and 'applied' is a very unfortunate development of comparatively recent times. For Robert Boyle, true science was such knowledge "as hath a tendency to use", and for Francis Bacon "such philosophy as . . . shall be operative to the endowment and betterment of man's life". So recently as the days of Pasteur there was neither 'pure' nor 'applied'; there was simply biology, botanists and zoologists increasing knowledge and adding to the sum of human welfare. But in the thirty years or so overlapping the birth of this century, a series of trends and conditions, which in themselves make a fascinating history, led to the professionalization of biology; by the early 1900's most university professors had become 'pure' biologists, and by the 1920's they had become narrow specialists in one or another branch of pure biology. Such a condition was, clearly, far from satisfactory.

So artificial, so one-sided and extreme was this development, that it stimulated a reactive movement. In 1904 the Association of Applied Biologists was founded, and although of small numbers and living a somewhat precarious existence in its early years, it survived to become the focus of a great development of application and research. In 1914 it established the *Annals of Applied Biology*. In 1909 the Development Fund Act was passed, and during the next fifteen years practically the whole of our present organization for applied biological research and the application of biological knowledge came into being. But the enormous growth and the very success of this organization, its wide range and the scale of its activities, only accentuated the distinction between pure and applied biology. The pure workers, fearful lest these Goths and Vandals storm their scholastic defences, or even absorb them, tended to shut themselves up like beleaguered garrisons within their ivory towers, and to develop a specialized and self-justificatory life of their own remote from the moil and toil of common life. So, to-day, there are the pure biologists holding the academic posts, and the others, the applied biologists, holding posts ranging from research institutes to commercial firms. Research institutes may be attached to universities, but, even so, their staffs are often regarded as slightly tainted.

---

* Discussed at a joint meeting of the Association of Applied Biologists and the Society for Experimental Biology on Friday, March 28, 1941. The opening addresses were given by Prof. P. A. Buxton and Prof. W. B. Brierley. See also pp. 436 and 439 of this issue.

The whole gamut of appointments from research institutes to industry is, of course, staffed by men and women trained in the universities. But, unfortunately, this is a one-way traffic system, and only in the rarest cases is there appointment of men from the applied side to the university staffs. During the last ten years the number of men who have returned to the fold can almost be counted on one hand. So, again the credo of academic men is accentuated, that they are the fount and inspiration not only of all knowledge but also of all application. As, year by year, successive vintages of students are conditioned to this belief by their academic teachers, by their academic curricula, and by every academic influence in a most formative period of their lives, so this myth lives on, rarely questioned. Occasionally, a mouse-like squeak of dissent arises, but the state of academic auto-hypnosis is little disturbed. In this connexion, academic authorities might well consider overhauling their system of appointments committees. Too often, at any rate, in the case of biology, those appointed to consider applications for academic posts are out of the field of modern research and biological advancement and should not, therefore, be put in the all-important position of deciding the future policy of biological teaching and research through their choice of candidate. It would be a decided advantage if applied research, in the form of a biologist or biologists from an industrial or agricultural institute, were more fully represented on those committees appointed to settle appointments to senior academic positions.

Now the danger of this situation is that there is no reciprocal fertilization: applied biology receives stimulus and inspiration from research in pure biology, but the academic workers not only shut themselves off from any reverse stimulus and inspiration, but often actually seem to take pride in their isolation, a state of folly that the most casual reading of the history of science should expose. Yet their almost pathological fear of the tainting or even absorption of pure science by applied science colours their vision: they feel themselves to be crusaders defending the sanctity of pure science, which for them possesses almost a mystical quality.

The psychological motivations in this situation are fairly clear, but its immediate practical importance lies in its repercussions, the influence this situation must have on biology as a scientific discipline, on biology as a vocational training for teaching, for agriculture and horticulture, for industry and commerce, on biology as an avenue for the intellectual development of the individual, and on biology as a primary constructive factor in social life and the progress of civilization. What all biologists would deplore is that pure biology, defending its virginity, should lapse into barren spinsterhood.

A question very ripe for the asking is whether this dichotomy or antithesis of pure and applied biology serves any good purpose, or whether, recognizing its falsity, it is not imperative to attempt a reconstruction and unification of the science. Certainly if our scientific societies and our scientific journals were reconstructed and unified, we should all be very much better off financially, there would be an enormous saving of time and energy, and scientific publication and the professional organization of biology could be enormously improved. From the point of view of the research development of the subject the advantages of such a unification of the pure and applied aspects are obvious. Such a unification does not, of course, imply that the economic biologist should immediately investigate fundamental problems, or that the theoretical biologist should undertake a modicum of commercial practice. It does, however, imply, especially on the part of the pure biologist, very much more give and take, much more understanding and sympathy, and a greater exercise of imagination in his contacts with mother earth. It would, for example, be perfectly simple to arrange exchange appointments or periods of service between members of university staffs and those of research institutes, or one or another existing applied biological organization. The cross fertilizing influence of such interchange on both teaching and research would be immense.

It further implies that the academic curricula and system of training should not be regarded solely as a logical discipline, justified purely by intellectual criteria, but that attention should equally be given to biology as a factor in cultural and social life. A university degree in botany or zoology should not only be the hallmark of a competent botanist or zoologist, but it should also be the hallmark of an educated man, one capable of visualizing his biology not only as a logical system in a perspective of scientific values, but also as a means towards a fuller life in a more richly endowed social community. Pure science, guiding the student to a logical intellectualist ideal, leaves him facing the mental apparatus and not the concrete problems of life as life is lived in the world in his time. Biological teaching is only adequate when it brings biology into relation with everyday life. Biology for the biologist is totally objectionable ; biological results show their highest value by becoming the property of the people. Our traditional methods of biological education are, at best, too much occupied with intellectual analysis, at worst, too much occupied with the acquirement of formularized information ; we emphasize abstract formulations and neglect their wider human applications. Praiseworthy efforts to change this are now being made by the British Social Hygiene Council, especially through its Educational Advisory Board.

Applied biology is an integral part of the vital thought and culture of our age and, as such, must be incorporated in any constructive system of higher education. The way to accomplish this is not by the insertion of so many additional courses on the several aspects of applied biology into an already overladen curriculum : students already suffer not only from intellectual strabismus, but also from chronic mental indigestion. An infinitely better way, perhaps the only satisfactory way, is to effect a thorough reconstruction of our curricula, simplifying, condensing, and pruning, eliminating all the venerable accumulations, the merely traditionalist and sentimental moieties, the moribund and dead matter, the intellectual vested interests, the fetishes and shibboleths, exercising the most stringent selection, and balancing them throughout with a more luminous vision and a more prospective imagination. For more than a generation biological teaching has been strung along the threads of logical evolutionary principles, but it should be patterned as a fabric of which the warp is the principles of logic and the woof the humane relationships of biology.

It is usually objected that all biologists, but perhaps more especially those whose leaning is towards application, must be given "a sound fundamental training", and it is always assumed that this is given by our present system. Whether this system is the only one which can do this, whether, indeed, it is the best system for this purpose, is never raised in question. Now all biologists, pure and applied, will agree that in his training a student should attain certain values, and these values are what is usually implied when the phrase "sound fundamental training" is used. But are these values anything more than the acquirement of the scientific outlook and attitude, familiarity with scientific methodology and technique, knowledge of analytic data within a recognized field and capacity to evaluate such data, and appreciation of logical scientific principles with facility in their exemplification ? Does a "sound fundamental training" imply more than this and, if not, cannot these values be achieved better from biology presented as a unified and patterned fabric of development than from biology presented purely as a logical system in the traditionalist way ?

Life is wider than logic, and no scientific system is sufficient unto itself. We want our students to be not merely experts in some particular branch of science, but also experts in the art and understanding of life. The improvement of natural knowledge for use is a duty as instant as that of improving natural knowledge for discovery. Science is not merely a channel of escape to a private and self-sufficient world, to be justified by remote and abstract criteria ; science is a social function, with social roots and social consequences, and if our science, if biology, is to live on as a vital human force, it must ever keep essential human values in view, and it must justify its existence in the world by its contributions to it.

FERTILITY, GROWTH AND BREEDING OF FARM ANIMALS

Farm Animals:
their Breeding, Growth and Inheritance. By Dr. John Hammond. Pp. viii+199. (London: Edward Arnold and Co., 1940.) 14*s*. net.

AMONG the authors of recent texts on animal breeding, there are no armchair philosophers who, retiring from active research, have time to write a comprehensive and well-balanced treatment of the whole subject. In the distant future, it is to be hoped, Dr. Hammond will fill this rôle. Meanwhile he has provided a short account of his more immediate interests in the form of two series of lectures—the one on fertility and growth and the other on genetics in relation to the practical problems of breeding farm animals. Were it not for the second and shorter part, the contents might well be described as a résumé of recent Cambridge experiments on fertility and growth. Problems of fertility, artificial insemination and proportional growth in all the main classes of farm livestock have been discussed in the light of research which Dr. Hammond has himself carried out or inspired. The work on fertility has given promise of greater breeding efficiency, particularly in horses, which are notoriously unreliable. Besides a very clear and concise account of the ordinary processes of reproduction and the diagnosis of pregnancy, there are hints of future developments in hormone therapy. The possibilities with sheep in this direction are notable since they include raising, where desired, the numbers of lambs born, and extending the mating season. Closely linked with the subject of fertility, of course, is that of artificial insemination, the most effective use of which presupposes a thorough understanding of the natural process. No attempt has been made to advocate artificial insemination on a grand scale, but those whose special circumstances require it will find here much good practical instruction.

The economic pressure which has focused attention on the question of quality in meat will be familiar to most readers. Equally familiar no doubt will be the fruits of Dr. Hammond's efforts in this field. Here, in small compass, is developed the principle that changes in the proportions of the organs and tissues follow a definite course during growth. It is further shown that this course, and therefore carcass quality, can be modified by either raising or lowering the plane of nutrition. By implication, the right weight at which meat animals should be slaughtered and the appropriate rates of live-weight gain at various stages of growth can be determined. Just how much control can be usefully exercised without conflicting with other considerations, such as the periodic nature of the supply of certain feeding stuffs, or the varying response of different individuals to the same treatment, is unfortunately not yet clear. Rapid growth-rate up to weaning time, however, is usually desirable, and this is in line with the advantages of improving intra-uterine nutrition and milk production.

The second part of the book will interest geneticists because Dr. Hammond holds independent views on certain aspects of heredity. He suggests repeatedly, for example, that genes may be classified either as unit factors governing the appearance of fancy points or deleterious recessives, or as multiple factors which control variation in quantitative characters and tend to be dominant. The impression is given that mutations affect mainly the unit factors, and are nearly always worthless. Even the polled character is doubtful, since on p. 135 it is not mentioned as having any semblance of real economic value, whereas on p. 149 it is pointed out that there is a need for a polled Shorthorn breed to save a lot of time and money now spent on dehorning beef cattle. While no one is likely to deny that the bulk of obvious mutations are useless to the breeder of commercial stock, such a simple classification of genes will be questioned. Furthermore, it is very doubtful whether there are any basic distinctions yet to be drawn regarding their behaviour in mutation or development.

These innovations might have been more impressive if they had not been accompanied by a number of dubious examples of the workings of heredity. Hernia in pigs, for example, is conveniently assumed to be a simple recessive (p. 146) although it is by no means certain that multiple factors are not involved. Again, on p. 142, grey colour is referred to as dominant to bay in horses although the genes concerned are not alleles; on p. 171, the sire and dam together are said to contribute half the germplasm to the offspring instead of half each, thus confusing the conception of parent-offspring correlation; and on p. 150, five generations of backcrossing are regarded as sufficient to achieve the transfer of a single gene from one breed to another, which is an over-simplification. Such inaccuracies, like the rather plentiful printing errors, might be accounted for by limitations of time or space. But underlying the more substantial departures from current genetic theory has been the feeling that random mutations are inadequate to account for the progress in livestock breeding, although in respect of conformation that progress is shown to be actually a hastening of the tempo of evolutionary trends. The creation of improved environments is therefore supposed to have a directive influence on the mutation of genes affecting productive qualities (but not of unit factor genes)—which recalls Lyssenko's attitude.

Many readers will still feel disinclined to discard the more orthodox theory of evolution, even for farm animals, until forced to by weight of evidence. The further contention that selection, to be effective, should be practised under the most favourable environmental conditions, although widely supported, is often misleading. Selection *under* these conditions is selection *for* them. The unqualified idea that the resulting animals can then be used readymade elsewhere appeals, just as something for nothing always does. Yet surely they can be used successfully for grading up poorer stock only at a price which may be the preliminary grading up of the environment, lowered carrying capacity, or reduced hardiness.

Fundamentally, however, Dr. Hammond's philosophy is very wise. As fast as environment can be improved, animals able to make the best use of it should be bred. Unhappily, livestock improvement often lacks impetus and guidance, and awaits the establishment of some practical means of short-circuiting the wearisome piling up of performance records. To that end, Dr. Hammond has rendered great service by clarifying obscure problems, and giving more specific direction to breeding efforts.

H. P. DONALD.

METABOLISM OF INORGANIC SUBSTANCES

Mineral Metabolism

By Dr. Alfred T. Shohl. (American Chemical Society Monograph Series, No. 82.) Pp. x+384. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1939.) 30*s*. net.

THE excitement of the race to establish the formulæ of vitamins has diverted interest from other branches of the science of nutrition; but now that so many vitamins have been synthesized, attention is turning more and more to the study of the metabolism of inorganic substances. Many elements are essential for growth, and, in a number of cases, the quantities required are no larger than the quantities of vitamins required, but there are still many obvious gaps in our knowledge of their action. The experimental methods developed for the study of vitamins may be applied to the study of mineral metabolism, but the practical problems are different; the isolation of the active principle, so important in the case of vitamins, is no problem at all, and the main initial difficulty is to devise diets from which the active principle is absent.

The appearance of an authoritative monograph on mineral metabolism will be widely welcomed. It contains as much information per page as anyone could wish, but it is not merely a catalogue of results, nor a summary of the opinions of others. It is a balanced review of the work done up to 1938. The bibliography, which contains about 1,200 references, is not intended to be exhaustive, and may, in certain cases, cause irritation by failing to give due credit to the first discoverer of new facts, but it will certainly enable anyone to obtain access to the literature.

Successive chapters are devoted to the mineral composition of the body, secretions and excretions, internal secretions, total base, chloride, ammonium and bicarbonate, calcium and magnesium, phosphorus, sulphur, iron, iodine, traces, water metabolism, anion-cation relationships, and mineral intakes, balances and requirements.

The field is a wide one, and is not all covered with equal thoroughness. Potassium, for example, receives less attention than many would like to see accorded to it, while calcium and phosphorus are more fully discussed.

Everyone will find in this book much that is interesting and stimulating. Among the elements on which attention has been focused in recent years are bromine, manganese, silicon, copper and zinc, all of which are normal constituents of animal tissues. Bromine has been found in particularly high concentrations in the anterior lobe of the pituitary gland; deficiency is said to cause death in the second generation of rats. The view that chloride and bromide are interchangeable in metabolism is rejected. Deficiency of manganese causes effects not unlike those of deficiency of vitamin E; male rats lose the use of their testes, and female rats produce young which do not survive. Both copper and cobalt play an important part in the formation of red blood corpuscles. Dr. Shohl's conclusion that zinc is an essential element has, of course, since been confirmed and explained by the discovery of its presence in carbonic anhydrase; which will add to the interest of experiments on deficiency of this element.

The publication of this book will help to stimulate work in fields where there is still much to discover.

J. H. GADDUM.

SCIENCE AND THE NATIONAL EFFORT*

BY THE RIGHT HON. LORD HANKEY, P.C., G.C.B., G.C.M.G., G.C.V.O.

THE present position of scientific help in the prosecution of the War has been built up on foundations well and truly laid before war broke out, when the three great pillars of the permanent civil research organization of the Government were the Department of Scientific and Industrial Research, the Medical Research Council and the Agricultural Research Council.

Similarly, on the defence side there were important research organizations in the Admiralty; the Ministry of Supply, which undertakes most of the research work for the War Office; the Air Ministry, which, however, has now handed over most of its research work to the Ministry of Aircraft Production; and the Ministry of Home Security, which occupies a position intermediate between the Service Departments and the Civil Departments. In addition there was a good deal of research in the Civil Departments.

Just six months ago, with the approval of the Prime Minister, the late Mr. Neville Chamberlain, as Lord President of the Council, set up a Scientific Advisory Committee. It was the last official act of his long career. He had given much thought to the subject and when I last saw him he spoke of it with infectious enthusiasm: a characteristic instance of his far-sighted statesmanship. I am now drawing on my six months' experience as chairman of the new Committee. I had better begin by explaining its status. Besides the chairman, the Committee consists of Sir Henry Dale (the president of the Royal Society), Prof. A. V. Hill, M.P., and Prof. A. C. G. Egerton (joint secretaries of the Royal Society), together with the secretaries of the Department of Scientific and Industrial Research (Sir Edward Appleton), the Medical Research Council (Sir Edward Mellanby), and the Agricultural Research Council (Sir Edwin Butler, who unfortunately had to resign on grounds of ill-health); the chairman of the latter Council, however, Sir Thomas Middleton, has attended many of the Committee's meetings. In addition, at the request of the Committee, the Lord President of the Council invited Sir William Bragg, the former president of the Royal Society, whose term of office expired shortly after the formation of the Committee, to serve as an additional member until he had completed a period of twelve months. The joint secretaries are Prof. W. W. C. Topley, a distinguished fellow of the Royal Society, with a colleague from the offices of the War Cabinet.

The Committee is in touch through the Royal Society with the great streams of scientific research and development; through the representatives of Government research with Government activities; and through the chairman and the Lord President, to whom the Committee reports, with the policy of the Government in these matters.

The question has been raised whether in constituting this Committee the Government has interpreted the term 'scientist' too narrowly. The reason for not including representatives of applied science was not a failure to appreciate its great importance to our war effort, but simply that the proposal did not fit into the Government's conception of the Scientific Advisory Committee. The Government had envisaged a small body with contacts with the whole of science, but not representing any particular section, to ensure the utmost use of science and men of science in the prosecution of the War. The representation of applied science with its many branches must have involved some enlargement of the Committee and would have altered the whole plan. The Government, however, is at present in touch with the professional societies concerned with a view to the possible establishment of a separate organization working in the field of applied science and in close touch with the Scientific Advisory Committee, and an announcement may be expected before long.

The Committee has devoted itself mainly to the contribution of science in the war and will continue to do so. Nevertheless, the importance of the eventual use of science in problems of reconstruction has not been overlooked, and the Committee is in touch with the Minister without Portfolio, who is in charge of these matters.

At its first meeting the Committee decided to prepare as a background for future work a survey of the scientific activities of Government Departments.

In addition to obtaining written reports, the directors of scientific research of each of the Departments engaged mainly in war work were invited in turn to tell the Committee something of their activities. Sometimes they were accompanied by staff officers of the Fighting Services, as representing the users of research.

---

* From a statement before the House of Lords on April 2.

Owing to their secrecy, some of the subjects of discussion have to be confined to the smallest possible circle. To provide for this the Committee appointed a small Defence Services Panel composed of members who were already associated officially with secret Government research work.

In describing how far the assistance of men of science has been enlisted in the prosecution of the war, I shall return for a moment to what I called "the three great pillars of the permanent civil research organisations".

Thus the Department of Scientific and Industrial Research with its thirty-three advisory boards or committees, each dealing with a particular subject and each commanding the services of distinguished experts, disposes of a wealth of scientific talent. Their membership includes fifty-one fellows of the Royal Society. In addition, eleven members of the staff of the Department of Scientific and Industrial Research are fellows of the Royal Society. Eight fellows or university professors are retained as consultants, and fifteen university professors are engaged on extra-mural contracts in their own laboratories.

The ten Research Institutes for which the Department is responsible include the National Physical Laboratory, the Chemical Research Laboratory, and Laboratories or Stations for research on Building, Food Investigation, Fuel, Roads, Forest Products, Water Pollution and Pest Infestation. These, with the Geological Survey of Great Britain, provide facilities of immense importance to our war effort.

The Department renders assistance to the Fighting Services and to practically every Government Department; for example, in home security problems, such as building and shelter construction and bomb disposal, and to the Ministry of Food in food storage, by combating pests and devising economical methods of packing to save space. Geology, among other contributions to our war effort, has informed authorities as to where sand is to be found in urban areas, thus saving transportation and cost.

Similarly the Medical Research Council, with its forty-five committees or sub-committees, its National Institute for Medical Research, its nine smaller research units, and its connexions with research in universities and elsewhere, is doing much to help our war effort. For example, in concert with the Ministry of Health and other Departments concerned, preparations were made before, and expanded during the War, with the view of safeguarding public health against risks arising from war conditions, such as concentrations of transferred populations in some districts, to say nothing of the effects of enemy action. An Emergency Public Health Laboratory Service was established with laboratories all over the country so that any unusual outbreaks of disease might be rapidly identified. Stocks of anti-sera and vaccines were accumulated and distributed throughout the country.

In a speech in this House in July 1939, I mentioned that the application of research in nutrition usually lagged some fifteen years behind discovery. This is no longer true. Under pressure of war conditions results of research are being applied in many directions. The Food Policy Committee of the War Cabinet makes good use of a Scientific Advisory Committee, and the Ministry of Food has a technical advisory staff.

The sphere of the Medical Research Council extends far beyond 'medicine' as this term is generally understood. It is concerned in all problems that affect man's health and efficiency. This enables the Council to assist the Defence Departments in problems relating to personnel and the use of science for increasing the efficiency and well-being of the men who have to operate machines such as aircraft, tanks and so forth. Excellent work of this kind has been done by a Flying Personnel Research Committee set up by the Air Ministry with the co-operation of the Medical Research Council nine months before the War.

The Scientific Advisory Committee has brought this aspect of science to the attention of the other Service Departments. The scope of the Flying Personnel Research Committee has now been expanded to cover naval personnel problems and a Military Personnel Research Committee has also been set up.

The Agricultural Research Council, with its twenty-five standing and technical committees of men of science with special experience of the matters with which they are concerned, with its Field Experimental Station, and with its great influence on the work of the twenty-three existing agricultural research institutes and other agricultural research subsidized by the Government, also makes an important contribution to our war effort.

I come now to the use of science in the military side of the war, where, as already mentioned, the Departments concerned are—the Admiralty; the Ministry of Supply; the Ministry of Aircraft Production, and the Ministry of Home Security.

There is much in common between the methods of research and development of these Departments. Each has a director of research. The Ministry of Supply and the Ministry of Home Security have Central Advisory Committees to assist the directors in planning and carrying out the programme of work. The three Defence Departments are represented on them and the Committees include unofficial as well as official experts. The Ministry of Aircraft Production has an Aeronautical Research Committee, the successor of the Advisory Committee on Aeronautics established in 1909.

The First Lord of the Admiralty recently announced in another place that, in order to strengthen still further the co-operation between the Admiralty Research Department, outside scientific workers, and the Navy itself, the Board has decided to set up a Scientific Advisory Panel.

These Departments maintain research establishments, more than a score in number, all manned by highly qualified men of science. They work in close co-operation with one another, and one Defence Department will often refer a particular problem to an establishment maintained by another which has better facilities for the job. Each Department has frequent resort to the Department of Scientific and Industrial Research and the Medical Research Council, as well as to universities or other research institutes, or the research laboratories of producing firms. There is an increasing tendency to bring the large producing firms into co-operation at the earliest possible stage so that full advantage can be taken of their knowledge and experience.

I must also mention among Service research activities the Ordnance Board, which now acts under the Ministry of Supply. It is an interservice body with executive functions as to trials and calculations concerning fire-arms, their equipment, ammunition and armour. The Board derives originally from the Committee of Field Officers and Artillery under the ægis of the Board of Ordnance, 1518. Its standing members are officers of the three Services, and distinguished men of science are appointed from time to time as associate members.

Civil Departments may be divided for our purposes into those responsible for research establishments or for experiments or tests, and those which are not. Those Civil Departments which have no research establishments of their own usually have scientific committees, and both categories make wide use of the facilities of the Department of Scientific and Industrial Research, the Medical Research Council and/or the Agricultural Research Council.

The main conclusions of the Scientific Advisory Committee from its survey are that the scientific activities of the Government are far more extensive and far more effective than is commonly realized, and that much of the criticism is due to lack of knowledge of the facts. For example, one criticism is that the Government has failed to make effective use of the services of outside men of science. The Committee does not think this criticism justified. The names of nearly three hundred senior men of science associated in scientific work on behalf of the Government have come to its notice. This figure does not include the large numbers of younger men of science engaged continuously on war work in the numerous research establishments maintained by the Government, or in the Services.

It would be too much to claim that the fullest use is being made of every senior scientific worker, but in the more important fields the majority of those especially well fitted to assist our war effort have been given an opportunity to do so. In some fields, however, opportunities may not yet have appeared, and the Committee reports that there has been a feeling of frustration among individuals. In the case of junior scientific workers the demand in different fields of science varies and fluctuates so widely that it is impossible, except very gradually, to absorb in work of national importance all those who are anxious to employ their special knowledge in some form of war activity. Some help, however, is afforded by training schemes whereby men of science trained in one subject, where opportunities for war service are few, can be given rapid training in an allied science.

Having recorded general satisfaction with the range and effectiveness of the Government's scientific activities, the Committee comments that some of the existing forms of organization have proved more effective than others. It directs attention to the effective and economical methods developed by the Department of Scientific and Industrial Research and the Medical Research Council, the success of which it believes is largely due to the fact that they have been allowed full scientific freedom and complete control over the funds at their disposal.

The Agricultural Research Council, as at present organized, has not the same freedom of initiative and action. Believing the scientific development of agriculture to be of the greatest importance to the country, both during and after the War, the Scientific Advisory Committee has considered how much freedom might be secured, and the Council's activities thus made more effective. In consultation with the Minister of Agriculture and Fisheries and the Secretary of State for Scotland, the Committee has drawn up proposals for strengthening fundamental research and ensuring a more ready application of promising scientific discoveries to agricultural practice (see p. 447 of this issue).

So far as the scientific activities of the Defence Services are concerned, the points to which the Committee attaches the greatest importance are the following :

(1) Provision in the organization of departmental scientific staffs for regular consultation

with a strong advisory council or committee which includes outside scientific experts.

(2) The utmost possible use of the facilities of the Department of Scientific and Industrial Research and the Medical Research Council. This is already in operation and is likely to be extended.

(3) A much wider and more intensive study of those problems connected with early and adequate provision for the efficiency of personnel in the design of new instruments of war.

(4) The close co-operation at every stage of research, development and production between the operational and scientific staffs.

I come now to one or two other matters that have engaged the attention of the Scientific Advisory Committee.

The Committee has suggested the names of men of science for particular tasks or to assist in specific investigations to a number of Government Departments, as well as to the British Council. In this connexion I must mention the invaluable work of the Central Register of the Ministry of Labour and National Service, for the utilization in Government Departments and elsewhere of persons with scientific, technical, professional and higher administrative qualifications. With the aid of the Government Departments concerned, and of various outside organizations including the Royal Society, and of a very strong advisory council, the register is very comprehensive.

The question of enlisting scientific researchers of other countries and refugee aliens has been raised. The Scientific Advisory Committee has given a good deal of attention to this question. It presents obvious difficulties. If, as I have said, we have not absorbed into the Government war effort all our own men of science, we cannot absorb unlimited numbers of refugee men of science. In addition, much of the research work is so secret that precautions have to be taken. Nevertheless, a number of refugee specialists are employed in research laboratories, mainly on the medical side so far as the Government is concerned, but also in industry.

Scientific co-operation with the Dominions, India and the Colonies is satisfactorily provided for. Canada, of course, occupies a position of special importance, and her collaboration in the scientific field is proving of the greatest value. There is also in Canada scope for close co-operation in scientific matters with the United States. Prof. R. H. Fowler has been in Canada for some eight months, and is now being relieved by Sir Lawrence Bragg—a colleague of equal distinction.

The Committee has also taken a deep interest in the question of co-operation in scientific matters with the United States. At an early meeting it discussed the matter with Prof. John Fulton of Yale University, who was on a visit to Great Britain on behalf of the U.S. National Research Council. A member of the Committee, Prof. A. V. Hill, had already been to the United States on a scientific liaison mission, and the Committee had discussions both with him and with Sir Henry Tizard, on his return from a similar mission.

After consideration of the Committee's proposals, and after consultations with the proper authorities in the United States, a comprehensive scheme has been put in operation.

His Majesty's Government has elected and sent Dr. C. G. Darwin, the director of the National Physical Laboratory, as director of a Central Scientific Office working under the direction of the British Supply Council in North America to collaborate with United States research bodies, to act as a channel for exchange with the appropriate United States authorities of technical and scientific information, and generally to co-ordinate scientific and technical inquiries to and from the United States authorities, except on those Service questions that are dealt with through the Service attachés. The scientific mission to Canada is closely linked with this system so as to ensure a complete interchange of scientific and technical information between the three countries.

At the same time President Roosevelt has sent to Great Britain Dr. J. B. Conant, president of Harvard University, to establish a corresponding mission in this country, and Dr. Conant and some of his colleagues have attended meetings of the Committee. This mission has received a very warm welcome, and arrangements have been made to facilitate its work. Its permanent secretary, Dr Hovde, knows his way well here, for, as a Rhodes Scholar, he spent some years at Oxford. Accredited American men of science have already arrived in Great Britain.

The historians of war from the earliest time pay their tributes to the importance of science. The theme of a long chapter by Polybius on Archimedes is that "The genius of one man is more effective than any number whatsoever". In these days no one man, whatever his genius, can cover more than a fraction of the immense field of science in war, of which I have only been able to give the faintest impression in the time at my disposal. We require thousands of scientific workers.

We are engaged in a death struggle with an enemy who boasts, with justification, of his achievements in the field of science. Our men of science are at least as good as his, and with the aid of the scientific resources of the Empire, and especially of the Unites States, we are building a scientific equipment which is destined to play an ever-increasing part in our war effort and in the period of reconstruction that must come thereafter.

MALARIA IN WAR*

By DR. V. B. WIGGLESWORTH, F.R.S.
LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

THROUGHOUT the centuries of European history, from causes that are still subject to dispute, malaria has ebbed and flowed like a fatal tide[1]. During the nineteenth century the disease was in retreat and in 1914 seemed to be hanging on in only a few localities, mostly in the south-east corner. The War of 1914–18 changed all that. With the massing of troops unaccustomed to infection in malarious regions, malaria became rife among the combatant forces. With the return of these to their homes, and the interchanges of peoples which took place after the War, the disease revived among the civil population in all sorts of unexpected places: in the eastern half of England, the north coast of Germany, parts of Italy long free from malaria, up in the arctic at Archangel; while a terrible epidemic decimated vast areas of Russia.

That malaria would be important to the armies in Europe and elsewhere was foreseen by Laveran, Ross, Nocht, and a few other malariologists; but their warnings were unheeded. How important it proved may be judged from a few figures. In East Africa the average strength of Allied troops was about 50,000. Admissions for malaria in 1916 and 1917 have been estimated at 120,000. In Macedonia in 1916 the French could put into the field only 20,000 men out of a force at least six times this strength. On the same front the British had 30,000 men down with malaria in 1916, 70,000 in 1917. In 1918 more than two million service days were lost on account of malaria.

It is not my purpose, however, to review the whole subject of malaria in war (see Christophers[2]), but, as part of a discussion on the relation between pure and applied biology, to use the subject of malaria as a text from which to illustrate the ways in which pure biological research can help the practical man, and the almost greater frequency with which empirical results provide the starting point for fundamental work.

Let us first summarize the theories of malaria transmission as they are accepted to-day. Malaria is caused by Plasmodium, of which there are three or four species producing in man clinically different varieties of the disease. The sexual forms of the parasite mature and conjugate in the stomach of the mosquito, giving rise to numerous 'sporozoites' which invade the salivary glands and are injected into man when the mosquito feeds. This cycle takes place only in Anopheles. All the members of this genus, which contains some 150 species, are therefore potential carriers of malaria. But in fact relatively few of these species are important—indeed only a proportion of those which breed near human habitations and feed readily on man. In regions of endemic malaria, the local population, while harbouring plenty of malaria parasites, acquires a certain tolerance to the disease (the existence of a true immunity is a much debated question). Such people are the source of the infection which wreaks such havoc among unseasoned troops quartered in their midst.

To consider now the carriers of malaria in the areas of present or prospective hostilities. The chief carrier of malaria in Europe is *A. maculipennis*; a species which breeds in swamps and grassy pools and slowly flowing rivers. It is the species responsible in the Roman Campagna, and many other coastal regions of Italy, Sicily, and Sardinia; the carrier in the notorious Struma Valley in Macedonia, the low-lying parts of Albania and Greece, the coasts of the Black Sea.

Before the War of 1914–18, malaria in Europe was thought always to be associated with low-lying country of this type. It came as a complete surprise to find that malaria was often most intense in mountainous regions. The Germans discovered this in the Taurus of Anatolia, the Italians in southern Italy, the Allies in Palestine. In the eastern Mediterranean rain falls only in the winter. In the spring the streams from the mountains are raging torrents unsuited to mosquito larvæ; but as the summer advances these streams are reduced to broken pools or trickles among stones and provide the breeding places of *A. superpictus*, a species rendered all the more dangerous because during the summer the people concentrate around the few remaining sources of water.

Egypt has commonly been regarded as comparatively free from malaria—because it is not conspicuous in the large towns and military cantonments. But it has recently been realized that there is much malaria, carried probably by *A. pharoensis*, among the rice cultivators of the delta region.

Moving westward into the dry regions of North Africa one would expect malaria to be absent; and that is true enough of the open desert and of the coastal zone of Cyrenaica. But it is not true of the oases. Jarabub and the other oases of the western desert, Kufra and other oases of Fezzan are all intensely malarious. The carrier species is not fully proved but is probably *A. multicolor*, a mosquito that thrives in brackish or highly saline water.

---

* A paper forming part of a discussion on the "Relation between Pure and Applied Biology" held by the Association of Applied Biologists and the Society of Experimental Biology at the London School of Hygiene and Tropical Medicine on March 28, 1941.

In the coastal belt of Tripolitania the situation is different. Here are streams running into the sea. These have been blocked by settlers to assist in irrigation. Swampy breeding places for *A. maculipennis* have thus been created, and recent years have seen a great increase in malaria.

In Africa south of the Sahara there are some thirty species of Anopheles but only two are really important. *A. gambiæ* is a ubiquitous species that breeds in rainwater puddles, borrow pits, river pools or quiet backwaters—any water freely exposed to sunlight. In dry regions like Somaliland its prevalence is related to local rainfall. It is the most dangerous Anopheline in the world—its introduction in 1932 from Dakar to Brazil is one of the major health disasters of recent times. It constitutes a threat to the southern parts of the United States, and has caused America to invoke the principle of 'hemisphere defence'. *A. funestus*, the other dangerous African species, is confined to the grassy edges of slowly flowing streams. Such waters are often perennial, so that this mosquito may keep malaria smouldering in a locality until local conditions of rainfall and temperature favour *A. gambiæ* and initiate an epidemic.

That is an over-simplified account of malaria transmission; and particularly so in regard to *A. maculipennis*. For the local abundance of this species bears no relation to the incidence of malaria in Europe. The current explanation of this phenomenon of 'anophelism without malaria' must, in the interests of brevity, be set forth dogmatically[1]. It is that the species *A. maculipennis* is made up of a number of biological races or varieties which differ in their habits and so in their capacity to convey malaria. Morphological differences between these races were at first sought in vain. Systematic entomology, which is often twitted for excessive zeal in subdividing species, proved too superficial for the task. Later such differences were found in the structure and pattern of the eggs. To take a few examples: race *messeæ* with richly patterned eggs and race *typicus* the eggs of which have two bars on a white field, breed in fresh inland waters; they feed almost exclusively on cattle and the chances of their taking the necessary two meals from man at the appropriate intervals are so remote that, with few exceptions, areas where these are the prevalent races are free from malaria. Race *labranchiæ*, with small egg floats and a more uniform pattern, is a brackish water breeder of the western Mediterranean (Italy, Sicily, North Africa). It is far more prone to bite man, and its prevalence is always associated with malaria. Race *elutus*, with no egg floats or pattern, is a brackish water breeder of the Balkans and the Near East. Precipitin tests on the blood in wild caught females have shown a preference for human blood; and wherever this race occurs it is a dangerous carrier. Race *atroparvus* is more puzzling. Its chief area of distribution is the Atlantic seaboard of Europe. In egg type and breeding habits it is allied to *labranchiæ*, but whereas in some localities it attacks man and conveys malaria, in others it seems to be diverted to cattle, and malaria is absent. Perhaps there are differences in the housing of man or animals which will account for this; perhaps there is not one *atroparvus* race but several.

In *atroparvus* regions (around Amsterdam for example) malaria is often a house disease. Instead of going into complete hibernation in the winter (as does *messeæ*, for example) *atroparvus* females will continue feeding and so transmitting malaria to the household. But they fail to develop their ovaries, so that they have no call to leave their resting places and fly afield. Here is an attractive problem, presumably of internal secretion[3], directly connected with the epidemiology of malaria.

What is the zoological status of these mosquito races? Here is a field crying out to be worked by geneticists; particularly geneticists prepared to study the genetics of *behaviour*—for it is the natural history and behaviour of these insects which are important from the malariologist's point of view. A little has been done by the malariologists themselves. Only the *atroparvus* male has so far been persuaded to mate in small cages. Crossed with females of the other races, varying degrees of infertility are revealed, lethality supervening at varying points. With *messeæ* most of the eggs are sterile; with *elutus* the larvæ die; with *typicus* sterile adults of both sexes result; with *labranchiæ* all the resulting females are normal but only a part of the males.

That being the malaria situation, what is the Army doing about it? The general plan (Perry, Manifold, *et al.*, see Christophers[2]) is to establish mobile malaria laboratories. These are commanded by officers with wide experience of malaria in the tropics; their commissioned staff includes malariologists and entomologists; the senior non-commissioned officers will be young graduates in biology or senior laboratory assistants. The function of these units will presumably be to instruct the field hygiene sections in general anti-malarial work; to provide all the necessary local information regarding the incidence of malaria in the local population, and the breeding places, habits and infectivity of the dangerous species;

and to advise on specific measures of prevention.

As an organization this seems well conceived. What it will achieve in practice must depend, as in all human enterprises, upon the abilities of the people doing the work. For there is no rule of thumb in malaria control; each problem is a local problem which must be approached with an open mind. It is where the malariologist has applied blindly, in a new locality, methods which he has found successful elsewhere, that the disasters have occurred which have brought the subject into disrepute.

The methods of malaria prevention still call for investigation. Of all the single measures, sleeping under a mosquito net is perhaps the most valuable. That should be practicable in base camps; but is it possible to devise a bivouac net for use by troops in the open and to persuade them to use it (see Manifold, *loc. cit.*[2]) ?

In the past, little value has been attached to the destruction of adult mosquitoes; but where semi-hibernating *atroparvus* are the cause of malaria this is a most important measure. Under war conditions there may be times when it is the only practicable measure. It involves the whole subject of insecticidal sprays and the methods for dispersing them.

The abolition of breeding places is often an engineering problem of a special kind. The engineer must turn malariologist or vice versa; or the two must co-operate. That is a vast field beyond our scope. One form of engineering control consists in connecting the breeding places with the sea. What factors—water movement, predators, salinity—are here concerned would repay investigation.

Increasing use has been made recently of 'flushing' to control stream breeding mosquito larvæ[4]. Siphons are built into the stream which periodically release a large volume of water. It is believed that larvæ migrating to the margins of the stream are stranded as the flow subsides, but the question merits study.

The classical method of killing mosquito larvæ is by applying oil to the surface of the water. This does not, as is popularly supposed, suffocate the larvæ by preventing their breathing at the water surface. A little of the oil enters the tracheal system of the larva and the oil contains poisons which affect presumably the nervous system. A vast amount of empirical information exists on the preparation and application of oil mixtures, but exact knowledge is scanty. We know almost nothing about the toxic constituents of the oils used.

Oil is usually applied as a spray to form a layer 15–20 μ thick. Equal in importance with toxicity is the ability of the oil to form a stable film of this thickness on the water surface. As a result of an investigation financed by a group of oil companies and carried out at the London School of Hygiene and Tropical Medicine by D. R. P. Murray[5], some light has been thrown on this problem. If an oil contains polar substances such as naphthenic acid or long-chain fatty acids, with a strong tendency to form mono-molecular films on the water, these may spread out ahead of the oil, occupy the water surface, and force the main body of oil into lenses or droplets. Indeed, it has been observed in practice in Malaya that if the coolies waded in the water, an oil which previously spread might be prevented from doing so by oil films coming from their bodies[6]. Such resistance to spreading, or general instability in the oil film, may, however, be overcome by the presence in the oil of 'spreaders'. These are of unknown composition but include 'cracked spirit gum' (derived from polymerization of olefinic hydrocarbons), certain resins, and some constituents of petroleum residues, particularly the undistilled residues of aromatic concentrates. The efficiency of such 'spreaders' in a given oil may be gauged by the direct measurement of their spreading power against surface contamination in the Adam-Langmuir surface pressure trough.

The difficulties of this subject of oils are made greater by the fact that the experimental materials are largely of unknown composition. Mixtures on the market with the same names have often been produced not only from different oil wells but also by different processes. It is clear, however, that a physico-chemical specification for an anti-malarial oil is urgently required. Provisionally we carry out three rough empirical tests: the oil should have a greater spreading pressure than that of castor oil; it should form a fairly complete stable film when sprayed on water in the customary amounts; and Anopheles larvæ below such a film at 24° C. should all be dead in two or three hours.

With some types of water, notably where much vegetation is present, 'dusting' is preferred to oiling. This consists in blowing over the water a cloud containing one or two parts per cent of Paris Green in a vehicle of dry dust. Anopheles larvæ feed at the water surface and are poisoned by the floating particles. Apart from some information about the size of particle ingested by the larvæ, knowledge of this subject is at the empirical stage.

The last method of control I intend to mention (there are many more) is known as 'shading'. This has been developed principally and with great success by Ramsay[7] in Assam and northern Bengal against *A. minimus*, a species closely allied to *funestus*, and which likewise breeds in grassy edged streams. It has been found that if suitable bushes are planted along these streams so that they are densely shaded, *A. minimus* disappears. But the cause of its disappearance has been a matter for speculation. Does the female avoid shaded waters in laying her eggs ; or is the shaded water unfavourable for the development of larvæ ?

During the last three years R. C. Muirhead Thomson[8], supported by the Royal Society and the London School of Hygiene and Tropical Medicine, has been working on this problem in the tea gardens of Assam. Briefly, he has shown that although the female *A. minimus* lays her eggs during the night she prefers to lay them in the shade. At a light intensity one quarter of starlight she will still show a preference for deeper shade ; below 0·000008 ft. candle, about one tenth of starlight, she becomes indifferent. Yet egg collections in the field show that she does not lay in the shaded streams. Thomson has proved that this is because she will not lay in moving water. Under laboratory conditions she refuses to lay in water flowing at a rate of 0·05 ft. per sec. Normally she finds both shade and still water among the grass at the margins of the streams. All this vegetation is eliminated by shading.

Shade also exerts an effect upon the larva. Contrary to general belief these stream-breeding larvæ have very weak powers of resistance to flowing water. *A. minimus* larvæ cannot remain anchored if the rate of flow exceeds 0·29 ft. per sec. They normally find the still water necessary to their security in the grassy margins. They are kept there, not by an avoidance of moving water but by a reaction to light and shade which is enhanced by flowing water.

In this reaction to light are several elements : (1) a photokinesis or increased activity in bright light. This may be inhibited by thigmotaxis if the larva is anchored to some object. (2) An undirected avoiding reaction on passing from shade to light. (3) A directed reaction or phototaxis towards an area of shade. Under experimental conditions the larva can be made a victim to these responses, and by shading the middle of a stream can be caused to leave the margin where it is safely anchored and swim to the middle, where it is swept away by the current.

This work illustrates well enough how right the malariologist may be in his methods and how completely in the dark as to their mode of action. He has no time and often receives no encouragement to probe deeply into such matters. Here lies a vast and profitable field awaiting the attention of research workers informed on modern biology and unhampered by the need of producing immediate practical results.

APPLICATION OF PLANT GROWTH SUBSTANCES IN PRACTICE*

By Dr. M. A. H. Tincker
Royal Horticultural Society's Laboratories, Wisley

In order to focus attention on certain aspects of the application of biological science to those industries concerned with the growing of plants, it is proposed to consider briefly one example, perhaps already familiar to some readers of NATURE.

THE FUNDAMENTAL RESEARCH

For very many years it was a commonplace observation that the stems of most plants usually grew towards light, yet the elucidation of the mechanism involved took place comparatively recently. The physiological investigations of tropisms, as such growth movements are called, were carried out in university laboratories at Copenhagen by Boysen Jensen and at Utrecht by F. A. F. C. Went and his associated workers ; during the years 1910–27 they progressed steadily yet bore no obvious signs of having any practical application.

In 1927 Went[1] reported the isolation from, and reintroduction to, the tissues of seedling oats of one (or more) active hormone capable of controlling the rate of growth in length of the tissues of the young shoot. A technique was gradually perfected whereby minute traces of the active substance could be estimated in relative but quantitative terms, or 'oat-units.' Some six years later a team of biochemists led by Kogl[2] determined the chemical composition of auxin *a* and its related form *b*, as these hormones were named ; they proved to have an elaborate structure (*a* $C_{18}H_{32}O_5$). Whilst searching for a ready source of these compounds Kogl tested urine; by good fortune he found a third substance with activity of a similar high order of magnitude, 25 million oat-units per milligram, but of much simpler constitution.

---

* Substance of the second paper contributed to the discussion held at a joint meeting of the Association of Applied Biologists and the Society for Experimental Biology held on March 28

This was quickly recognized as indolyl-3-acetic acid, a compound soon readily available for numerous investigators to apply to the tissues of many plants in various ways[3].

SOME OF THE PLANT RESPONSES

Small quantities in lanolin, at 0·1 per cent, applied to the stems of quickly growing plants such as tomatoes, caused twisting and bending of the stems and petioles and drooping of the leaves. After 24–48 hours, rapid cell division had begun in the region of the cambium and inner phloem and elsewhere. After a week or 10 days the division of the cells resulted in root formation, and in moist conditions these roots emerged to the air through the outer tissues. This was a response of high potential practical value and at once attracted the attention of applied biologists familiar with the problems of vegetative propagation[4].

Another response observed was the retardation of the development of buds on the stems.

CHEMICAL EXPANSION

Using other plant tissues, sweet-pea stems, as testing materials, Zimmerman, Wilcoxon and Hitchcock[5] added to the list of active substances α- and β-naphthylacetic acids, indolylbutyric acid and other substances and later (1936[6]), the esters of these and other related acids which, like the metallic salts, also proved active. As numerous additions were made it became increasingly difficult to correlate chemical configuration with physiological activity. Linser[7] in 1938, cited more than fifty active substances; among more recently added compounds may be mentioned naphthylacetamide and thionaphthylacetamide (Stoutmeyer[8]) and naphthylideneacetic acid (Tincker[9]). Stereo-isomerides may differ in their activity as shown by Zimmerman[10] with the cinnamic acids and by Tincker with the naphthylideneacetic acids. Although indolylacetic acid is closely related to tryptophan, which is a possible precursor in plant tissues when parallel deamination is carried out with tyrosine and phenylalanine and histidine, the activity of the acids so derived is of a low order.

APPLICATION IN PROPAGATION

The earlier attempts were made using lanolin pastes applied directly to the stem, or after glycerine had been rubbed into the tissues, or into longitudinal incisions made in the stems of woody cuttings. Laibach[11] was able to accelerate the rooting of cuttings of the apple stock Doucin XI, and of *Prunus mahaleb* and to increase the number rooted of *Parrotia persica*. Among early successes may be mentioned Cooper's[12] experiments with lemons and Zimmerman's[13] with American holly treated with dilute solutions. In Great Britain from early 1936 onwards, extensive tests of naphthylacetic, indolylbutyric and indolyl acetic acids have been made with a wide range of plants at Wisley, and at Kew by Templeman and Metcalfe[14], at East Malling by Pearse[15] and Garner, also at Reading by Stoughton and Plant[16], and elsewhere. In 1939 an index was prepared by Pearse[17] showing the practical results with these substances; a thousand entries were obtained. Among economic plants, fruit stocks, bush fruits, coffee, citrus and vines occur in this list. Thus after three or four years of applied work it may be justly claimed that the use of these substances was established.

Among plants well known to be difficult to propagate vegetatively there is a gradually decreasing number of unresponsive species. Thimann and Lisle[18] have reported success with *Tsuga canadensis*, *Picea pungens*, *P. abies Pinus insignis*, has responded at Wisley[22]. Grace in Canada tested the Norway spruce[19]. Afanasier tested Betula, Acer and Populus[20]. Such results are directly applicable to forestry, as are those of Plank[21] with pine seedlings. To-day these results have added significance if our forests are to be maintained. Chrysanthemums are readily propagated, but the increased number of roots and larger root systems obtained by treatment is considered, by certain large firms, to be justified. The tests were made on a very large scale involving several hundred thousand plants. Thus was the 'mass production' stage reached.

The treatment given to cuttings varied in concentration with the nature of the tissues—herbaceous or woody. The response obtained varied according to the season of application—generally leafy cuttings responded better than hard wood. Over such details, perhaps of little interest to the experimental biologist, must time be spent by some biologist, for sound advisory services afford perhaps the best of all introductions to an industry in which skilled operators are rightly both critical and proud of their own achievements. Although greatly facilitating propagation, the use of these compounds does not replace technical skill.

Following the work of Bonner[23], Green[24], and Robbins[25], who found that vitamin B_1 (aneurin or thiamin chloride) was necessary for the continued growth of roots, *in vitro*, other investigators (Went, Bonner and Warner[26]) reported that traces of B_1 accelerated the rate of root growth. When added to the growth substances and applied to cuttings at Wisley[22] the results proved very uncertain (certainly aneurin did not alone induce root formation), and only in a very few cases did it cause more rapid growth of stems or roots. More encouraging results were seen at Leverkusen in 1938.

ASPECTS OF MARKETING

By the aid of various solvents, proved not toxic to the plants at the ultimate dilution employed, solutions became available. The results obtained quickly attracted the keen attention of enterprising chemical firms. In the United States indolylbutyric acid was marketed 'under licence', or some measure of supervision of the research institute that proved its value. Other firms, some perhaps less scrupulous, copied this venture. In Great Britain one firm quickly marketed a readily available but relatively ineffective compound. Its sales were on a small scale. Naphthylacetic acid was later marketed in solution but was not sold pure ; to it was added a mixture of carbohydrates, contrary to some advice tendered at the time. Although effective as a rooting stimulant this solution was promptly reported to become 'cloudy' and to encourage bacterial and fungal decay in some cuttings. Another firm was therefore approached and indolylbutyric acid was consequently marketed ; it also appeared under a trade name but the contents were declared. A further firm marketed the solutions under their chemical names giving full details of the contents.

Powders are now available[27] in which the active substance is diluted with talc, fuller's earth, or similar inert substance. Although speedier to apply—the wet cuttings are quickly dipped into the powder and sufficient adheres—they are not quite so effective as solutions. They may be purchased in different concentrations. Another form of preparation is in pellets, made to dissolve in readily measureable units of water, thereby solving the problems of dilution for amateurs. Other devices for obtaining correct dilution have been marketed, including small measuring tubes and dropper measures. Instructions are usually provided.

The advertisements of our reputable firms have, on the whole, adhered strictly to the facts ; the same cannot be said of all firms in all countries where "miracle rooting solutions" are advertised.

The dissemination of knowledge of these substances and their proper use has been carried out by articles in popular papers, in the gardening Press, by broadcasting, by exhibits at shows, by advisory letters, lectures to trade guilds, and other means, including advertisements.

APPLICATION OF GROWTH SUBSTANCES TO ENTIRE GROWING PLANTS

Grace[28] reported that seedlings watered with indolylacetic or naphthylacetic acid at certain concentrations between 10^{-7} and 10^{-8}grew more vigorously than did controls or seedlings receiving heavier applications, which damaged the tissues. The plants tested were Nasturtium, Salvia and tomato. More stimulation occurred in sand than soil. Similarly Amlong and Naundorf[30] reported stimulation, but Templeman[31] found that indolylacetic, naphthylacetic and ascorbic acid gave no significant increase in dry weight when applied as a spray or by watering the soil with solutions.

In a series of experiments made at Wisley[3] with dilutions varying from 0 through 10^{-7} to 0^{-1} indolylacetic acid, naphthylacetic, tetrahydronaphthylideneacetic, glyoxaleneacetic and other compounds proved ineffective, for no stimulation was observed. The plants used were annuals. Templeman and Marmory[32] obtained generally similar negative results with lettuce, with mustard and tomato.

Grace[33] reported stimulation with indolylacetic acid and naphthylacetic acid at two parts per million seed weight, when dusts were applied to grain at the rate of ½ ounce per bushel. Later Grace found that the application of the growth substances to cereal seeds more than overcame the ill effects of grain treatment with formaldehyde.

In a field trial McRoster, Hopkins and Grace[34] again obtained increases in yield, 13 per cent grain and 20 per cent straw, but the results were variable. The growth substance was applied with a proprietary mercury fungicide. Croxall and Ogilvie[35] obtained with peas, in sterile soil, an increase in dry weight by treatment with various seed dressings to which growth substances were added. They also found that the check to growth caused by mercurial dressings was largely or entirely overcome by the addition of naphthylacetic, indolylbutyric and naphthylideneacetic acids. The crop yields were greatly increased—up to 80 per cent increases were found.

A somewhat similar experiment at Wisley gave negative results at early stages of growth. No stimulation occurred with other seeds, including lilies. In a recent private communication, Ogilvie states that with other plants, lettuce and beet, he has not obtained such stimulation as he observed with peas. Similarly Templeman and Marmory[32] found that with oats, wheat, barley and sugar beet, in sand and soil tests, in pot and plot experiments, seed dressings containing naphthylacetic or indolylacetic acid in talc did not stimulate growth or dry-matter production.

Only further work can elucidate these apparently contradictory results ; as yet no recommendations can be safely made to practical growers, and thus in three years little advance has been made in this application.

VITAMIN B_1 APPLIED TO THE SOIL

From its structure thiamin chloride does not appear likely to be a stable substance when exposed to bacterial activity in soils. Yet in the popular American Press extravagant claims have been made of the stimulation to growing plants that results from its application to the soil. In July 1940, some three hundred and fifty firms were selling vitamin B_1 under various trade names. The considered report of the Bureau of Plant Industry shows that no reliance can be placed on the results. Hamner[36] in tests made with long- and short-day plants under controlled periods of light obtained no effect by its use at reasonable rates. It proved quite ineffective. In Great Britain the substance can no longer be purchased as a plant stimulant as it is required for addition to bread. In this matter commercial enterprise has outstripped applied science; perhaps stricter control should be exercised to prevent exploitation of the public, more especially when every endeavour is being made by an increasing number of people to grow more food. Firms of established repute are reluctant to market such preparations for such purposes.

OTHER USES

Gardner, Marth and Batjer[37] applied naphthylacetic acid and naphthylacetamide to fruit trees, and by delaying the formation of the abcission layers prevented the early June drop of apples. This work is now being followed up at East Malling. The formation of parthenocarpic fruits induced by spraying with solutions of growth substances awaits wide commercial application, as does the retardation or inhibition of bud development along the lines of Guthrie's[38] work, but fruit bud retardation in relation to sprays is being studied in Great Britain. The effects of these substances observed by Zimmerman[39], on various storage organs of plants, has not as yet been applied on a commercial scale.

GENERAL OBSERVATIONS

The study of only one example does not permit generalizations of much value to be made, but certain observations bearing on the general discussion are perhaps permissible.

(1) The 'long-range' work undertaken with no thought of commercial practice extended over many years in its physiological and biochemical aspects. It led to the isolation of auxin.

(2) A wide "chemical expansion" whereby many substances were proved active followed during the subsequent five years.

(3) The details such as concentration, time of uptake, or points of technique required some three or four seasons for establishment. Thus the actual application of laboratory discovery to an industry based on seasonal procedure takes several years. Possibly in a few cases this period of testing might be materially reduced, but where plants or crop varieties may react differently the period cannot be greatly reduced.

(4) The actual marketing and use of such substances raises questions of control, of proprietary substances, and advisory services.

The business houses accomplish a large part of the necessary publicity but cannot undertake all the necessary advisory duties. It is essential to make the information readily and quickly available.

(5) The immediate necessity is to remove all obstructions in the flow of knowledge at any point from *A* to *Z*; from pure research to industry. 'Bottle necks' may occur at various stages through lack of co-operation by men of science, and more frequently in the lack of dissemination of accurate information.

MINERAL RESOURCES OF CONTINENTAL EUROPE*

BY DR. W. J. ARKELL

THE BALKANS

The Balkans have for a long time been a region towards which German industrialists, prospectors and geologists have turned acquisitive attention as a source of mineral wealth. The political status of the countries there ranges from some completely subject to the Axis (Rumania, Hungary, and Bulgaria), through a country in process of being freed from Axis control (Albania), and one which has just declared against the Axis (Yugoslavia), to one actively allied for some time past with Great Britain (Greece). Political conditions are as usual so unstable that only a non-political order of treatment can remain valid for any length of time.

Hungary, now in possession of former Rumanian territory, is grouped with the Balkans for convenience.

HUNGARY

Oil. With a production of more than 103,000 tons in 1939 Hungary was nearly self-supporting in oil.

Manganese. By 1938 Hungary was producing her domestic requirements of high-grade manganese ore and exporting quantities to Germany.

Aluminium. Hungary has by far the biggest bauxite deposits in Europe, amounting to at least 40 per cent of the total and perhaps much more. Up to 1937 the production was 25 per cent, second to France (32 per cent). According to some published estimates, the Hungarian total reserve is nearly 500 million tons, which would be by far the largest of any country in the world.

RUMANIA

Oil. With a production of 8¾ million tons of crude oil in 1936, and 6¼ million tons in 1939, after three years of neglect of new drilling, Rumania constitutes the greatest mineral prize in all Europe for the blockaded Axis powers.

Copper was worked extensively by the Germans in the War of 1914–18.

Manganese is produced in many regions. The total reserves are estimated at about 9 million tons of ore with 14–40 per cent manganese.

Chromium. The Germans are reported to have obtained about 40,000 tons of chromium ore during the War of 1914–18 and the total reserves are estimated at 2 million tons.

Molybdenum. Rumania is the second largest producer of molybdenum ores in Europe, coming after Norway, with about 14 per cent of the recent annual production, equivalent to 90 tons of metallic molybdenum. The year 1938 showed a great jump in production which indicated that considerable expansion is possible.

Aluminium. It is estimated that Rumania, even with its new frontiers at the end of 1940, contains 20 million tons of bauxite reserves, as yet scarcely developed.

Pyrites deposits are considerable, amounting to about 10½ million tons.

Mica occurs in fair quantities. The production in 1936 was 66 tons, or second after Sweden, but it has since declined.

BULGARIA

Copper. Bulgaria is estimated to have a reserve of at least half a million tons of probable ore with 4½ per cent copper and more with 2–3 per cent.

Manganese. Germany acquired 30,000 tons a year of good manganese ore from Bulgaria during the War of 1914–18.

Chromium. In recent years there has been a rapidly expanding production of chromite and there are known to be new deposits not yet developed.

YUGOSLAVIA

Yugoslavia is one of the richest of European countries in metals.

Copper. In recent years Yugoslavia has led European countries in the production of copper, with 28·5 per cent of the total in 1937, and the production increased in 1938. The ore body at Bor is the second largest in Europe after that at Outokumpu in Finland.

Zinc and Lead. In 1937 Yugoslavia produced 11 per cent of the European zinc and 26·5 per cent of the lead—a lead production second only to Germany's. The Trepca ore body is the most important source of lead in Europe, with a reserve of nearly 4 million tons estimated to contain 9·5 per cent lead, 5·2 per cent zinc, and some silver.

---

* *Continued from* p. 407.

The Misitsa lead mines produce ore with 11 per cent lead and 5 per cent zinc.

Manganese. Germany acquired 48,000 tons a year of high-grade manganese ore from Bosnia in the War of 1914–18. Since then another extensive deposit has been developed.

Chromium. Production has increased steadily from numerous deposits and Yugoslavia already leads in European production. It is believed that prospecting will reveal still further deposits. The 1937 production of nearly 59,000 tons of ore, containing 28,000 tons of chromic oxide, was equivalent to 45 per cent of Germany's imports in the same year.

Aluminium. Yugoslavia contributes 16 per cent of the total European production of bauxite, and her reserves amount to 80 million tons, or 22 per cent of the proved European total.

Magnesium. Large deposits of magnesite have only recently begun to be worked and many more are still untouched. The magnesite is of the highest quality and could sustain large-scale exploitation for at least half a century.

Mercury. Large deposits of cinnabar occur in several parts of Bosnia and Serbia, and there are others in Dalmatia and northern Macedonia. At one time Serbia alone produced an average of nearly 140 tons of mercury a year (about one tenth that of the Spanish output in 1937).

Antimony. There are important deposits in Serbia and smaller ones elsewhere. With a production in 1937 of 4·35 per cent of the total antimony production of Europe, Yugoslavia easily heads the list of producers. But in 1938 the production was nearly doubled, amounting then to 3,370 tons of metal. This amount is nearly five times the production of the whole British Empire and three times that of the United States.

Pyrites occurs in large quantities at Maidanpek and Bor in Serbia, and also in Bosnia (see under copper).

Mica. In Macedonia there is a workable reserve of at least 300,000 tons of sheet mica.

ALBANIA

Oil. With a production of more than 207,000 tons in 1939, Albania has been a precious source of crude oil to Italy and its loss would be serious.

Chromium. Extensive deposits of good quality chrome ore were recently discovered in the neighbourhood of Lake Ochrida.

Pyrites. Large lenses of high-grade pyrites as yet undeveloped, but easily accessible, may contain a reserve of up to 20 million tons, or 2·6 per cent of the European total.

GREECE

Chromium. Greece, with a production of 42 per cent of the European total, is second only to Yugoslavia (56 per cent). The production has been rising rapidly and could doubtless be stimulated considerably. If Germany acquired control of the mines as well as those in Yugoslavia her needs in chromium would be satisfied.

Aluminium. Production of bauxite increased more than tenfold between 1935 and 1937, to 6·5 per cent of the European production. The reserve is about 5 million tons, or only 1·3 per cent of the European total.

Magnesium. Vast quantities of exceptionally pure magnesite occur. In 1937 Greece accounted for 21·3 per cent of the European production, second only to Austria (60 per cent).

Pyrites. There are reserves of at least 5 million tons. Greece is sixth among the producing countries of Europe.

SPAIN

Iron. Although only accounting for 3·7 per cent of the European output in 1938, Spain contains more than 10 per cent of the European reserves of metallic iron. Among them are some of the largest deposits of Bessemer ore in the world, conveniently placed for shipment.

Copper. The huge pyrites and chalcopyrite deposits at the Rio Tinto mines contain 60 per cent of Europe's reserves of metallic copper. The production in 1937 was only 18·5 per cent of the total European production.

Lead. Spain produces 11·4 per cent of the European total of lead, but only 4·6 per cent of the zinc.

Manganese. There are high-grade ores in many provinces, and the production in the past has averaged more than 100,000 tons a year.

Vanadium occurs in small percentages in lead and zinc veins and also in phosphates. Of the latter there is a probable reserve of 200 million tons with 0·25 per cent vanadium—a total of half a million tons of metallic vanadium.

Mercury. The cinnabar deposits of Almaden are the largest and richest in the world. In spite of primitive methods of working, Spain headed the world production until 1937.

Phosphates. The phosphate deposits of Spain are believed to amount to 23 per cent of the European total (in terms of P_2O_5).

Pyrites. Nearly half the world's total reserve of pyrites occurs in Spain, and 63 per cent of the European reserves. Spain leads European production with about 37 per cent, after which comes Norway with 17 per cent.

Potash. Spain possesses 8·6 per cent of the European potash salts, or nearly half those known outside Germany (the only others being in Alsace and to a much smaller extent in Poland). So far her output does not amount to 5 per cent of the total European production.

PORTUGAL

Copper. About 8 per cent of Europe's copper reserve is in Portugal. In 1937 the production was 5,518 tons of metallic copper, or 3·8 per cent of Europe's total.

Tin. Portugal is at present the only country producing anything but negligible quantities of tin. The amount, however, is not very great (maximum 1,435 tons in 1939).

Tungsten. Portugal produces 94 per cent of the tungsten output of Europe. In 1938 the amount was equivalent to 1,660 tons of WO_3. Germany, in the same year, imported ores to the amount of about 9,000 tons of WO_3; but in 1936, when she was not building up stocks for war purposes so actively, her imports of ore amounted to only about 5,800 tons of WO_3. The Portuguese supply is therefore equal to meeting at least 25 per cent of the normal German demand for tungsten.

Titanium. In 1937, 1,433 tons of ilmenite were produced.

Uranium. In 1936 Portugal had the second largest uranium output in the world, after Bohemia, representing 40 per cent of the European production.

Pyrites. Portugal is responsible for about 10 per cent of the European pyrites production; but her reserves are not one twentieth the size of the Spanish.

SWEDEN

Iron. The Swedish iron ores are the richest in Europe. The production is 29 per cent of the European total, in terms of metallic iron, and the reserve is 13 per cent of the total reserve.

Zinc and Lead occur in important quantities. Sweden accounts for 8 per cent of Europe's zinc production.

Tungsten. Sweden is the only other country besides Portugal that produces appreciable quantities of tungsten. In 1938 she produced tungsten ore equivalent to 108 tons of WO_3 and also exported 1,510 tons of ferro-tungsten.

Molybdenum. About 4 per cent of the European output of molybdenum is produced in Sweden; but the amount could be increased.

Vanadium. The Swedish iron ores, like the German, contain small quantities of vanadium, which is recovered during the smelting, both in Sweden and in Germany. The percentage is low; but the aggregate recovery of vanadium is highly important.

Titanium. Most of the Swedish iron ores are more or less titaniferous, like the Norwegian. The Taberg ore body especially contains 4–10 per cent titanium and could yield large quantities of titanium if necessary.

Arsenic. One of the world's largest deposits of arsenic occurs at Boliden mine, worked for gold, silver, copper and sulphur. The arsenic produced as a by-product exceeds the whole world's consumption.

Mica. The small Swedish mica industry heads the European production with 129 tons in 1938 (34·5 per cent).

FINLAND

Copper. Finland has three important copper districts, which together contain 7·5 per cent of the European reserves of metallic copper and account for 8·6 per cent of the production. Outokumpu is the largest known copper ore body in Europe.

Pyrites. The copper ore body of Outokumpu contains a pyrites reserve of probably 20 million tons, which is about the same as the estimated pyrites reserves of Portugal and Albania respectively.

Asbestos. Finland heads the European production of asbestos, with 43·5 per cent of the total. The bulk of the exports usually go to Germany and Sweden, and since the percentage of the European production within Germany and the conquered territories is only 18, this trade is of importance to Germany.

POSSIBILITIES OF THE U.S.S.R.

To what extent can the U.S.S.R. help the continent of Europe to be self-supporting in mineral resources? Many important metals, especially copper, lead, tin, nickel, tungsten, molybdenum and antimony, she imports for her own needs and so competes with Europe. There are, however, a few important commodities of which she has such an abundance that there is a substantial surplus even after her own huge consumption has been met.

Oil. The surplus of production over domestic consumption was 6·5 million tons in 1938 and 7·5 million tons in 1939, and this could be increased by restricting internal consumption. Petrol rationing was introduced in Russia as from January 1, 1941. Russians claim in recent years to have discovered many vast new oilfields containing reserves of more than 6,000 million tons of crude oil, or three times as much as the present proved reserves of the United States and nearly 60 per cent of the world's total reserves. It is still uncertain how far these claims are justified.

Manganese. More than 70 per cent of the world's reserves of manganese ore are in the U.S.S.R., and in 1937 Russian production was 46 per cent of the total world production. It has been stated that under the Russo-German trade agreement of September 1939 the U.S.S.R. guaranteed Germany half a million tons of manganese ore a year, or more than required for the total steel output of Germany, Austria, Czechoslovakia and Poland in the year 1937.

Chromium. In the year 1936 (the latest for which figures are available) the U.S.S.R. had a larger production of chrome ore than any other country in the world, and she exported more than 3,000 tons of chromates.

Magnesium. In the year 1937 the U.S.S.R. produced about 40 per cent of the world's total production of magnesite, far more than any other country. This is of no advantage to Europe, however; since Europe itself has ample deposits and accounted in the same year for 36 per cent of the world's production.

Zirconium. The Kola Peninsula and the Urals contain considerable deposits of zirconium, which formerly were worked successfully and could be reopened in case of need.

Platinum is produced extensively and is a metal entirely lacking in Europe.

Fertilizers. Russians have claimed recently to have proved vast reserves of phosphates and potash in the U.S.S.R., by far exceeding those in all the rest of the world. Central Europe already has a glut of potash salts, but urgently requires phosphates. Russia exported apatite, phosphate rock and superphosphate to the extent of more than half a million tons annually in 1936 and 1937, while in the first half of 1938 the figure rose to a rate equivalent to more than a million tons a year.

Asbestos. In 1936 the U.S.S.R. produced 24·5 per cent of the world output of asbestos, and exported more than 25,000 tons. The exports increased to more than 27,000 tons in 1937.

Graphite. Although in 1935 the U.S.S.R. produced about 38 per cent of the world output of graphite, she exported none in 1937 or 1938.

NEWS AND VIEWS

Yugoslavia

GERMANY'S attempt to fasten a strangle-hold on Yugoslavia by 'diplomatic means' may prove to have been an even greater blunder than the miscalculation of Mussolini's threat to Greece. The Axis powers, like Germany in the War of 1914–18, have shown themselves singularly inept in estimating the force of the spirit of resistance in a free people prepared to endure suffering even to martyrdom in defence of a way of life and a tradition which embody their highest ideals. No doubt the German leaders have been confirmed by their experiences of recent years in a cynical realism which backs mechanized forces against an idealism with little to rely upon beyond the strength of its right arm and the justice of its cause. Yugoslavia, however, stands in a category different from those nations until lately free, which have succumbed to the traitor within their gates. By the bloodless revolution of March 26–27, Yugoslavia, to quote Mr. Churchill, "found her soul". Her three peoples stand united in their resistance to aggression. Nor must it be forgotten that each one of them has a long and honourable tradition in the cause of freedom.

When the German Führer sought to bring Yugoslavia into subjection as Rumania and Bulgaria had been brought into subjection, had he forgotten how the reorganized Serbian army in the War of 1914–18, after three years of exile and eclipse, showed themselves worthy sons of the heroes of the field of Kossovo, how they were the first of the Allied troops to break through the ring of the Central Powers, and how in a drive, which in the difficult conditions of the terrain was little if at all less spectacular than some of the recent advances of British troops in Africa, expelled the enemy from their country within a few weeks? Now Yugoslavia has been forced to take up arms, her army, composed of men who are among the bravest and strongest fighters in the world's armed forces, aided by the difficulties of a country which offers little facility for the technique of mechanized warfare, may well prove, as it did in the last War, the pivot upon which will turn the struggle on behalf of freedom. As in the War of 1914–18 the health of the armed forces will need special attention. During 1916–17, malaria claimed a deadly toll. In fact, medical grounds might well prove ultimately as important as strategic (see page 436 of this issue).

The independence of Serbia from Turkey was established by the Treaty of Berlin in 1878. After the revolution in Austria-Hungary, Slovenia, Croatia, Dalmatia and Bosnia declared their independence, and their union with Serbia, together with that of Montenegro, which had been voted on November 13, 1918, was proclaimed on December 1, 1918, when the official name of the State was announced as being the Triune Kingdom of the Serbs, Croats and Slovenes. Further modifications of boundaries followed, and on October 3, 1929, the name of the State was changed to the Kingdom of Yugoslavia. The estimated population at the beginning of 1936 was nearly fifteen millions. All religions recognized by law enjoy the same rights, and comprise the following: Serbian Orthodox, 48·7 per cent; Roman Catholic, 37·45 per cent; Greek Catholic, 0·32 per cent; Protestant, 1·66 per cent; Moslem, 11·2 per cent; Jews, 0·49 per cent; others, 0·18 per cent. Primary education is free and compulsory. Secondary, technical and agricultural educational facilities are good. There are three universities, namely, the University of Belgrade with about five thousand students, University of Zagreb with about five thousand students, and the University of Lyublyana, founded in 1920.

Agricultural Policy in Great Britain

ON April 3, the House of Commons went into Committee of Supply on a supplementary vote for the Ministry of Agriculture. The Minister (Mr. R. S. Hudson), in his reply to Earl Winterton, pointed out that between 1914 and 1918, before Mr. Lloyd George started his food production campaign, about 32 per cent of the cultivable land of Great Britain was under crops. By the end of 1918 that was raised to 38 per cent. At the beginning of this War, the percentage was only 28, but in the same period it has been increased to 40 per cent. Thus, in the War of 1914–18, 2,300,000 acres were ploughed up, and it is to be expected that by this spring 3,750,000 will be ploughed up. Against this, it must be realized that the population of the United Kingdom has risen since 1917 from 41,000,000 to 47,750,000, while the land available to provide the food has decreased by 2,500,000 acres. Thus, the farming community has made a very remarkable contribution to the British war effort. The farming survey is to be revised and will be of great value for the food production campaign and even more valuable to the post-war agricultural policy.

The Minister of Agriculture is persuaded that the quickest and biggest increase in production can be obtained by increasing the productivity of the existing arable land, improving the existing grassland, and above all by raising the standard of farming. In the last seven months, the various committees have done very nearly as much towards draining land as it took the Italian Government thirteen years to do in reclaiming the Pontine marshes. Many parks, too, have been ploughed up. Golf courses are not so valuable, but where they can make a substantial contribution they will be asked to do so, while those unsuitable for ploughing will be used for grazing sheep.

In regard to research, the Agricultural Research Council is to be granted an increased sum for use at its unfettered discretion for promoting basic or fundamental research (see also p. 434 of this issue of NATURE). Thus it is hoped to use for the advantage of agricultural research the best brains of the scientific world. The Minister proposes to appoint for England and Wales a body which will be directly responsible to him and which will be concerned to devise methods for ensuring that promising results of research are applied as rapidly as possible to the problems of agriculture and incorporated in the everyday practice of the farmer. A similar body is to be appointed for Scotland. The question of the reform of agricultural education is also to be considered.

Science and Democracy

THE American Association for the Advancement of Science recently forwarded to the British Association a resolution adopted by its Council, inviting the collaboration of British men of science with their American colleagues in framing a charter of democracy on scientific principles. The resolution was passed to express whole-hearted support of the rights of free peoples of the world and the desire of scientific men to share in the responsibility of maintaining them at this time of international stress. It was intended as a significant joining of 'hands across the sea' in a common cause and with the hope that the grasp might lead to effective action.

When this expression of unity of feeling and purpose with Great Britain in the present War was communicated to the Council of the British Association, the resolution was referred to the Committee of the Division for the Social and International Relations of Science. It need scarcely be said that the friendly approach from the United States was highly appreciated, and the co-operation suggested was gladly undertaken. The wording of the American resolution invited co-operation "in attempting to formulate, upon scientific principles, an international charter of democracy". It became clear, however, from inquiries that this phrase represented an attitude and a hope, and was not intended to be a precise term of reference for any committee which might be appointed by either of the two Associations to consider the subject. The Committee of the British Association Division therefore decided first to formulate a statement of the democratic fellowship of science, believing that such a charter would include the basic elements of scientific principles of democracy. This charter has been drafted and communicated to the American Association as well as to the Council of the British Association, as a contribution to the co-operative effort of English-speaking scientific communities to promote the advancement of knowledge and action in an international spirit. Whether a charter of the scientific commonwealth can be made the foundation of a world fellowship has yet to be considered.

University of Liverpool: Air Raid Damage

IN a recent raid on Liverpool some of the University buildings suffered damage. One of the engineering laboratories received a direct hit and was practically wrecked. Part of the Medical School was also severely damaged, but the effect here was less direct and the structure is not seriously impaired. Other buildings of the University suffered from blast, many windows, roof-lights, and doors being destroyed. There is, however, no reason to fear that the work of the University will be restricted; the remaining engineering laboratories are adequate to carry on the work of the Faculty with little reduction of efficiency, and repairs are proceeding rapidly on the other laboratories. The amount of the damage is estimated to be about £100,000, so far as it can be ascertained at present. Fortunately, there was only one casualty and that of a minor kind.

Engineers' Achievements under Aerial Bombardment

THE twenty-first annual general meeting of the British Electrical Development Association was held in London on March 21 under the presidency of Lord Lytton. The meeting was preceded by a luncheon at which the Minister of Transport was the guest of honour. In reply to Colonel Moore-Brabazon, Lord Lytton pointed out that, in the last twelve months, the electrical industry has undergone the severest test in its existence. In spite of air attacks, electricity supply has suffered no prolonged interruption, but few of the general public have any idea what this has meant. Too many are apt to take it for granted, like all the other machinery of civilized life to which they are accustomed. In the first place, this 'maintained supply' was due to improvements in the distributing system which were carried out in the years before the War. It would not have been possible at the time of the War of 1914–18. The national pool of the whole industry, the interconnexion of the mains of different supply authorities and the amalgamation of different competing authorities—measures taken during peace-time—made 'maintained supply' possible. But even so, the results achieved during the past year have been due to the individual bravery of the men who operated the supply.

Lord Lytton expressed the hope that the day is not too far distant when we shall again think more in terms of 'development', because, despite the alarums and excursions of war-time days, the electrical industry has an eye—and a very constructive eye—to the future. In so far as anyone can visualize the problems of reconstruction with which we shall be concerned when the War is ended and the means available in solving them, the Association and various sections of the industry have given considerable thought to the many ways in which electricity can make its contribution to the planning and building of a Britain that will at least be a more comfortable place in which to live.

Economics and Finance

IN an address on "Finance and the War" given to members of the Parliamentary Labour Party at the House of Commons on November 9, which has now been published by the Economic Reform Club and Institute, Prof. F. Soddy stresses the importance of distinguishing between genuine and fictitious credit if we wish to put an end to recurring economic booms and slumps and periodic world wars primarily of economic or monetary origin. We live in a world of potential abundance beyond our unscientific ancestors' powers of foreseeing, but that abundance cannot be realized until we clearly distinguish between the creation and the acquisition of wealth. All genuine money reformers are unanimous in demanding that money should not be put into circulation as a debt arbitrarily terminable, and most, if not all, that it should be paid into circulation by the nation for full value received by the nation.

In Prof. Soddy's view, the issue of new money under existing economic conditions is merely one form of forced levy in kind, for new money is a new legal claim by the issuer to anything of equivalent value on the market, with nothing to show that it is new or that the possessor in acquiring it has not given up the equivalent value and so has the legal right to claim it back on demand. He urges that the public should be instructed by its representatives that whether Parliament levies upon it, for the purposes of national expenditure, by recovering from it some of the existing money, by taxation, or by issuing new money, the proportion between the two forms of levy in money and in kind is dictated solely by statistical considerations to maintain a constant price-level and the money in proportion to what there is to buy, so as to secure uniform and general prosperity.

Electrical Music

A PAPER on "Electrical Music" which was read on February 1 to the Midland Section of the Institution of Junior Engineers by Dr. W. Wilson and is published in the March issue of the *Journal* of the Institution, summarizes in a very thorough manner the chief existing methods whereby musical sounds can be produced electrically. The most important developments have taken place in connexion with apparatus which actually create musical sounds in the first instance. The first actual mention of music as produced by an electric source was in connexion with Duddell's 'singing' arc, at the end of last century. The resistance of an electric arc decreases as the current rises. The result is that instability is produced, in the absence of a ballast resistance; thus the arc is continually going out and rekindling. If an inductance instead of a resistance is used and the whole is shunted by a capacity, a tuned circuit is formed in which the current will oscillate at a definite frequency. In so doing the current between the electrodes will actually be reversed twice per cycle, the arc going out at each reversal. No serious musical instrument has developed from the singing arc, although it achieved fame as a wireless transmitter when slightly modified by Poulsen. Within the past decade the howling of a valve in a wireless set has been a common example of electrically produced sound and it forms the basis of two musical instruments. Theremin has reproduced the conditions of the oscillating wireless set in his 'etherphone'.

The second application of the oscillating valve is for the construction of a complete electronic organ, a good example of which is that designed by Coupleux and Givelet, and installed in a number of French churches. In this there are 120 valves, which are caused to oscillate singly, and to generate a full range of notes which are very rich in harmonics. A very successful electric organ was invented by Hammond in 1934. In this there are 91 small alternators all driven from a common shaft which is itself driven by a synchronous driving motor. The sound which accompanies a talking picture can be derived from a wave track printed upon the celluloid film, through which a beam of light is projected into a photoelectric cell. Organs have been designed on this principle. In conclusion, Dr. Wilson points out the many advantages of the electrical method of producing music, especially when the electronic organ is employed. The power consumption is very low, it being usually possible to obtain all the energy required by plugging all the supply leads into any ordinary lampholder. The first cost is low, being between 30 and 40 per cent of the ordinary pipe organ, the maintenance costs are low, and it can always be trusted to maintain its exact tuning. Its progress up to the present has been remarkable, and there is every reason to foretell an equally rapid expansion of its use in the near future.

Trends in Air Conditioning

IN an article in the *Electrician* of January 31, some significant trends in air-conditioning plants are discussed. The proved reliability of compact high-speed condensing units has made practical completely self-contained factory-assembled and tested 'packaged' air-conditioning units of ever-increasing size. Last year they reached 25 tons, and there is every indication that they will be increasingly popular. This trend began seven or eight years ago with small, compact, self-contained room coolers of about half a ton capacity, which were offered almost as soon as compact condensing units were developed. Later came the so-called store-type coolers, package units containing a condensing unit, evaporator, fan, and controls, completely piped, wired, charged and tested at the factory. The success of these units and the development of suitable compact, high-speed, condensing units has led to the more recent factory-assembled-and-tested central plant units of 7½–25 tons capacity. Those incorporate the features of a carefully engineered and installed central plant air-conditioning system, but are self-contained in a sturdy steel frame. All piping work, oven vacuum dehydrating, charging and testing of the system are under strict factory conditions. The units are usually placed in a stock room at the rear of a shop, in the basement, or on a balcony, and are connected to the occupied space by means of a suitable duct system.

Radio Traffic Control in America

A NOVEL plan to bring traffic signals into cars in the form of distinctive tones corresponding to the 'stop' and 'go' lights, may in time make a car-radio a legal requirement on every car in the United States. In its present form, this traffic-control system uses the existing car radio tuned to 550 kc., thus making the system immediately available for the six million cars now equipped with auto-radios, though eventually a special small set would be employed with fixed tuning to the highway safety-signal frequency. By the use of this signal, the driver, instead of letting his attention wander from the roadway in his search for traffic signals in unfamiliar territory, would hear a pleasant low tone as long as the lights were green. When red comes on, in all cars in that section of the roadway an interrupted high note would be heard similar to that caused by a crossing signal.

Recorded messages can be used for continuous repetition of a message. The small highway transmitting unit, which may be mounted on a telephone pole or a traffic light stanchion, makes use of a magnetic tape sound-recording device. A distinctive sign placed on the street in advance of a given radio zone attracts the attention of motorists to the radio system which they are approaching and gives them the frequency to which to tune their set. By means of this device, traffic can be diverted to a secondary thoroughfare from crowded highways, preventing jams before cars have a chance to pile up, and drivers can be warned of speed limits or of emergency in case of fire or accident.

Data of Seismology

FROM the Government of India Meteorological Department comes the valuable *Seismological Bulletin* for October–December 1939. Interpretations of readings of the seismograms from Agra, Bombay, Calcutta, Colombo, Dehra Dun, Hyderabad, and Kodaikanal are given. Furthermore, J. H. Sil at Poona has collected 58 non-instrumental reports of shocks, five being in October, eight in December, and the remainder in November. Three of the reports noted earthquakes reaching intensity 9 on the Rossi-Forel scale. By far the strongest shock was on November 21, 1939, at about 11 h. 1 m. G.M.T. At Gilgit stones fell from the mountains, and dust spread all over the valley. At Drosh intensity 9 was reached, whilst at Srinagar the walls of the observatory and other buildings cracked.

The *Seismological Bulletin* of the Riverview College Observatory (New South Wales) for July, August and September 1940, has also been received. The Observatory is equipped with three Wiechert and two Mainka seismographs, the interpretation of the seismograms from which are given. The shock of July 31, 1940, was felt at Cape Nelson, Papua. The earthquake of September 12, 1940, was felt at Rabaul, New Britain, also in the Kokopo district, and at Wide Bay, Pondo, Namatanai and Buka. To this earthquake there were several strong after-shocks. The shock of September 21, 1940, was felt at Queanbeyan, New South Wales, but did no damage. Some deep-focus shocks were recorded, and some slight shocks lacked interpretation, since the area is to some extent troubled with microseisms.

Earthquakes near America

THE United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has made a preliminary determination of the epicentres of the earthquakes of February 9 and February 11. The former had its initial time 9h. 44·1m. G.M.T., and on a basis of reports from 22 seismographic stations the epicentre appeared to be at latitude 40·7° N., longitude 125·4° W. This is in the Pacific Ocean just off the coast of California, in a well-known seismic region. The latter had its origin time 14h. 35·4m. G.M.T., and on a basis of reports from 18 seismographic stations the epicentre was calculated to be latitude 14·5° N., longitude 94·0° W. This is in the Pacific Ocean almost due west of Guatemala in Central America, also in a well-established seismic zone.

University of London: Certificate in Natural History

THE University of London has now published amended regulations (applicable for the duration of the present emergency) for its certificate of proficiency in natural history. The new scheme takes advantage of the fact that large numbers of urban teachers are now located in the country or at the seaside, and so presented with an opportunity of natural history study in the field which, under normal peace-time conditions, would have been impossible. The requirements embrace a directed course of private reading at home, attendance at a practical laboratory course of two weeks duration in the summer, an approved plan of field-work suited to the student's locality to be written up in the form of a substantial essay, and examination. Copies of the regulations and syllabus can be obtained from the University Extension Registrar, University of London, at Royal Holloway College, Englefield Green, Surrey. Several local education authorities are prepared to consider sympathetically applications for financial grants-in-aid from teachers in their areas who wish to study for the certificate.

Occurrence of Larger Fungi in the Tropics

A BRIEF note by E. J. H. Corner (*Trans. Brit. Mycol. Soc.*, **24,** 3 and 4; Dec. 1940) again directs attention to the interesting question of the occurrence of the larger fungi in the tropics. His experience in Malaya is in emphatic contrast to that of G. B. Masefield (*ibid.*, **24,** 64–67; 1940), who had suggested that large fleshy fungi are scarce in number and variety in the tropics generally, and that representatives of some of the better known genera are scanty or absent. Corner's evidence is to the effect that larger fungi are abundant numerically as well as specifically and generically, but that "their fructifications are seasonal, developing quickly and rotting quickly, during the first rains which follow dry weather, and that if one is not able to visit the forest daily during the right fortnight, no trace of these fungi will be found. As for variety, I have found in Singapore some sixty species of *Boletus*, twenty-six species of *Russula*, twenty species of *Hygrophorus*, etc., etc." The evidence, in brief, gives a clear indication that tropical conditions are by no means unsuitable for the higher Basidiomycetes, but that the collector must be on the spot at precisely the right time.

Health of Zanzibar

IN his latest report, Dr. S. W. T. Lee, senior medical officer in charge, Zanzibar, shows that the health services for women and children are improving. The women's clinic is attended by 150–200 patients daily, and in four dispensaries in the country the same work is carried on. Routine medical and dental treatment is given to school children, who all suffer, however, from nutritional defects. School feeding in certain places over a period of three months resulted in improved weight, height and health, but the Government is unable to finance the adequate treatment of all school children. The work of ante-natal clinics has steadily increased, and out of nearly 1,300 cases there was only one death which was due to puerperal sepsis.

Dr. George Oliver, 1841–1915

DR. GEORGE OLIVER, a well-known consultant physician and an authority on the examination of the blood and circulation, was born at Middleton-in-Teesdale, Durham, on April 13, 1841, the son of a surgeon. He received his medical education at University College, London, where he came under the influence of Dr. William Sharpey, the professor of physiology, and University College Hospital. He qualified M.B. London in 1865, and in 1873 obtained a gold medal at the M.D. London examination. Eventually he settled in Harrogate and soon acquired an extensive practice. In 1887 he was elected a fellow of the Royal College of Physicians of London, before which he delivered the Croonian Lecture in 1896, and in 1904 founded the Oliver-Sharpey lectureship in honour of his old master, the object of which was "to promote physiological research by observation and experiment, and to encourage the application of physiological knowledge to the prevention and cure of disease and the prolongation of life". Oliver's aim throughout his career was to make medicine a more exact science than it had been hitherto, especially as regards the blood and circulation; and with that end in view he invented several instruments such as the hæmoglobinometer, hæmodynamometer and arteriometer. He also devoted much attention to the study of the glands of internal secretion, especially the suprarenals, in conjunction with Prof. Schäfer. He died at Farnham, in Surrey, where he had been living in retirement for some years, on December 27, 1915.

Institution of Chemical Engineers: Medal Awards

THE following awards were presented at the nineteenth annual corporate meeting of the Institution of Chemical Engineers held on April 4: *Osborne Reynolds Medal:* Mr. M. B. Donald, lecturer in (and at present in charge of) chemical engineering at University College, London, and joint honorary secretary of the Institution of Chemical Engineers, for meritorious services to the Institution during the year 1940; *Moulton Medal:* Mr. J. C. Farrant, of International Combustion Ltd., for his paper, "A Review of Certain Unit Processes in the Reduction of Materials"; *Junior Moulton Medal and Award:* Mr. S. A. Gregory, of Moussec Ltd., for his paper, "Plant Design in Microbiological Processes"; *William Macnab Medal:* Mr. J. V. S. Glass, of the Castner-Kellner Alkali Co. Ltd., for the best set of answers submitted in the 1940 associate-membership examination of the Institution.

Announcements

WE regret to announce the following deaths:

Prof. Herbert Freundlich, For. Mem. R.S., professor of colloidal chemistry in the University of Minnesota since 1938, on March 29, aged sixty-one.

Commandant J. G. Hackin, of the Free French Forces, formerly professor of archæology and Indian art in the Ecole du Louvre, Paris, by enemy action, aged fifty-four.

Prof. A. Lapworth, F.R.S., emeritus professor of chemistry in the University of Manchester, on April 5, aged sixty-eight.

Prof. J. S. Macdonald, F.R.S., emeritus professor of physiology in the University of Liverpool, on March 29, aged seventy-three.

THE forty-seventh James Forrest Lecture of the Institution of Civil Engineers will be delivered by Prof. E. N. da C. Andrade, Quain professor of physics in the University of London, on April 29. Prof. Andrade will discuss "The Mechanical Behaviour of Solids".

FOLLOWING a long and severe illness, Lieut.-Colonel W. A. Vignoles has been obliged to relinquish his appointment as senior managing director of Messrs. Evershed and Vignoles, Ltd. Mr. J. C. Needham succeeds him in that capacity, and Mr. M. Vines and Mr. D. D. Walker have been appointed additional managing directors. Colonel Vignoles worked as an apprentice with the predecessors of the Company, W. T. Goolden and Co., joining that firm nearly fifty years ago in the autumn of 1891.

DR. HERALD R. COX, principal bacteriologist of the United States Public Health Service, has been unanimously nominated by the Theobald Smith Award Committee to receive the 1940 Theobald Smith award, consisting of a bronze medal and a sum of £200, for his outstanding research on Rickettsia diseases.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Origin and Spacing of Slip Bands

SLIP bands on plastically deformed crystals are very much more equidistant than would correspond to statistical disorder; except in the first stage of deformation, their spacing fluctuates around a mean value which is usually between $0{\cdot}5\ \mu$ and $10\ \mu$. This remarkable phenomenon seems to have a simple explanation. Consider a crystal lattice subjected to a shear stress σ which produces the elastic strain $s = \tan \alpha = \sigma/G$ (G is modulus of shear). Suppose that slip takes place in the slip plane p–p (see accompanying diagram) over an area the linear dimensions of which are great compared with the atomic distance, but small compared with the size of the crystal. The slipped area is surrounded by a dislocation zone D,D, and the stress in its immediate neighbourhood has fallen to a small amount which we assume to be zero. The question is, how far the zone of greatly diminished stress stretches on the two sides of the slip plane.

For a rough estimate, we replace the curved lattice lines AB by two straight lines, one being tangential to AB in points A remote from the disturbed zone, and the other tangential in the point B where the stress vanishes. In other words, we assume that the stress vanishes on each side of the area of slip in a zone of width $d = BC$, and then suddenly assumes its initial value σ. The width d of the stressless strip is easily determined. On one hand, the horizontal shift of the atoms at the slip plane is $BC \tan \alpha = d.s$; on the other hand, it must be at least half of an atomic distance a in the direction of the slip. Thus the smallest value of d is given by

$$s.d = 1/2\ a,$$

or

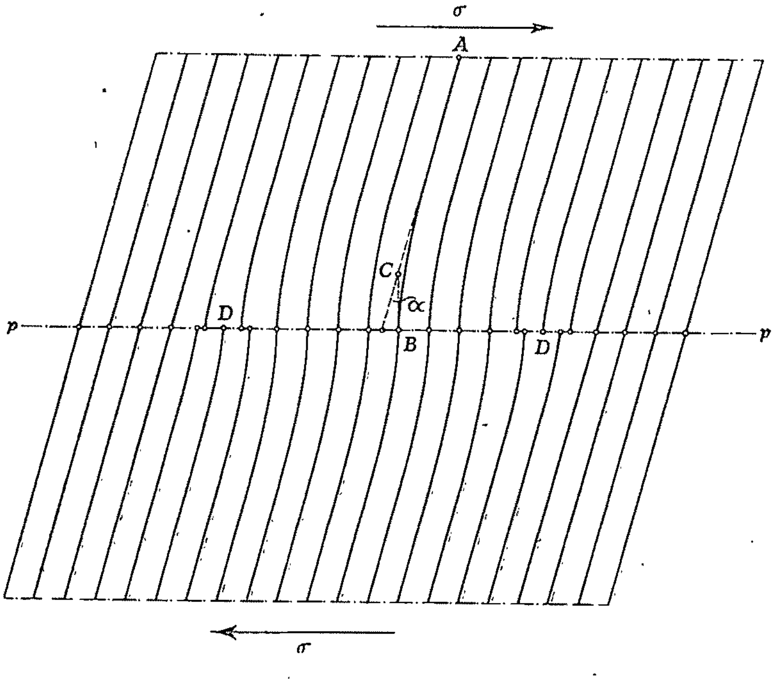
$$\sigma.d = 1/2\ Ga. \qquad (1)$$

In other words, a patch of slip inhibits further slip in a zone of thickness d on each side by annihilating the stress there, and we have to expect that the minimum spacing of slip bands at the stress σ will be d, as given by equation 1.

A better approximation for d may be obtained by calculating the minimum stress which makes two dislocations (the edges of the slipped patches), situated in slip planes the distance between which is d, move past each other. For the special case of parallel straight lines of dislocation, this calculation has already been done by G. I. Taylor[1], with the result

$$\sigma/d = 1/2\pi.Ga \qquad (2)$$

which differs from (1) only by the factor $1/\pi$.



The best-known example of very regular slip bands is that observed by Straumanis[2] on small crystals of zinc grown from vapour. The glide strain was, according to the microphotographs, about 50–60 per cent; the corresponding resolved shear stress[3] is about 160 gm./mm.[2]. With $G = 4{\cdot}08 \times 10^6$ gm./mm.^{2} and $a = 2{\cdot}66 \times 10^{-7}$ mm., equation 2 gives $d = 1{\cdot}1\mu$; the mean value of d, as observed by Straumanis, was $0{\cdot}8\ \mu$.

For different crystals, the stresses needed for plastic deformation generally increase with increasing G, so that the values of G/σ vary within comparatively narrow limits. This explains why the observed spacings of slip bands are usually of the order 10^{-4} cm., a value obtained from (1) or (2) by substituting typical values for G, σ, and a.

According to (1) or (2), the spacing of slip bands should be inversely proportional to the shear stress, except in the first stage of the deformation, when the bands are not close enough to influence each other. This has, in fact, been observed by Yamaguchi[4] on extended aluminium crystals. The product $\sigma . d$, calculated from the measurements of Yamaguchi, has values between 4·9 and 8·7 gm./mm., while (1) gives 0·35 and (2), 0·12. This is probably due to the fact that the slip bands on Yamaguchi's crystals did not extend over the full circumference of the crystal, but consisted of an echelon-like pattern of short overlapping lines, and their number was determined by counting the bands which intersected a perpendicular straight line of unit length.

According to the derivation of (1), the spacing of the slip bands directly reflects the atomic structure of the material; from the spacing of the slip bands and the corresponding stress an estimate of the atomic distance a could be obtained.

An estimate of the molecular shear strength σ_m is given by the formula[5]

$$\sigma_m . b = 1/2\pi . Ga, \qquad (3)$$

where b is the spacing of the lattice planes parallel to the plane of slip. Comparison with (2) shows that the spacing of slip planes is the spacing of the parallel lattice planes, enlarged in the proportion of the molecular shear strength to the actual shear stress.

(1) or (2) may prove of great usefulness for calculating, from the spacing of slip bands, the true internal stresses in individual grains and at grain boundaries in deformed polycrystalline materials. So far these stresses have been inaccessible to measurement.

With a relationship like (1) or (2), the problem of work hardening and creep in a crystal containing an unknown number of active slip planes is reduced to that of work hardening and creep in single slip bands. Together with a new experimental method for the direct measurement of the distribution of slip over the crystal, recently worked out in this Laboratory[6], this should open the way for the solution of the fundamental problem of plastic gliding, the determination of the number of lattice planes actively involved in the deformation.

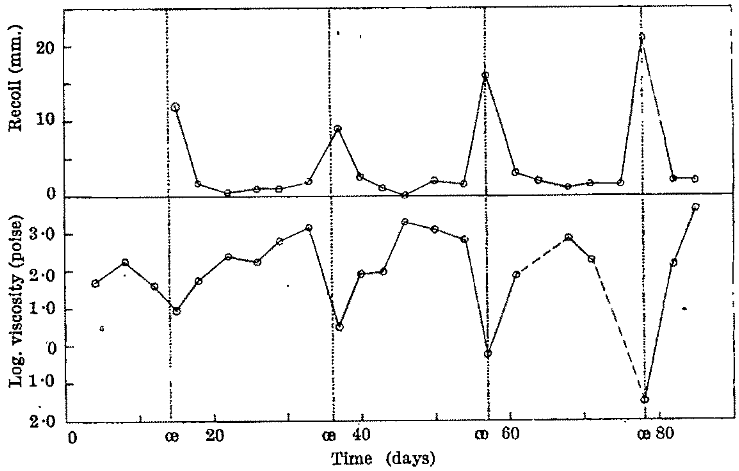
Rheological Properties of Bovine Cervical Secretions during the Œstrous Cycle

The secretions of the cervix of the cow in different reproductive phases have been described by Woodman and Hammond[1] and Hammond[2]. In œstrus, the mucus in the cervix and upper vagina is plentiful and fairly fluid, while in mid-cycle it is greatly diminished in amount and is more viscous. The characteristic stickiness of pregnant secretions has been proposed as a rough test for pregnancy (Marshall and Hammond[3]).

We are making a quantitative study of certain rheological properties of these secretions, which, although not true fluids, give approximately linear flow-curves in a Scott Blair emptying-capillary viscometer[4], doubtless owing to a convenient cancellation of opposite curvatures. The viscosities vary over such a wide range (order 70,000 : 1) during the œstrous cycle, that any reproducible viscosity figure is satisfactory.



Since in this instrument the rate of emptying under constant pressure of an initially full capillary is measured, the linearity of the flow-curves indicates that there must be a marked work-hardening of the material compensating for the known fall in viscosity produced by rising shearing force per unit area. This work-hardening is accompanied by a very large 'flow-elasticity'[5] in the case of œstrous samples, which can be measured in terms of the recoil of the meniscus in the capillary when pressure is suddenly released. The œstrous samples are also remarkably 'spinnbar'[6]. Hammond[2] had already noted the 'stringy' nature of œstrous secretions.

The figure shows the viscosities (plotted logarithmically) and the recoil in mm. for one cow during several œstrous cycles, dotted lines indicating œstrus as observed by the herdsman. Similar effects for a number of other animals have been observed.

Since the flow-elasticity alone gives a clear indication of œstrus and can be determined much more rapidly than can the viscosity, a simple apparatus has been designed ('œstroscope') for use in the cowshed, in which a 5 ml. hypodermic syringe is attached to a narrow glass tube (diam. 2 mm., length 10 cm.) which is filled with secretion by suction. The tube is slowly emptied by pressure on the plunger at a steady rate of about 5 mm./sec., a side-tube closed with the thumb serving as a means of releasing the pressure sharply. The recoil of the meniscus is measured on a millimetre scale.

The secretion samples, which are taken by hand from the neighbourhood of the cervix in the upper vagina, are best homogenized before use in the viscometer or œstroscope by squeezing several times between two glass plates. It is hoped that this technique will serve as an indication and a means for the prediction of œstrus in cows. Further work on samples from pregnant cows is in progress.

Sensitivity of the Dark-adapted Eye during a Prolonged Period of Observation

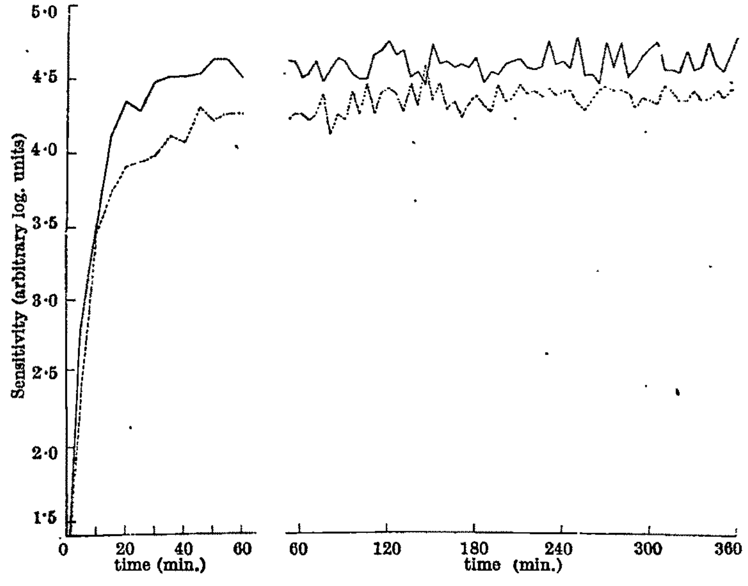
Two related problems of dark adaptation which have important practical applications, but which have received little or no attention, are (1) whether maximum sensitivity, once attained, will last more or less indefinitely, and (2) whether the course of adaptation is affected by fatigue. The experiments here described were carried out to obtain information on the second point, and if the results proved negative, on the first as well.

Observations on the absolute threshold for light intensity during the process of dark adaptation were made by means of Nagel's adaptometer[1], the technique being that described by me elsewhere[2]. Readings were taken following 10 minutes preliminary light adaptation, at intervals of 5 minutes throughout two sessions of 6 hours each, two weeks elapsing between the sessions. I, having participated as subject or experimenter in about seventy experimental dark adaptation sessions, acted as subject. The sessions here described took place following an ordinary day's activity (teaching, research, etc.), ending with 3 hours fire-watching duties, the exact times being 10 p.m.–4 a.m. on the first occasion, and 10.30 p.m.–4.30 a.m. on the second. During the session some black coffee and plain biscuits were taken. (The vitamin A content of these was negligible, and no observable effect on the readings was produced.) I experienced the usual signs of sleepiness, but no acute discomfort.

On the first occasion adaptation was carried out in complete darkness, in the ordinary way. On the second, it was carried out during continuous stimulation with diffused red light, as described in reference[2]. The light was bright enough to read by, though not with ease. The results of both sessions are shown in Fig. 1 and the accompanying table. The ordinates on the curves in Fig. 1 are a measure of sensitivity in arbitrary logarithmic units, corresponding to the reciprocal of threshold intensity at the time of each reading, and representing successive logarithmic steps below the maximum intensity of the adaptometer light. The figures in the table show mean sensitivity measures during each successive hour of the session. From the dispersions of these (as well as by observing the course of the curves) an indication of fluctuation or variability may be obtained. It will be seen that there is a slight upward tendency in both curves throughout the test period, there being in each case only one hour showing a mean reading lower than

	Adaptation during darkness			Adaptation with red light		
1	2	3	4	2	3	4
1	4·245	*		3·895	*	
2	4·612	0·0171	+0·367	4·329	0·0196	+0·434
3	4·625	0·0148	+0·013	4·397	0·0195	+0·068
4	4·614	0·0130	−0·009	4·411	0·0107	+0·014
5	4·638	0·0218	+0·013	4·397	0·0101	−0·014
6	4·648	0·0175	+0·010	4·407	0·0078	+0·010

1. Hour of observations. 2. Mean sensitivity during hour. 3. *P.E.* mean. 4. Increase or decrease over previous hour. * Readings during first hour show normal expected rise, hence their dispersion is meaningless.



COURSE OF DARK ADAPTATION

——— during darkness (initial reading 0·85);

.... with red light stimulation (initial reading 0·94).

N.B. Curves in two portions, with 10 minutes overlap common to both; time scale in second part one-half that of first.

that for the previous hour. These differences, however, are not statistically significant, the probable errors of these differences (not here noted) being in many cases greater than the differences themselves.

The following conclusions can be drawn :

(1) Maximum dark adaptation may be maintained for at least as long as 6 hours. That no falling-off occurs is in accordance with the assumptions or findings (over shorter periods) of most experimenters[3].

(2) The almost complete adaptation previously[2] noted during stimulation with red light can also be maintained over this test period.

(3) Ordinary fatigue at the end of a normal day's sedentary work has no effect on the adaptation process, as measured by the maximum 'level' attained. Nor is the accuracy of observation, as shown by the dispersion of the readings during successive periods, affected. In fact, in the second of the sessions here described, variability became progressively less.

In short, results obtained with a single practised subject suggest that it is possible, at least for some individuals, to maintain accurate observation in the dark-adapted state during a protracted period of enforced wakefulness.

Relation between Colour and Permeability of Insect Cuticles

The same chemical process has been shown by Fraenkel and Rudall[1], Pryor[2], and others, to be responsible for the darkening and the hardening of insect cuticles. Hence the physical properties of the cuticle in light and dark varieties of the same species may be expected to differ. Yellow mutants of *Drosophila pseudo-obscura* and *subobscura*, and less markedly of *D. melanogaster* and *simulans*, lost weight in a dry atmosphere more rapidly than the wild type, whether they were alive or dead, and the dead yellow mutants regained weight more rapidly after drying. The yellow mutants died more rapidly in a dry atmosphere. Similarly the black and ebony mutants of *D. melanogaster* lost water more slowly than the wild type, and survived longer in a dry atmosphere.

The bearing of these results, which will be published in full elsewhere, on the selective advantage of melanism in insects, is obvious. In particular they may account for the surprising frequency, noted by Buxton[3], of black insects in deserts.

Early Exploration of Kent's Cavern

In amplification of the biographical note on the Rev. J. MacEnery in Nature of February 15, p. 202, it may be noted that a demy octavo edition of "Cavern Researches", etc., edited from the original manuscript notes by E. Vivian, was published in 1859. According to the preface to this issue, MacEnery was compelled, after a second appeal, to abandon the project of publishing his researches owing to lack of adequate financial support. Indeed, as MacEnery acknowledges the help he had received in his excavations from several clergymen, including the then Bishop of Bath and Wells, it is unlikely that fear of ecclesiastical censure had anything to do with his decision to refrain from publication.

At the sale of MacEnery's effects a Mr. Lear of Lawrence Place purchased a lot of sermon notes among which, after many years, the above manuscript was accidentally discovered by Vivian, who published extracts from it in the *Torquay Directory*. Afterwards the manuscript was bought by a Mr. W. Long who gave it to Vivian with a view to publication. The notes were in a very rough state but they were rearranged by their editor "as far as practicable in a connected series" without any additions ; the notes on Berry Head cavern were missing.

A large paper edition is stated to have been published, illustrated by sixteen plates which had been previously executed at the expense of the Very Rev. Wm. Buckland, Dean of Westminster.

H. V. Thompson.

32, Queen's Road, Hartshill,
Stoke-on-Trent.

The large paper edition of "Cavern Researches", which is a quarto volume with seventeen plates, and the smaller demy octavo, are in the Library of the Torquay Natural History Society. The former volume has twenty-five pages of letterpress and the latter seventy-eight pages.

The larger volume was published by E. Vivian in 1859, who in the preface mentions that the profits of that edition would be placed at the disposal of the Society, and as the seventeen plates were all executed in his life-time it does not appear that Mr. MacEnery would have been put to much expense in having the work published. His patrons, the wealthy family of Cary of Tor Abbey, surely would have helped their chaplain of nineteen years service had they been sure of his ecclesiastical position if he had required merely their financial assistance, but it is not at all unlikely that as he was a Roman Catholic he would have found it difficult to secure an 'Imprimatur'.

Harford J. Lowe, honorary secretary of the Torquay Natural History Society, in vol. 3 of the Society's *Journal* writes : "Circumstances combined with the want of encouragement and help from the representatives and guardians of his science frustrated his design, while there was also, no doubt, some apprehension of the new facts seriously affecting some of the traditional foundations of the 'Faith' . . . He shrank from such responsibility which ill-health would make appear greater and more serious, and so his sense of duty to Science was outweighed by his doubts and fears respecting its public use and benefit".

A. H. Ogilvie.

The Museum, Torquay.

LANDMARKS IN CHEMOTHERAPY

THE forty-ninth Bedson Lecture was delivered by Prof. C. H. Browning at King's College, Newcastle-upon-Tyne, on March 11, the subject being "Landmarks in Chemotherapy". After defining chemotherapy and summarizing its position in 1900, Prof. Browning traced the search for synthetic compounds with curative action in infections due to trypanosomes, spirochaetes, malarial parasites and bacteria. The first great advance was the discovery of trypan red, with which Ehrlich and Shiga (1904) cured a surely fatal infection due to certain trypanosomes in mice. It had the disadvantage of staining the body tissues and was of little practical value; but it led to Bayer-205, a colourless symmetrically substituted urea derivative. In the case of the latter the ratio of the maximum tolerated to the minimum curative dose is very large; any change, however slight, in its molecular structure causes a great diminution in its activity. It is the most effective drug for the cure of the African forms of human trypanosomiasis, provided that treatment is begun early. About the same time as the discovery of trypan red, the organic arsenical atoxyl was shown by Thomas at Liverpool to be active against trypanosomes *in vivo*. Although inactive *in vitro*, it becomes active in the test tube on reduction to the trivalent arsenic state. Therefore it seems that the drug is reduced in the body or even inside the trypanosome itself. The outcome of the investigation of arsenicals in Ehrlich's laboratory was salvarsan and its derivative neosalvarsan. The latter, especially from convenience in use, has come to be the most important drug in the treatment of syphilis.

For the treatment of malaria, in addition to quinine, Ehrlich and Guttmann in 1891 found methylene blue to be active in the quartan variety. In 1926 Roehl showed that a quinoline derivative, plasmoquine, was effective; it destroyed the sexual stage or crescent of the tropical variety, which is resistant to other drugs. Schulemann (1932) introduced atebrin, an acridine derivative which, like quinine, acts on the asexual stage. It is noteworthy that both these synthetic anti-malarial drugs possess the same sidechain—$NH.CH\,(CH_3).(CH_2)_3.N(C_2H_5)_2$—although they differ in the stage of the parasite which is attacked.

Scientific attempts to destroy bacteria in the tissues date from 1867, when Lister experimented with some success on the use of crude carbolic acid in the treatment of compound fractures. This was an example of the application of a 'surface' antiseptic which could be brought into intimate contact with an infected site.

Up to about 1914 it was believed that an antiseptic must be a general protoplasm poison, harmful alike to the bacteria and the infected host. But this idea was disproved by observations with the newer antiseptics, such as acriflavine and proflavine. An example is afforded by Blake's experiments on trout ova infected with *B. salmonicida*; although carbolic acid is almost equally toxic to both, a concentration of 1 : 2,000 acriflavine will kill the bacteria without appreciably damaging the ova. Experimental streptococcal infections have also been successfully treated with acriflavine as well as certain quinoline compounds of the Schiff's base type (anils), the method being to inject the organisms into the abdominal cavity and then after an interval to follow up with a solution of the drug. Such antiseptics are valuable for the treatment of local infections of wounds, especially as preventives.

As regards the treatment of general bacterial infections, in 1911 Morgenroth and Levy showed ethylhydrocupreine (optoquine) to be active against experimental pneumococcal infection in mice; this observation was of scientific interest only. The first compounds of practical value were the azo dyes derived from *p*-aminobenzene sulphonamide, used by Domagk, such as "prontosil soluble". Tréfouel *et al.* showed that it is the sulphonamide part of the molecule which is effective, and that the removal of the part linked by the azo grouping does not cause loss of activity. Sulphanilamide itself is fairly soluble and rapidly absorbed and excreted. Analogues, such as sulphapyridine, which have proved very useful clinically, are much less soluble and more slowly absorbed, so tending to maintain a more continuous action. Compounds of this class which are effective against streptococci in experimental infections, may fail with staphylococci.

While these drugs have revolutionized the treatment of meningococcal meningitis and gonococcal infections, and have profoundly modified the course of pneumonia, they appear to have little effect on some other infections, for example, tuberculosis.

CONTROL OF TRANSPORT IN GREAT BRITAIN

WHILE Lord Stamp and his fellow chairmen of the four great railway companies in Great Britain have made spirited replies to some of the criticism levelled at the railways in recent months, rail transport is only one aspect of a problem which has aroused widespread concern. The importance of transport in war has been well brought home to us in recent months by the measures designed to save shipping space, and the severity of the attacks on British and Allied shipping. It is only in a limited sense, however, that we have learnt that the power to transport may be the decisive factor, although its bearing on our blockade of Germany has been indicated by Dr. Hugh Dalton. That blockade can only be decisive if transport difficulties, intensified by bombing, reduce the enemy's supplies in his vast territories below what Dr. Dalton calls the 'distributional minimum'. We have yet to appreciate as a nation that the transport problem is a simple problem, and must be governed by national, not by commercial, considerations. The transport services in Great Britain must make their utmost contribution to the war effort without regard to other considerations.

This argument is the basis of Bulletin No. 5, "The Organisation of Transport for War", issued by the Vigilance-for-Victory Group (10 Hertford Street, London, W.1). It recognizes that some of the progressive slow-down of transport has been due to conditions directly imposed by the War, and that the transport services have done their best to overcome their formidable difficulties within the limits imposed by the nature of the transport service. While, however, it is of the utmost importance from the point of view of national defence that our internal lines of communication shall be organized and operated at the highest efficiency, there has been a falling off in efficiency which has substantially reduced the capacity of the transport services. Moreover, the system of internal communications must be considered as a whole. The greatest efforts of the most experienced officers with purely local functions can be frustrated by action in distant parts of the country without anyone being able to relate cause to effect. Failure to combine the highest professional experience with power and responsibility is the root cause of the situation which the recent appointments of two regional port directors are intended to correct.

The bulletin makes the point that transport difficulties are due to failure to co-ordinate transport supply with transport demand on a properly planned and organized basis, as was indeed indicated in Lord Stamp's address. Our present lines of communication are unnecessarily complicated because they have in the main been built up around, or in competition with, a method of railway operating, which however inevitable in the past, is no longer so, and is in itself complex. Statistics of the Ministry of Transport show the very low efficiency of railway operation and serious under-employment of equipment, and this is due to the methods of operating and the very low speed of movement. The delay in clearing ports and distributing supplies, even before mass air-attacks, was due to lack of ways, not of means. There appears to be no real shortage of equipment. The prime cause of the absence of organization is the persistent assessment of transport operations by their financial results and not by their service to national requirements.

The bulletin accordingly proposes that for the organization of our lines of communication for war purposes, the present advisory committee or consultative committees of the Minister of Transport should be abolished and replaced by a Transport Executive Council. Composed of professional transport officers of skill and experience, who would become full-time servants of the State, and functioning very much as the Board of Admiralty and the Army Council or the Air Council, this Council would handle the management and planning of transport services as a whole and decide the broad policy and major problems. The Minister of Transport would be president of the Council, which would directly control all forms of transport, each member of the Council being responsible for a group of departments. Regional organization would also be a matter for the Minister and the Transport Executive Council. While the precise form of regional organization would depend largely on the policy adopted to co-ordinate different forms of transport, it is probable that the simplest and most direct form of control would be through regional transport executive officers, who would exercise full authority over all forms of transport.

The War Transport Council just set up by the Minister of Transport would appear to be a step in the direction envisaged by the "Vigilance-for-Victory" Group.

HUMUS FROM HABITATION WASTES

By Prof. R. H. Stoughton,

University of Reading

THE disposal of the waste materials incident to the existence of mankind has always been one of the major problems of any large civilization. Primitive man, leading a nomadic existence, left his waste wherever he might be. As community living developed, the midden became more and more a necessary part of living conditions, and when towns grew the disposal of waste products began to assume the proportions of a real difficulty. The value of animal and human excreta for the improvement of the soil and for plant growth was discovered by many races; the possibility of returning decomposed garbage to the soil similarly seems to have been thought of at many times in history; the combination of the two appears, however, only to have been practised in early times by the Chinese.

Western civilization developed the disposal of refuse, first by dumping and later by incineration; millions of tons of organic matter are, in one or other of these ways, destroyed at the present time. The wasteful disposal of excreta was later in coming. Until the advent of water-borne sewerage, night-soil still went back to the land, and a great deal of the nitrogen taken from the soil by plants was returned to it in this way. Then came modern systems of sewage disposal and all this 'went down the drain'. But water-borne sewerage, though bringing hygiene and health, brought also new problems of disposal, and thousands of tons of sludge containing only about five per cent or less of solid matter accumulate at every sewage works, and must be got rid of, either by dumping in the sea or by slow drying on extensive beds.

In the meantime our soil is crying out for organic matter. Without organic matter a soil is 'hungry'; its moisture content, the essential key to plant growth, fluctuates wildly with the rainfall, and with its water its soluble mineral content varies. The agriculturist and horticulturist, recognizing the need for organic matter, have for centuries used dung and green manure as the source. Now the supply of animal manures is growing less every year; surely it is time something was done to stop the destruction of all the organic matter in habitation wastes and to convert them into a form suitable for restoring the organic content of the soil.

Lieut.-Colonel F. C. Temple in a recent paper[1] discussed these difficulties and outlined the attempts which have been made to solve the problem of the economic utilization of these waste materials. The

Indore process of which so much has been heard is one such method though, in itself, it contains nothing original; it does not, in any event, deal with the problem of sewage sludge, but is concerned with the combination of vegetable wastes with night-soil and animal excreta. A process is, however, actually being worked at Maidenhead and Leatherhead whereby screened dust-bin refuse, which as it stands is too dry to compost, is used primarily as an absorbent of sewage sludge, which is too wet, and the two together are composted to give a product rich in organic matter and capable, in the soil, of being converted to that ill-understood complex which we term 'humus'. Colonel Temple made out a strong case for an extension of this kind of work, and pleaded for experimentation and a wider vision by municipal authorities. The discussion on the paper showed a sharp cleavage between those who, recognizing the great potential value of such products, wanted to see work directed to improvement and standardization of methods, and those who considered the problem already solved and wished for immediate installation of plant by municipalities.

The Agricultural Research Council, realizing the need for knowledge of what happens when these materials are brought together, has recently financed an investigation at the University of Reading on the preparation of such composts. Such points as the attainment of a correct carbon-nitrogen ratio for satisfactory fermentation, the influence of varying proportions of the two primary components and the proper balance between aerobic and anaerobic decomposition are under study. The problems presented are innumerable; the potentialities are so great as would justify the creation of a research centre for this kind of work alone.

One thing is clear, the product to be manufactured must be 'safe'; that is, it must be so far decomposed that when it is added to the soil, immobilization of nitrogen through diversion of the activities of soil bacteria must not occur, and the carrying-over of pathogenic organisms in the compost must be rendered impossible. The farmer must have no doubts about the materials; once such a product can be made with certainty, a new era in the disposal of habitation wastes will begin.

GEOLOGY AND THE COMMUNITY

A GENERATION ago geology was among the sciences which attracted a wide public interest; at the present time not only has public interest greatly declined, but also there are many workers in other sciences who are almost completely unaware of the content of geology. Yet at no time in the past century have geologists been engaged in pressing forward research in so wide a variety of subjects or engaged in so many investigations of fundamental economic importance. Nevertheless, the nature of their work is but vaguely understood by the general public, and they are not always consulted on problems in which they could give useful assistance, because those concerned are unaware that such matters fall within the competence of geologists.

This decline of interest in geology was used by Prof. P. G. H. Boswell to justify his departure from the traditional practice in presidential addresses to the Geological Society of London, of confining the address to a review of the progress of knowledge in a particular branch of geology; in the first part of his address, delivered on March 12, which he entitled "The Status of Geology", he reviewed the present conditions and suggested ways in which interest in geology may be revived.

Until a quarter of a century ago, the Science and Art Department of the Board of Education encouraged the formation of classes in a large number of sciences, and such subjects as geology, astronomy and physiology were then highly popular. While the work was elementary and the courses were open to criticism from several points of view, it must be admitted that they introduced a large number of citizens to the marvels and potentialities of science, and gave them a proper perspective of the history and activities of man. These courses exerted a cultural influence which was very widespread, and teachers whose outlook had been enlarged in such classes further assisted in the spreading of scientific knowledge. At least, the general public became aware of the existence of some of these sciences.

It is, of course, true that science teaching in schools has made much progress since those days, but to a great extent school science has come to mean physics and chemistry, with biology sometimes added; geology has only rarely been included. With the growth of specialist teaching in these sciences, honours graduates in physics and chemistry were in great demand: such graduates had rarely included geology in their curriculum, and thus were generally unable to continue the tradition of informal teaching which had previously served to keep alive an interest in geology. Therefore, in their impressionable years, while many pupils were left in ignorance of the elements of biology, nearly all were unaware of the very existence of geology. Consequently it is not a matter for surprise that the public should now be indifferent to geology.

The seriousness of this position has been recognized by geologists for some time, and efforts have been made to direct the attention of educationists to the problem. The dearth of geology graduates and the difficulty lately experienced in filling posts (especially in the petroleum industry) laid further emphasis on the need for action, particularly in relation to Empire needs, at a time when in the U.S.S.R., Germany and the United States large numbers of geologists were being trained. In 1935 the position was so grave that Section C (Geology) of the British Association pressed for the appointment of a committee to consider and report on questions affecting the teaching of geology in schools. Reports were published in 1936 and again in 1937: they directed attention to the claims of geology as a school subject, to its cultural value, to the advantage of its outdoor work, and to the demand for trained geologists, while they also made constructive proposals for the inclusion of geology in the School Certificate examinations, both as a separate subject and as a part of a general elementary science course.

It is as yet too early to estimate the prospects of a revival of interest in the subject through school activities. The Science Masters' Association, though composed mainly of teachers without special knowledge of or interest in geology, has readily recognized the importance of the subject by including it in its revised suggestions for a general science course ("The Teaching of General Science, Part II. Science Masters' Association, 1938). Since the War began, the evacuation of city schools to buildings with inadequate laboratory facilities, in rural areas which are often ideal for field work, has done something to stimulate an interest in the subject. But any further progress must depend on the supply of trained teachers, and here the position of the universities is involved.

The number of university students taking advanced courses in geology (apart from those designed for engineering and mining students) has diminished greatly in recent years. While there are several reasons for this decline, there is no doubt that it is due mainly to the growth of the Higher School Certificate examination in England and Wales, and to the granting of exemption from the first year of study in many universities to the holders of such certificates. Although this scheme may have worked well in the training of specialists in chemistry and physics, in existing conditions it has worked towards the elimination of those subjects which are not taught in schools. The choice of a student's university course was frequently made on the basis of the 'Higher' subjects taught in his school: he was 'no good at science' if he had not marked aptitude at physics and chemistry. Possibly this state of affairs would be changed if students were normally required to take a wider range of subjects at the university and to include at least one science which they had not previously taken at school; it is significant that in some Scottish universities, where an honours student in one science may be required to take courses in three or four other subjects, the numbers of geology students are still considerable.

For the more satisfactory teaching of general science in schools, it is clear that graduates having some acquaintance with four or more sciences (and a somewhat more special knowledge of one or two) are likely to be most successful. The growth in awareness of geology, if many students of other sciences learn something of its scope and methods, will be of great value both in education and in applied science.

It is probably owing to the lack of public awareness of geology that so few geologists have been given opportunities to assist in the war effort. Yet, Prof. Boswell emphasized, we hear of deplorable wastage of money and labour (and therefore of all-important time) which geological knowledge would have prevented if it had been applied; he thought that on every Divisional Intelligence Staff in the Army there should be at least one officer in whose training geology had found a place. When the organization of regional commissioners was set up, a geologist was attached as adviser to each commissioner, but apart from occasional inquiries little regular use has been made of geological knowledge. Yet during this time there has been great activity in establishing camps, works, shelters, etc.; the work would have been sufficient to occupy the relatively small numbers of geologists available, but for the most part they have remained unused, having to be content with the knowledge that their qualifications were set out on the Central Register; many have undertaken other service in which their special abilities are lost to the country. Meanwhile, it was noted, there are reports of "operations in which geologists have been given no opportunity to be effective—of works placed in unsuitable locations, camps and reception areas where water is inadequate and drainage unsatisfactory, water-logged trenches and air-raid shelters, and (as though rising in a crescendo of incompetence) the case of an ill-chosen aerodrome site".

The members of the Geological Survey have, of course, been active in a variety of ways, and have done admirable work on many problems which, unfortunately, owing to the exigencies of war-time publication, is not so widely known as it should be. They have been concerned with the investigation of mineral resources (particularly of supplies to replace those normally imported), of water supplies, drainage and other problems. But Prof. Boswell contended that the staff of fifty geologists, even with occasional collaboration of other geologists, is too small to cope with all the difficulties created by war-time activities. Further, he is of opinion that the total number of geologists (including suitably qualified amateurs) available in Great Britain is scarcely sufficient to deal effectively with the numerous problems and the large area to be surveyed.

Even at this stage in the War, there is no reason why it should not be more widely known that geological assistance is available: what is particularly desirable at the present time is that consideration be given to the widespread ignorance regarding the scope and content of geology, so that the available information will be utilized freely when plans for post-war reconstruction are being discussed. This can best be assured if geology regains its position in the educational schemes of Great Britain, so that an acquaintance with its achievements and methods is gained by a larger number of educated people, including those who will be engaged in administration as well as those who will themselves work in, or utilize, the materials of the earth's crust.

FEDERATION AND ITS IMPLICATIONS

Federal Tracts
No. 1: Peace by Federation? By Sir William Beveridge. Pp. 34. No. 2: Economic Aspects of Federation. By Prof. Lionel Robbins. Pp. 32. No. 3: The Colonial Problem and the Federal Solution. By Norman Bentwich. Pp. 32. No. 4: What Federal Government Is. By K. C. Wheare. Pp. 24. No. 5: The Philosophy of Federal Union. By C. E. M. Joad. Pp. 40. No. 6: Socialism and Federation. By Barbara Wootton. Pp. 32. No. 7: Federal Union and the Colonies. By Lord Lugard. Pp. 32. (London: Macmillan and Co., Ltd., 1941.) 6*d*. net. each.

THE wide measure of public attention which the idea of federalism has come to command since the outbreak of the War is already attested by a considerable volume of literature. Several alternatives to the plan proposed in Mr. Clarence Streit's "Union Now" have been closely discussed, and a good deal of attention devoted to problems and difficulties over which Mr. Streit appeared to pass too lightly. If, however, the precise form in which the idea was advocated by Mr. Streit is unlikely to find wide acceptance, the whole trend of events has given fresh urgency and importance to the concept of a union of States.

This urgency derives from two main sources. In the first place, it is realized that if we are to utilize the opportunity which the loosening effect of the War upon our corporate institutions gives us, the mental preparation which must form the basis of any sound plan of world order must be done now, even in the stress of war. Only so can we hope to avoid the mistakes which are bound to be made if we defer the problem until hostilities end and a policy and line of action are demanded without delay. In the second place, our exposure of the Nazi New Order of tyranny and slavery for the subject races should not lead us to overlook the extent to which some semblance of order is implied in such a domination. It imposes on us the obligation of offering to the dominated peoples, when released from Nazi tyranny, not the old disorder, but a new order of free peoples.

These reasons alone give pertinence to the discussions on world order and reconstruction which have been proceeding with fresh vigour during the past autumn and winter, and to the educational campaign which has been fostered by the New Commonwealth, Federal Union and other organizations. That educational work is indeed fundamental. If opportunities are to be seized by the statesmen of this and other countries when the time comes, they must be assured of the support of an informed public opinion, clearly understanding what is involved in any sacrifices of national sovereignty that may be required.

For this reason alone the admirable series of pamphlets which Federal Union has arranged to publish under the name of "Federal Tracts", with the view of promoting informed discussion of federation, is to be warmly welcomed. These pamphlets, of which the first seven have now appeared, are written by authorities on their subjects and express the personal opinions of the authors. Federal Union as an organization is not committed to the views expressed in any of the tracts, and the writers themselves, while interested in federal problems, will not necessarily be members of the Union.

The first two of these pamphlets are not new. No. 1, "Peace by Federation?" by Sir William

Beveridge, written in February, 1940, for private circulation, was included in the first series of "World Order Papers," published last autumn by the Royal Institute of International Affairs; Prof. L. Robbins' "Economic Aspects of Federation" was originally contributed to the symposium "Federal Union" edited by Mr. Channing Pearce and published by Messrs. Jonathan Cape last year. These two acute analyses of the possibilities and limits of federalism are now given to a wide public and form a fitting introduction to the series. Together with the fourth pamphlet in the series, "What Federal Government Is," by Mr. K. C. Wheare, they give a fair and concise account of the problems involved in federation as they present themselves to-day.

Sir William Beveridge, after discussing the problems involved in selecting the areas to be included in a federation, and the division of powers, outlines very briefly a federal constitution. Much of the interest of his contribution, however, lies in the line of approach which he suggests and his proposals for the new step and for dealing with the difficulty of Germany. His cautious approach is unlikely to satisfy the more ardent followers of Mr. Streit's school, but his insistence on a gradual approach and the necessity of limiting the area of federation will commend his argument to constructive minds. World federation, he holds, is for the millenium. Sir William is concerned with the next peace treaty and with the establishment of a super-national government adequately empowered to defend its authority and maintain the peace.

Federation will come when communities recognize a common interest, for which it is worth sacrificing something of their freedom. Sir William Beveridge does not indeed postulate that nations are even yet ready for federation. He sees no other proposal as likely to achieve order, and he rests his proposals on facts: the spectacular changes in the scientific and material equipment of mankind, making out of date old tribal groupings and isolations, and particularly the special revolutionary facts of the unification of Germany and of aggressive Communism in Russia. These facts between them have changed the conditions of peace in Europe and the forms of government required there.

This practical moderation is characteristic of the series and adds considerably to their educational value as a stimulus to thought. Mr. Wheare indeed lays much of his stress upon the difficulties of federalism. It has normally been difficult to establish a federal government. Its operation requires great skill and tact. Its success depends upon an enormous patience and capacity for compromise among the statesmen who work it. Swift and decisive government is impossible, and deep and dividing issues must be avoided. Compromise, conservatism and legalism must of necessity be the virtues and vices of successful federal government.

It is wise to recall the limitations and weaknesses of federalism when proposals to establish a new federal government are under consideration. Only by taking careful account of them can we avoid disillusionments or placing upon the federation a strain it is not fit or intended to bear. If federal government is not always appropriate or easy to work, it is at least government and order, and if the division of powers is wisely and carefully made, it should be possible to reap the advantages of federation while retaining the capacity for rapid executive action in the appropriate spheres which may be essential for efficiency. Federalism, after all, is not an end in itself, but a means of providing a system of government where people are prepared to surrender only certain limited powers and wish to retain other limited powers, both sets of powers to be exercised by co-ordinated authorities.

Few federations in fact are completely federal, and there is nothing to prevent the adoption of strict federalism in some matters and only a modified federalism in others. A written constitution is essential, however, for a federal government, and the amending process should be operated unilaterally neither by the federal government nor the State governments—a condition which obviously precludes any consideration of Germany under her present regime entering a federal system. Furthermore, a supreme court which determines the meaning of the constitution in case of dispute, and financial self-sufficiency for each of the co-ordinate authorities, are other essential features of a federal system of government.

Prof. Robbins, and also Mrs. Barbara Wootton in the sixth tract, "Socialism and Federation", cover much the same ground but from different points of view. Prof. Robbins urges the desirability of leaving to the constituent States as much economic freedom as possible and of eliminating the possibility of those conflicts of sectional interest which under independent national sovereignty might be causes of international friction. He urges that what restrictions or regulations are placed on migration and inter-State trade should be imposed by federal, and not State, authority. Similarly, though wide diversity in monetary system and industrial structure might be permissible within the federation, control of money and capital movements within the federation should be essentially a federal function. Again, federal permission or approval should be required for local collectivist experiments which involve restriction or discrimination.

"Socialism and Federation" is a defence of the thesis that socialism and federation are complementary. Social progress is contingent upon international order, and conscious and planned direction of economic life over a wide area is essential, in the opinion of Socialists, to achieve equality and prosperity. A federal constitution which gave concurrent powers to both State and federal governments to legislate on labour matters, providing only that in conflict the latter would prevail, might enable a system of federal minima to be combined with higher standards in the more advanced States while relieving the latter of fear of their low-standard neighbours.

Mrs. Wootton enforces her argument by referring to the decision about European unity which will confront us who reject the Nazi tyranny under which it has been temporarily imposed. Merely to break it is to forget the logic of twentieth century technique and the wider horizons of twentieth century citizenship, and to re-establish only disorder, tariffs, currencies and barriers. To adopt the alternative of transforming the Nazi empire involves a new political framework such as federalism provides.

The fifth pamphlet in the series, by Prof. C. E. M. Joad, "The Philosophy of Federal Union", should appeal to the scientific worker in particular. The philosophy of federal union, Prof. Joad points out, is largely concerned with the question whether the supercession of powers or transfer of functions from national governments to a federal government is possible or desirable, and he proceeds to an examination of the Fascist philosophy of the State, in which he shows that that philosophy is not only unsound and unscientific but also incompatible with federalism. The individual has rights other than those conferred upon him by the State and duties other than those which he owes to the State.

Prof. Joad argues that the State is not a final but a transitional form of human organization, one among many evolved in the course of man's history. Changes in human environment resulting from man's inventiveness have already made it a political anachronism. Man's advances are due to the individual and not to the State, which has hindered, opposed or suppressed rather than promoted creative thought. Indeed the power of the State has become a menace to human happiness as well as to creative thought, and the supercession of the State has become the crying need of our time. The rule of law can only be established if States are deprived of the power to set aside the authority of law as Federal Union proposes.

Prof. Joad, however, goes further. Federal union has a positive philosophy to offer. The outstanding defect of our civilization is the disparity between our powers and our wisdom, our technical knowledge and our virtue, our science and our ethics and politics. Our problem is that of so organizing our lives both as members of communities and as individuals that we may reap the benefit of the new opportunities of living that science has won for us.

Federal union offers its first contribution to the solution of that problem by enlarging the boundaries of the political unit so as to adjust it to the reality of the underlying economic structure. Moreover, in a world where habit has taken the place of principle and State worship has led to ethical anarchy, federal union offers in the brotherhood of man a creed to live for, and in the supercession of the obsolete form of organization which impedes it, a principle to live by. The ethics of federal union prescribe the duty of enlarging the sentiment of patriotism to include within the scope of its concern the members of other States.

Prof. Joad refers finally to the need for strengthening democracy with the conviction that only religion can command, and with the enthusiasm which only religion can generate. It may well be that federal union, he concludes, can only be achieved and the rights of the individual preserved, if the enthusiasm which religious faith can generate can be harnessed in its service. These Federal Tracts are well calculated to inspire that intelligent understanding of the problems involved which forms the basis, not only of an adequate plan and policy, but also of the conviction and enthusiasm required to ensure their execution.

The remaining two of the pamphlets deal with the colonial question. In the first of these, "The Colonial Problem and the Federal Solution," Prof. Norman Bentwich, reviewing the major problems which the colonial territories present, discusses the alternatives possible in a federal system, and emphasizes the impossibility of establishing a peaceful order with an approach to world citizenship, whether by federal union or any other way, unless we are prepared to renounce national advantages and privileges in governing territories inhabited by less developed peoples and to let people in other countries have a part with us. Lord Lugard, writing on "Federal Union and the Colonies", urges that centralized administration is not workable, and advocates supervision of Colonial economic policy by a standing committee of the Federal Council, similar to the Mandates Commission. He stresses the importance of the principle of equal opportunity and the prohibition of racial and religious discrimination, but strongly opposes some federal proposals such as those of Dr. Ivor Jennings.

R. BRIGHTMAN.

LIQUEFACTION OF GASES

The Separation of Gases
By M. Ruhemann. (International Series of Monographs on Physics.) Pp. xiii+284. (Oxford: Clarendon Press; London: Oxford University Press, 1940.) 21*s.* net.

IN the preface to this book it is stated that" it is high time that deep refrigeration received adequate attention in this country". Dr. Ruhemann has therefore written a volume to remedy this lack of knowledge on the part of British men of science, in order that the subject may be taught in the universities. Certainly the average textbook of physical chemistry does not deal in much detail with the working of liquid air and similar types of plant. The reason is quite obvious. The principles of the subject were worked out many years ago. They are expounded in all works dealing with the equilibria of vapour-liquid systems. But their application has become a matter of very specialized engineering practice, naturally confined to those concerns whose job it is to build and operate low-temperature refrigerating plants. It is not the function of the average university lecturer in physics or in chemistry to teach engineering practice to his students. The author's crusade for courses on "deep refrigeration" is therefore unlikely to be taken up with any great enthusiasm in Great Britain. None the less, the book provides a great deal of information which has not hitherto been dealt with in any connected manner. In this respect it is welcome to chemists and physicists alike.

The early chapters deal with the principles of the subject, first with the vapour-liquid equilibria of two-component systems, next with systems of three components. Much recent data are presented in convenient graphical form. There is a chapter on the thermodynamics of gas separation, particular attention being paid to the types of diagram most useful for discussing equilibria in this field. As might be expected, there are full descriptions of the various types of liquefiers, with estimates of the efficiencies reckoned in gallons of the desired liquid per kilowatt-hour expended. Unfortunately from a practical point of view, the capital cost and maintenance of the plant are left out of consideration. While the scientific efficiency is of great interest, the over-all cost of running a plant is the determining factor in its adoption in practice.

Several chapters are rightly devoted to the separation of air into oxygen and nitrogen in either liquid or gaseous form. The isolation of the rare gases is described, but as a matter of interest the details of the method of separation and purification would have been welcomed by the average reader, who would like to know just how the pure samples, now available commercially, are prepared. There is here no mention of the use of charcoal in manipulating and purifying rare gases. Such a method is, of course, unlikely to be used on a large scale, but knowledge of this kind is undoubtedly useful to those working with these gases. It must be mentioned that there is a chapter on the separation of helium from natural gases.

The liquefaction of hydrogen and of helium are unfortunately left out of account. Admittedly, only the favoured few now handle these liquids, but the technique developed for their production, manipulation and use is of the utmost interest to anyone likely to read a book on the liquefaction of gases.

The production of hydrogen and even of methane from coke oven gas receives great prominence, and cogent arguments are brought forward to show that hydrogen so produced for use in synthetic ammonia plants is an economic proposition. The plant, however, is so complicated that it seems unlikely that it would compete with alternative methods of making hydrogen - nitrogen mixtures of the required composition and purity. The isolation of the constituents of cracked gases in the petroleum industry is described in the last chapter of the book. This is a subject upon which much work will be done, but the paucity of published results makes it difficult for the author to give more than an outline of what has so far been accomplished.

Much of the more recent data and statements of fact given in the book are derived from Russian sources, although a certain amount is culled from the United States. There is, however, often a lack of references to the source of information. This makes it very difficult to assess the value of such statements. In a scientific book of this character, it is not sufficient to say that in the U.S.S.R. such a plant is working at a certain efficiency, unless the figures are backed by reference to a detailed description of the plant in some journal of repute.

The volume is produced in the customary excellent style of the Clarendon Press.

H. W. MELVILLE.

THE MAN OF SCIENCE AS ARISTOCRAT

By H. G. Wells

THE other day I listened with great pleasure to Sir Richard Gregory's Aldred Lecture[1], and admired once again his instinct for bringing together into the most fruitful association, facts and consequences lying far apart, and extracting wide suggestions and new problems from the assemblage. But the readers of NATURE do not need to be reminded that Sir Richard was a brilliant editor so that without any sacrifice of its world-wide scientific usefulness he also made this weekly journal a medium of interpretation and understanding between one type of specialist and another and between specialists in general and the man of general intelligence and broad curiosity outside the ranks of the specialist worker. The Royal Society began as an assembly of curious gentlemen, amateurs all, and how else could it have begun ? It could include Pepys, for example, to his great benefit certainly and maybe to its own.

I find that very relevant to Sir Richard's discussion, and Prof. Hill's stimulating address on scientific co-operation[2] comes in at a different angle to the set of problems Sir Richard has set going in our minds. He gave us no solutions, and it may be there is no simple comprehensive final reply to the questions he had started. Is there a real hard-and-fast difference between discovery and invention, between pure and applied science, between philosophy and science, between the professional and the amateur, between gentlemen and players, between the inventor and the patentee ? One can imagine a sort of preposterous Royal Commission sitting to define the boundaries and calling a fantastic crowd of witnesses. The discussion would slop over into the world of artists and writers and of all who deal in thought and knowledge. Is it within the honour and dignity of a writer to write an advertisement ? Or to write a book pandering to popular sentimentalities he despises ?

But if we admit the boundaries are indefinable, it is still arguable that there are centres to this peripheral vagueness. There are types and groups and individuals, almost completely disinterested in their contribution to human achievement, and there are others whose activities are deliberately directed to gainful research. Again we have another group whose end is neither the good, the true or the beautiful, but a definite practical end. Thinkers unduly influenced perhaps by the materialist interpretation of history have it that every step in invention and discovery has been a response to a very present need. Man had long wanted, to practice agriculture in a methodical manner, and so he took up astronomy ; he wanted to fix the boundaries of his fields in a wide flat plain and so he stretched out his hand into the unknown, and behold ! geometry was there. He wanted to go places and so he leapt upon the hitherto merely edible horse and supplemented its insufficient sturdiness by breeding and the wheel. I put these things from one angle, but one can quite easily turn the point in the other direction. When man rumbled off in his first chariot, was he looking for something practical he needed urgently, or was he just looking for trouble ? No community would have kept and fed an astronomical and geometrical priesthood unless it had fulfilled a vital practical need. But how far the priest created the need he also satisfied is one of those head-spinning questions best dealt with by a gathering of convivial anthropologists after dinner. For the answer to almost all these conflicting questions seems to be : "Well ; to a certain extent—*yes*."

But to push further into the luminous fog into which Sir Richard and Prof. Hill have lured me, and which I find so stimulating that it has kept me awake at nights, it is, I think, possible to define the practical problem to which their thoughts are directed. It is the protection of progress. They both think that human living should be and can be made more abundant and happier by the progress of discovery and invention, and they are agreed that that progress is only possible in an atmosphere of world-wide free expression, publication and exchanges. Free expression is the breath of human hope.

But neither of them stops at that. Sir Richard in particular upsets a whole beehive of notes of interrogation beyond that primary demand. The driving force responsible for the rapidity of human progress in the past century and a half has been, he evidently thinks, discovery. Exploration, fundamental research, discovery, is the root from which the immense wealth of modern invention springs. Lying abed, at nights I have disputed that, but it is true. I thought of the bicycle as an invention that owed nothing to discovery, that might have happened anywhen. The idea of the hobby horse, one might think, is old as the wheel ; a fair road was necessary, but there were good roads in the early empires, and I would not be surprised to find a hobby horse in a Sumerian burial mound, just as one might find a prehistoric glider in Crete. There would have been nothing fundamental in adding a treadle to the hobby horse. The penny-farthing boneshaker was equally open to man, therefore, except—except that that big wheel was impossible, and it was impossible because of the backwardness of metallurgical practice. The 'safety' was still more impossible because of the lack of skill and material for gearing. The invention of the practicable bicycle, like the glider, has had to wait throughout the ages therefore until the fruits of scores of remote explorations and discoveries had filtered down to practical exploitation. It could not have happened earlier than it did, and only as a consequence of that fundamental work.

So that the preservation, multiplication and cultivation of the 'pure' discoverer is the primary solicitude of all of us progressives, and it becomes an inquiry of primary importance to the liberal thinker to reveal what are the political and social circumstances that will produce this type in maximum abundance and satisfactory activity.

Last winter I flew over most of America. I visited a number of universities and among others the great technological organization at Pasadena. I saw the great lens of the Lick Observatory being rubbed slowly to a perfect curvature, and I brought my knowledge of the chromosomes of the fruit-fly up to date with my old friend Prof. T. H. Morgan. The atmosphere was charged with considerable political excitement because of the presidential election, and I found a very curious divergence of opinion between the elder and the younger men of science. The older men had found their opportunity through the endowments provided by rich men, and they seemed to be unable and unwilling to contemplate any other way of sustaining research. Except in social and economic science, the yoke of the patron had been easy to bear, an almost imperceptible weight. The endowment paid its money for distinguished achievement and the man of science had a free hand, and the more he carried himself as a distinguished mental aristocrat, the more he gave satisfaction. But in our world of rapid revolution the very foundations of this conditional security are threatened, and these elder men of science are, so far as my knowledge goes, politically Tories to a man. They have a real and justifiable fear of the State politician, of journalistic denunciation, of a vast paralysing network of control. They do not want to change the rule of the wealthy patrician for that of the political commissar.

This, however, is not the case with the progressive recalcitrant sciences, and among the younger men of science in all departments I found a lively disposition to get on with a new world and to find in an extension of federal activities in the way of research and educational facilities a substitute for the spontaneous and rather incalculable generosity of the now deflated wealthy. I will not take sides here and now. I report what is happening merely to raise the question of how the scientific worker is to adjust his pride and honour to this new and dangerous change in his sustaining conditions.

He may have to face not simply difficulty and poverty but bitter frustration. To do that he will have to set aside any pseudo-modesty that afflicts him. By resolving to become a primary research worker he decides that he is one of a necessary *élite*, an aristocrat in a democratic world. How can he decide that ? If he feels that his research work is better worth while than anything else in the world, then probably it is worth while, and if he does not feel that, he had better turn to something 'with money in it'. He must not wait for a grant or anything, he must go ahead with it, whatever it is. Curie could do that. Think of the poverty of his life throughout, and how he died, and then think of all that the world owes to him. This world to-day is his.

My old friend, York Powell, told me years ago, "Your first duty is to the gift within you. It does not matter whom you offend nor how you sacrifice your popularity. Do the thing that you are impelled to do. Everything else is secondary to that impulsion." What holds good for the writer, holds good for the primary research worker. It is the same problem.

The philosophy for the essential research worker I submit is a stoical aristocracy. I note with interest and a certain cynicism the suggestions of our authors for gratuities and patents. Do any gratuities get to the original discoverers ? I doubt it. Years ago I took up the idea of Diplock's pedrail and applied it to the problem of trench warfare. Diplock was the originating inventor. I described a tank and how it could be used to break an entrenched deadlock, in 1903, in a story called "The Land Ironclads". Years afterwards I discovered that some enterprising gentleman had secured a considerable gratuity as the "inventor" of the tank. His imagination stopped short just where my story stopped short. He had no idea of how to use the tank, and the British Higher Command made an utter mess of the job. It might have decided the war in 1916. I was kept in the dark as to what was going on or possibly I might have broken out with some saving suggestions. Later on, de Gaulle was quite unable to teach the elderly French generals the principles of mechanized warfare, and the Germans last year were the first people to make an intelligent use of the tanks. But anyhow my gratuity (or Diplock's) was intercepted. That is likely to happen constantly. Interception will become an art if gratuities multiply, and I do not see how one can circumvent the 'Smart Alecs' without a tedious amount of litigation and worry that would distract one from one's proper work.

Much the same thing applies to patent rights. I doubt if many patents give any protection to original inventors. There also I have had some slight but edifying experience. I wrote a book about a "time traveller", and about that time the new "instantaneous" photography appeared. Mr. Paul came along to me and we took out a provisional patent that would have made us practically the ground landlords of the entire film industry. We nearly patented films! We did not go on with the patent. Happily. Otherwise we should have found ourselves corruptingly rich, and a heavy incubus on the development of the cinema. It would have been a mere fluke, a lucky anticipation of unsuspected possibilities, a hold-up.

I can't answer for Mr. Paul, but I have no doubt that all that ill-gotten gain would have demoralized and wasted me completely. My egotism would have been inflated. It would have snatched me from honest work and brought out the latent arrogance and detestableness in my nature. I might have become a Press peer. I might have endowed and dominated futile *ad hoc* research. I might have joined the privileged class which can treat men of science and civil servants and the like as though they are Greek slaves. Happily, it did not dawn upon us until too late what a vast commercial opportunity we were missing. Our provisional patent lapsed.

Those particular experiences make me equally sceptical of the effectiveness of the gratuity and the patent. It seems to me that in the end the research worker, the philosopher, the author or the artist must fall back upon his innate conviction of the supreme value of his work. His ultimate resource is pride. With that he must be prepared to sustain himself against adverse conditions. He must do his best always. He must endure the bludgeonings of fate. Those who detect his quality may be able to put laboratories, transport and material at his service, but they must not insult him with offers of prizes and profits and honours, they must fight for that unrestricted freedom of expression without which he is muffled and made ineffective, and the rest lies with him. He has to hold to it and insist that so far as his work goes he is an aristocrat, an angular aristocrat it may be, but the only kind of aristocrat the new world has any use for. It matters very little if he is poor, gauche or shabby. Without any pretence of false modesty he has to bear himself as an aristocrat not only within himself but among his peers, whether they like it or not. He is the key man of the New World.

---

[1] The Royal Society of Arts Aldred Lecture, 1941: "Discovery and Invention", by Sir Richard Gregory, Bt., F.R.S.

DIFFUSE REFLEXION OF X-RAYS

BY G. D. PRESTON,

NATIONAL PHYSICAL LABORATORY

THE diffuse reflexion of X-rays by crystals was the subject of a discussion held by the Royal Society on February 6, when the theoretical and experimental evidence was reviewed by a number of speakers. By way of introduction to the views put forward concerning the origin of diffuse reflexions, a short historical summary of the subject will not be out of place.

The presence of stray reflexions, spots or streaks, is familiar to anyone with experience of taking Laue photographs. In many cases they are due to crystal imperfections, strains, etc., caused in the process of mounting the crystal or in cleaving it to a convenient size for examination. But even after care has been taken to eliminate all such causes, there still remain reflexions the presence of which is not explicable by the usual theory of crystalline diffraction. Such reflexions were first recorded by Friedrich[1] in a Laue photograph of sylvine in which short, faint streaks appeared running radially through the most intense Laue spots; he did not, however, offer any explanation of their presence. Ten years after Friedrich's photograph was published, Faxén[2], as a result of a theoretical investigation, suggested that these streaks were due to the disturbance of the regular geometrical atomic pattern by thermal agitation of the atoms. His work and that of Waller[3] was so complicated that the implications of the theory have lain concealed for some fifteen years beneath a mass of mathematical symbols.

In the interval the attention of experimenters has been focused on the verification of the simpler theories of Darwin[4] and Debye[5], in which the effect of temperature in diminishing the intensity of the normal reflexions was investigated. This

concentration on the X-ray reflexions associated with integral indexes (*hkl*) was natural at a time when the application of the new method to the study of crystal structure opened up such a wide field for research. The very weak background reflexions were rightly regarded as of secondary importance.

Within the last five years, interest in these faint reflexions has been aroused and they have been studied simultaneously in several laboratories. Some of the anomalous reflexions are due to crystal imperfections caused during growth or to the occurrence of a chemical reaction in the solid state. Examples of these two phenomena are to be found in minerals[6] and in metals[7]; in both cases the background reflexions are to be ascribed to minute imperfections in the crystal.

There are, however, background reflexions which are associated with the thermal vibrations of the atoms in the crystal. These are of fundamental importance because they form an integral part of the spectrum of the crystal and cannot be separated from the normal reflexions. It was shown by Preston[8] in 1939 that Laue photographs of aluminium, sodium chloride, magnesium oxide, zinc and diamond had background reflexions which became more intense as the temperature of the crystal was raised. One of these photographs is reproduced in Fig. 1; it was obtained by means of a monochromatic beam of silver $K\alpha$ radiation falling on a single crystal of aluminium at 500° C. perpendicular to a cube face. There ought to be no spots on this photograph because the Bragg condition is not satisfied for any crystal plane; the faint pattern of spots with fourfold symmetry is due to the thermal waves in the crystal. Preston suggested that the pattern was due to the presence in the crystal of small groups, consisting of an atom and its neighbours, which diffracted X-rays more or less independently.

Slightly in advance of Preston's investigation, Laval[9], using the ionization spectrometer and monochromatized copper and molybdenum radiations, carried out an investigation of the background intensity and its variation with temperature, using six different crystalline substances. Unfortunately, the full account of his work was published in a journal not very readily accessible to physicists and has for that reason been overlooked. If we represent the normal spectra of a crystal by the points of which the co-ordinates are integers (*hkl*) in reciprocal space, then we can describe an important part of Laval's work as a study of the distribution of intensity near these points and the determination of surfaces of constant intensity surrounding them.

In the United States, recent interest in background reflexions seems to have originated in the publication of a Laue photograph of rock salt by Wadlund[10]. This picture showed a remarkable system of streaks similar to, but very much more intense than, those recorded by Friedrich in the photograph of sylvine already referred to, but almost certainly arising from the same cause. The matter was taken up from the theoretical side by Zachariasen[11], and the effect is ascribed to the thermal vibrations of the lattice, the formal explanation following the lines of the Faxén-Waller theory.

Sir C. V. Raman[12] and a number of collaborators have described their observations of anomalous reflexions from diamond and other crystals. The new spots are referred to by these authors as 'modified' reflexions, their presence being ascribed to an effect analogous to the Raman effect in the

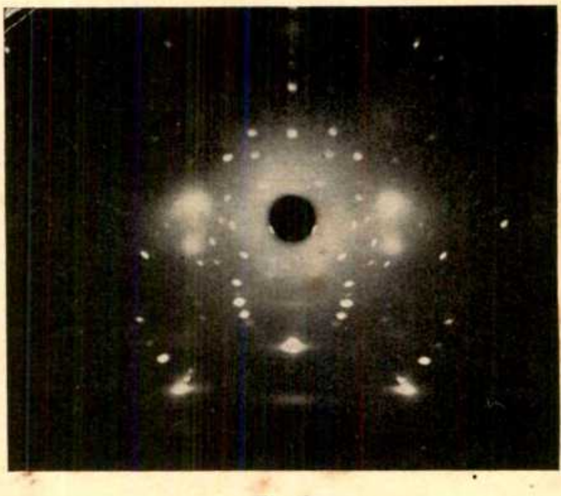

Fig. 2.

Laue photograph of sorbic acid.

Note diffuse spots of different shapes, due to 'layer'- and 'chain'-type planes.

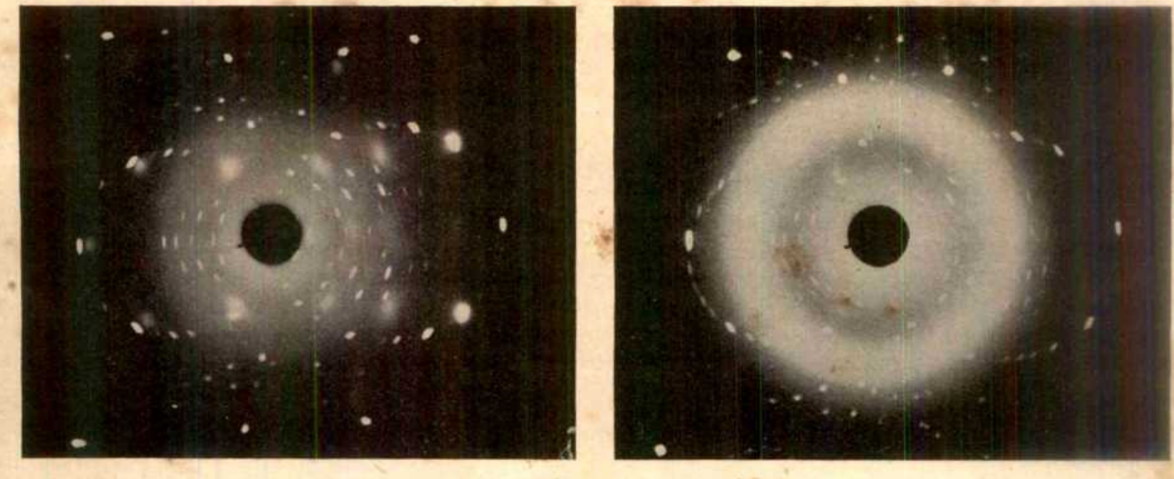

Fig. 3.

LAUE PHOTOGRAPH OF α-RESORCINOL.

(*a*) Showing arrangement of diffuse spots in layer-lines. Crystal enclosed in fine 'Cellophane' tube, at room temperatures. Photographs before and after liquid air experiment are identical.

(*b*) Same orientation and exposure, at liquid air temperatures. Intense diffuse ring due to liquid air stream. Note almost complete disappearance of diffuse spots and improvement of Laue picture.

optical region of the spectrum. The 'modification' implies a change of frequency accompanying diffraction, the change being too small to measure. In essence, Raman's interpretation agrees with that of other workers in ascribing the anomalous spots to the presence of elastic waves in the crystal. It is not at the moment clear whether Raman considers the waves to be due partly to temperature vibrations or solely to excitation by the passage of the X-ray beam through the crystal. The dependence of the intensity of the spots on temperature was, however, demonstrated for sodium nitrate.

The most recent, and much the most comprehensive, study of temperature spots comes from Dr. K. Lonsdale[13], a full account of whose work will appear in the *Proceedings of the Royal Society*. She has obtained a large number of photographic records of the diffuse spot effect, some of which have recently been exhibited at the Royal Institution. Her main conclusions may be briefly summarized as follows :—

(1) The diffuse spots may be seen on X-ray crystal photographs of every kind and measured on the ionization spectrometer. A much longer exposure is generally required than in the case of a Laue photograph. She found it convenient to use the 5-kw. tube of the Davy Faraday Laboratory and sometimes the 50-kw. tube to record the spots.

(2) The diffuse spots are due to the diffraction of the characteristic X-rays, as others have found.

(3) Each diffuse spot lies close to, or in the same position as, the Bragg reflexion from some crystal plane, the indexes of which can be found by a slight rotation of the crystal ; and the spots are found only under conditions in which the corresponding Bragg reflexion can be found by such a rotation. This means that the pattern of diffuse spots corresponds very nearly with the pattern of Bragg spots formed when the crystal is oscillated through a small angle on either side of the position in which the diffuse spots were recorded.

(4) The intensity of a diffuse spot is related to the intensity of the corresponding Bragg reflexion and to its separation from it.

(5) Radial streaks on Laue photographs are generally due to diffuse reflexion of white radiation.

(6) Monochromatic radiation sometimes produces non-radial streaks, notably in the case of benzil. Sometimes patches of diffuse scattering appear and other anomalies not yet explained. 'Layer' and 'chain' structures give diffuse spots differing markedly in shape and in other respects ; the study of these diffuse spot patterns may provide valuable assistance in structure determination (Fig. 2).

(7) The intensity and extent of the diffuse spots are strongly affected by temperature, as Preston and others have shown. They disappear at the temperature of liquid air. As the diffuse spots strengthen, the Laue spots weaken, and vice versa, all the effects being reversible (Fig. 3, *a* and *b*).

(8) Considering the effect in terms of reciprocal space, the diffusely reflecting regions surrounding each reciprocal lattice point are not, in general, spherical, but are extended along certain planes and axes. This is proved by the existence of non-radial streaks and accounts for the small movement of the streaks and diffuse spots when the crystal orientation changes. The configuration of diffuse spots observed in diamond and sylvine demonstrates this and shows that the plane of

diffuse scattering is not always coincident with the plane of incidence.

Besides arriving at these general conclusions, Mrs. Lonsdale has considered, in the paper referred to, the relations of the intensity, shape, size, position and persistence of the spots to the nature, structure, perfection, orientation and temperature of the crystal, to the radiation used and to the conditions of photography.

Sir William Bragg[14] has analysed the pattern of diffuse spots produced by sylvine and has found that they correspond to the diffraction effects to be expected from a simple cube of eight atoms. He points out that in all cases hitherto examined the diffuse spot pattern agrees closely with the true diffraction pattern of the crystal under monochromatic radiation, as given by the formula for intensity :—

$$I = (\Sigma m_1 m_2 \cos {}_1\varphi_2)\,\frac{\sin^2 p\varphi_a/2}{\sin^2\varphi_a/2}\cdot\frac{\sin^2 q\varphi_b/2}{\sin^2\varphi_b/2}\cdot\frac{\sin^2 r\varphi_c/2}{\sin^2\varphi_c/2}$$

In this formula m_1 and m_2 represent the scattering powers of any two centres in the unit cell, and ${}_1\varphi_2$ represents the difference in phase of the waves which they scatter, each centre to be reckoned in conjunction with itself as well as with all the others. The quantities φ_a, φ_b, φ_c, are the differences in phase associated with the three principal translations of the cell, and p, q, r, the number of times that the respective translations are repeated.

If p, q, r, are large numbers, the intensity will be relatively extremely small unless the three denominators are simultaneously very close to zero. This complete coincidence requires the special disposition of the crystal with respect to the incident ray which is prescribed by Bragg's law. But if p, q, r, are small, as in the case of the small groups suggested by Preston, there will be a regular pattern which might be visible if there were enough groups, and would possess, in the main at least, all the properties so far found to be possessed by the diffuse spot pattern, for example, the connexion with the oscillation photograph. The effect of temperature might be due to a change in the number of small groups, as Preston has suggested. The principal translations can be deduced from the pattern as Sir William Bragg has shown for potassium and sodium chlorides, calcite and benzil.

Sir Lawrence Bragg considers Preston's idea of diffraction by small groups of atoms does not fully account for the phenomena observed, and that this is so because it leaves out of account the fact that the groups form part of an extended crystal structure and so cannot be regarded as scattering independently. The observed positions of the diffuse spots obtained with monochromatic light may be explained by saying that diffraction takes place when the phase of reflexion passes *near* a point of the reciprocal lattice, and is not restricted to the special condition of passing exactly through it. This is merely an alternative way of expressing Preston's condition in reciprocal notation. Now, if a crystal is broken up into a number of small independent units, roughly parallel, the points of the reciprocal lattice are smeared out, and the intersection of this by the sphere of reflexion gives diffuse spots ; hence the success of the 'group' idea in accounting for Preston's original photographs and the much more complex ones obtained by Mrs. Lonsdale and analysed by Sir William Bragg. This cannot be the complete explanation, however, because along with the diffuse Preston spots one obtained *sharp* Laue spots and *sharp* spots in a rotation photograph. The whole phenomenon must be described by saying that at each point of the reciprocal lattice there is a sharp central spot surrounded by a diffuse cloud ; both spot and cloud must be ascribed to the same crystal, and both must be explained simultaneously.

The distortion of an extended lattice by heat-waves provides the explanation. The superposition of a periodic heat-wave of wave number n upon a lattice of wave number N produces periodic components in the crystal structure of wave numbers $N \pm n$, $2N \pm n$, $3N \pm n$, etc. Corresponding X-ray reflexions can thus be obtained, and appear as a pair of 'ghosts' on either side of the main reflexion. The whole complex of heat vibrations exactly fills the reciprocal lattice space with these ghosts, and it can be shown that the ghosts nearest to the reciprocal lattice points are the strongest, because the longest heat-waves displace the atom to the greatest extent. Hence the reciprocal lattice at low temperatures is a series of discrete points, whereas at high temperatures a cloud of ghosts fills all the space and is strongest near the points of the lattice, which latter diminish in strength but remain sharp. This is precisely what is observed. If the crystal effectively broke up into groups of atoms, sharp Laue or rotation spots would no longer exist ; their persistence at high temperatures shows that we must take the phase relationship right through the crystal into account.

That the small groups which apparently render a simple and accurate account of the observed spots do not appear explicitly in the formal theory does, at first sight, throw very serious doubt on their existence. Darwin, however, suggests that the fact of their absence from the analysis is not in itself sufficient ground for dismissing the idea as false. To illustrate this point, he draws an analogy with the analysis of the rise and fall of the tide in an estuary. Owing to local conditions there might, for example, be a long period at low water when the level did not change appreciably. The Fourier analysis would predict this feature of the tidal change quite accurately, but would not indicate the precise physical cause (the draining of a large expanse of sandy foreshore) which produces the effect. In the same way the Fourier analysis of the thermal disturbance of the crystal would predict the intensity of X-ray reflexion correctly, but, as information concerning the phases is lacking, the presence of groups could not be predicted.

In discussing the theoretical problem offered by the experiments on background reflexions on Laue photographs, Prof. Max Born inquired whether the phenomena can be explained by the well-established theory of scattering or whether new assumptions are necessary. He observed that the fact that Sir William Bragg's formula represents the position of the spots so well, suggests that it should appear as a result of a theory more satisfactory formally, than the assumed presence of small groups of atoms. It seems that an improved theory of the effect of thermal vibrations should provide an adequate explanation of the observations. The important fact emerges that just as the Laue spots, or Bragg reflexions, determine the geometry of the lattice, so the background pattern is a complete image of the main features of the dynamics of the lattice.

The observation of effects similar to those discussed above has been recorded by Charlesby, Finch and Wilman[15] using the method of electron diffraction. Their experiments show that for molecular crystals, such as anthracene, the thermal vibrations of the lattice produce a background pattern. The effect is somewhat similar to that of a vapour in which all the molecules are oriented and produce a pattern which should reflect the symmetry of the molecule. It appears that the X-ray effect is not identical with that observed with electrons, for some of Mrs. Lonsdale's photographs of benzil do not produce a pattern characteristic of the benzene ring when the crystal is examined in a suitable orientation.

The whole subject of background reflexions is evidently one of very considerable interest and no little complexity; further investigation, both theoretical and experimental, should provide information regarding the structural imperfection of crystals, whether of thermal or other origin.

In preparing this article I have been greatly helped by Sir William Bragg, Mrs. Lonsdale and Sir Lawrence Bragg. It is with pleasure that I acknowledge my debt to them.

CENTENARY OF THE PHARMACEUTICAL SOCIETY

THE centenary of the foundation of the Pharmaceutical Society of Great Britain occurred on April 15, 1941. Thirty years ago, congratulating the Society on its seventieth anniversary, Nature observed that it was "an event of considerable interest, which is not wholly confined to those who practise the art of pharmacy". The same may be said, with emphasis, on the occasion of the centenary. It is no small thing even for an institution to survive ten decades. The mere fact is proof of its stamina and its usefulness; a hundred years on and how many fall by the way. The Pharmaceutical Society has gone from strength to strength, and it may be said to-day that its place among the nation's useful foundations was never more secure and its service to the State never more highly esteemed or more needed.

Just as among individuals, a man often owes his virility and his good purpose in life to his parents, so does the Pharmaceutical Society owe much to the scholarly Quaker, William Allen, F.R.S., who has been justly called its father, and was its first president. He was the owner of a chemist's shop in Plough Court, Lombard Street, London, and it seems strange that in the days when the practice of pharmacy was in the hands of a heterogeneous mass of tradespeople, most of whom were without scientific knowledge and but poorly equipped with the materials of their business, there should be found among them a man of high scientific attainments, a fellow of the Royal Society, one of the founders of the Askesian Society for practical research, who had lectured at the Royal Institution and at Guy's Hospital. Besides all these things, William Allen was confidential adviser to Edward, Duke of Kent, the father of Queen Victoria ; it was on the advice of this City druggist that the Duke consented to place his property in the hands of trustees, the consent being given on condition that William Allen was one of them.

There is little wonder, then, that those members of the craft of pharmacy who were sufficiently enlightened to see the need of organization chose this outstanding personality as their leader ; and the Society having been established by a resolution passed at a meeting held at a Strand tavern on April 15, 1841, it is not surprising that with such a man at its head the infant body put down education as the first item on its programme. Before the end of the first year a course of lectures had begun at 17 Bloomsbury Square, which was then, as it is now, the Society's headquarters. The policy was initiated of securing as lecturers men of high standing in their particular branches of science, a policy which has been maintained ever since. A year later, the School of Pharmacy—now recognized as a school of the University of London—was established, and soon a chemical laboratory, the first of its kind in Great Britain and the equal of those existing at that time in Germany and France, was set up. A system of examination was instituted, and in due course there was available to physicians the services of a new class of craftsmen well equipped by training and education for the purpose of their calling.

It was not until the Pharmacy Act, 1852, was passed that statutory recognition was given to those who passed the examinations, and not until 1868 that the Society succeeded in impressing upon Parliament that the best way of protecting the public from the dangers inherent in the mishandling of poisons was to reserve the retail sale of these substances to trained vendors. Even to this day, the practice of pharmacy has never been restricted by legislation, but fortunately the law now furnishes means by which the public can distinguish a pharmacy which is under the management of a qualified person from a shop which is not so managed.

Space does not permit extended references to the valuable work done by the Society in connexion with the production of the "British Pharmacopœia", or to many of its other activities, notably its scientific meetings, directed to the spreading of knowledge among its members. The quality and advanced nature of the research work now undertaken in the College of Pharmacy is seen in recent reports from its several departments. Thus in the pharmaceutical chemistry laboratories investigations have been made with the view of bringing recent developments in our knowledge of carbohydrates into the domain of medical substances by work on specific sugars in immunological work, and promising work has been done in connexion with œstrogens. Investigations made in the Department of Nutrition have shown that the pigeon test still appears to be the least accurate of the biological methods for the determination of the vitamins. In the Department of Pharmaceutics, research work has been directed to the investigation of pharmaceutical apparatus with a view to improvement in design, particularly in respect of small-scale types. In the Department of Pharmacognosy detailed studies have been made of the flowers of the belladonna plant, and examinations have been made of Jamaican and Surinam quassia. Work done in the Department of Pharmacology comes under such headings as the assay of cortical hormone, the pharmacologically active substances liberated by adreginic nerves, the pharmacology of antipyretics of the aromatic amine series, the mechanism of porphyrin excretion, the toxicity of certain bactericides, the pharmacology of eucalyptus oil and the chemical assay of powdered ergot.

The above is but a small selection of the subjects which have occupied the attention of research workers of the Pharmaceutical Society, but it serves to show how truly it has endeavoured to fulfil the obligations placed upon it by the Royal Charter of incorporation to advance the knowledge upon which the art of pharmacy is based. It is a far cry from 1841 to 1941, when one reflects upon the state of pharmacy as it was when the Society was founded and as it is to-day. There has been, of course, a slowing down of research activities since the outbreak of war, mainly because of the reduction in staff. Prof. J. H. Gaddum, director of the Pharmacological Laboratories, undertook an appointment under the Government for the duration of the War, and other members of the Society's staff have also been called to different duties. Nevertheless, useful research work continues to be done in the several departments.

Sufficient has been said to show that the Pharmaceutical Society of Great Britain well merits the congratulations it has received not only from kindred institutions in other countries, but especially from the bodies representative of the medical profession, which recognizes that the debt it owes to pharmacy is a debt owed to the Society.

OBITUARIES

Dr. Eugene Dubois

Dr. Eugene Dubois who, exactly half a century ago, discovered in Java the fossil remains of that strange being which he regarded as transitional between ape to man and to which he gave the name *Pithecanthropus erectus*, died at his home in Haarlem, Holland, on December 16, 1940. The discovery of the most famous of missing links was announced to the world by a monograph published in Batavia in 1894 and entitled "Pithecanthropus erectus, eine Übergangsform". No single discovery in the realm of dead things has given rise to such a voluminous literature, to so many animated discussions or to so many divergent opinions. There are not so many alive now who remember the arrival of Dubois in England in the autumn of 1895, and saw with their own eyes the material evidence of man's evolutionary past which he had just brought back from Java, and took part in the debates which the discovery aroused. Right to the end of his life Dubois maintained that the being he had unearthed was neither man nor ape, but represented a stage which marks the transition from ape to man. Some of his Continental critics regarded Pithecanthropus as a gigantic gibbon; others gave the thigh bone to an extinct form of man and the skull cap to an extinct form of ape. British anatomists, on the other hand, took the view that Pithecanthropus was a hominid—an early form of man.

In 1898 Dubois again came to Great Britain, to attend the Fourth International Zoological Congress, held in Cambridge. He, the late Sir Grafton Elliot Smith and I were guests of Dr. W. L. H. Duckworth at Jesus College. By this time Dr. Dubois had succeeded in extracting from the skull cap the stony matrix which had filled it and had taken from its interior a cast reflecting the features of the Pithecanthropoid brain. A glimpse by the expert eye of Elliot Smith revealed to him features in the brain which were altogether human; it was a very early human stage which had been discovered. This verdict was confirmed by the Pithecanthropoid family unearthed in the Trinil formations of Java by Dr. Koenigswald during 1936–39[1]. There was much doubt, too, as regards the geological horizon to which Pithecanthropus should be assigned. Dubois favoured a late Pliocene date; the consensus of opinion now is that the date is early Pleistocene, which makes Pithecanthropus a contemporary of Peking man in China and of Piltdown man in England.

In 1925 I gave the following account of Dr. Dubois[2]: "If Dr. Eugene Dubois had been born in the 16th century his spirit of adventure would have found its outlet on the Spanish Main, but being added to the population of Holland in the latter half of the 19th century, when Darwinian ideas were spreading across Europe, he went in search of the 'missing link'. Having finished a training in science and in medicine at the University of Amsterdam in 1888, he became a military surgeon, choosing Java for his service. Before setting out for that island, he promised his fellow students, in all seriousness, to bring home the missing link".

This statement brought me a long letter from Dr. Dubois giving several important and desirable details relating to earlier years of his career, details which will become of increasing interest as years go by. The greater part of this letter is reproduced here in his own English:

Haarlem,
2nd April, 1925.

"Let me express my gratitude for the personal kind note on the discover of the Wadjak Man and Pithecanthropus. At the same time I beg leave to correct some personal statements.

"It was not a spirit of adventure but of scientific reasoning (see a paper in the 'Natuurkundig Tijdschrift voor Nederlandsch-Inde" of April 1888) that pithecoid human forms should be expected in pleistocene or pliocene deposits of the Malayan Archipelago, that induced me to undertake palæontological researches in that archipelago. Before I went to Sumatra (where I expected to make excavations in the many caves of the Padang high lands) in 1887, I had been, during seven years[3], Max Fürbringer's assistant and pro-sector, finally lecturer on Anatomy at the University of Amsterdam. . . . My purely scientific work had been chiefly of comparative anatomy, expecially on the larynx. . . .

"I did not promise my fellow students, in all seriousness, to bring home the 'missing link', but I did tell Prof. Max Fürbringer and Max Weber, my motives why I preferred to give up a certain and beautiful anatomical career for an uncertain one as a field paleontologist, the only way giving access to the latter being that of engaging as a military surgeon in the Neth.-Indian army.

"The paper in the 'Natuurk. Tijdschr.' and some paleontological results of excavations of caves in Sumatra, then induced the Ned.-Ind. Government to charge me officially with *paleontological researches in the pleistocene and pliocene deposits of Sumatra and Java*. From these I brought home a collection at least five times as large as that of the Selenka expedition (1906). I collected also in the Siwalik Hills.

"Pithecanthropus was not found in the 'Hell' of Java, but near that 'Hell', this being the garrison town of Ngaur, in the neighbourhood of Trinil, owing its name of 'Hell' to the circumstance that it was in former times a military convict settlement. . . . In 1898 I was appointed as professor of Geology and Paleontology at the University of Amsterdam."[4]

On returning to Europe in 1895 Dr. Dubois placed only a little of his goods in his 'shop-window'; right on to the end of his life he fetched surprise packets from his back-shop. In 1920 he produced the Wadjak fossil skulls, although he had found them before Pithecanthropus came to light. It was the publication of a description of a fossil skull found in Australia that made him release the Wadjak specimens—which also had Australoid characters. In 1924 he at last published excellent illustrations of the brain cast of Pithecanthropus and also produced a piece of a fossil mandible which he had found in 1890 and now attributed to Pithecanthropus. In 1932 he produced fragments of three more thigh bones of Pithecanthropus.

The cemetery of fossil man which was discovered and exploited by Dr. Dubois in Java has proved to be rich beyond any other in every respect—rich in actual numbers and in types which preserve details of the sequence of humanity that has flitted across the time stage of Java these million of years past. The series begins as ape-men and ends in the aboriginal type of modern Australia. Only in this Australo-Malayan part of the world is the evolutionary history of man known with any degree of fullness[5], and for this we are chiefly indebted to Dr. Eugene Dubois.

A. Keith.

[2] "Antiquity of Man", Second Edition, p. 438.

[3] Dr. Dubois was above medium stature, and although full-bodied, carried himself rather rigidly erect. When in England in 1895 he seemed to be under thirty years of age; from the above statement one infers he must have been born about 1858.

[4] This letter, although it contains further interesting details, is too long to give in full; the original is to be added to the library of the Royal College of Surgeons, (London, W.C.2).

Sir Hugh Murray, C.I.E., C.B.E.

Sir Hugh Murray died at Nunton Cottage, Bodenham, Salisbury, on February 9. For more than fifty years Hugh Murray was connected with and played an active part in the development of forestry and forestry administration in India and Great Britain; both Bombay and England will long remember him and his delightful personality. Murray was born on April 27, 1861. He was educated at Trent College and took his forestry training on the Continent. He joined the Indian Forest Service in 1882, being appointed to the Bombay Presidency.

As a district forest officer, Murray acquired the reputation of being a hard-working and tactful officer, and this recognition was fully maintained when he reached administrative rank in the Presidency. During the twenty-nine years of his service there were some very difficult forestry problems bearing upon the habits and customs of the agricultural population in Bombay which came up for, if not solution, at any rate settlement for the time being. As he rose in seniority Murray was able to give valuable advice in this direction; especially when he occupied the position of Senior Conservator in the Presidency and Additional Member of the Provincial Legislature. He retired from the Indian Service in 1911.

Soon after the outbreak of the War of 1914–1918, Murray was called into the War Office to advise on the then urgent and totally new question of obtaining timber supplies under war conditions. For three years he was thus occupied, becoming deputy controller of timber supplies in 1917.

The Forestry Commission was inaugurated in 1920 as a result of the Parliamentary Bill of 1919. A number of commissioners were appointed, and a technical assistant commissioner for England and Wales and a second for Scotland. Murray was appointed to the English post, and a better choice at that time could probably not have been made, for senior trained foresters with ripe administrative experience were few in number. His chief work was connected with the acquisition of land for the new State forests, and in this he displayed great ability. He was equally interested in the planting work then being started on a large scale and in the research inaugurated at this period. After four years Murray was appointed a forestry commissioner, thereby strengthening the technical position of the Commission. He remained a commissioner until 1934, when he finally retired.

He married, first, Gwendoline Mabel Langridge and had a son; and secondly, Dorothy Christine, daughter of the Right Hon. Sir William Mather, and had a son and daughter. E. P. Stebbing.

Mr. J. Picken

Mr. James Picken, one of the alkali inspectors in the service of the Ministry of Health, died suddenly on February 17, aged forty-six. After a period of service with the Royal Garrison Artillery in France, Mr. Picken took his degree at the University of Glasgow, and was afterwards for some years in charge of the Glasgow Corporation's chemical works at Dawsholme and Provan. He received his appointment as one of H.M. inspectors of alkali works in 1924, and from that time had been in charge of the Sheffield district, where his unfailing tact and courtesy, together with the efficient but sympathetic manner in which he carried out his duties, had earned him the respect and affection of all with whom he came into contact.

We regret to announce the following deaths:

Dr. Annie J. Cannon, assistant in the Harvard College Observatory during 1897–1911, and curator of astronomical photographs since 1911, aged seventy-seven.

Dr. David Forsyth, an authority on the diseases of children, on April 10, aged sixty-three.

Sir Nigel Gresley, chief mechanical engineer of the London and North-Eastern Railway, on April 5, aged seventy-six.

Prof. K. N. Konstantinovich, director of the Moscow Institute of Experimental Biology and formerly director of the Central Station of Genetics, aged sixty-nine.

Mr. J. C-S. McDouall, O.B.E., formerly director of Medical Sanitary Services, Sierra Leone, on March 25.

Prof. Carlos G. Malbran, professor of bacteriology in the University of Buenos Aires.

Sir Albert Seward, F.R.S., professor of botany in the University of Cambridge during 1906–36, on April 11, aged seventy-seven.

Prof. Roy B. Smith, emeritus professor of chemistry in Colgate University, aged sixty-five.

NEWS AND VIEWS

Prof. Frank Schlesinger

Prof. Frank Schlesinger, who is shortly retiring from the directorship of the Yale University Observatory, is the doyen of American astronomers. His work has been concerned mainly with astrometry, and has been characterized by originality, economy of effort and high precision. As director of the Allegheny Observatory, he used the 30-inch Thaw refractor for the determination of stellar parallaxes. From a masterly discussion of the observations and of the various sources of error, he laid down the methods to be followed to ensure the greatest attainable accuracy. These methods have been adopted at other observatories and have led during the past quarter of a century to a great development in the knowledge of stellar distances. After Schlesinger's appointment as director of the Yale University Observatory, he decided to erect a 26-inch refractor in South Africa to determine the distances of southern stars. This telescope was erected in the grounds of the University of the Witwatersrand, Johannesburg, for this specific programme; and for economy in cost, it is mounted in a meridian building, which restricts its movement to a few degrees on either side of the meridian. Intensive observations with this telescope, in conjunction with those at the Cape Observatory, have made the knowledge of the distances of southern stars almost as complete as for northern stars.

Schlesinger has also been the pioneer in the determination of stellar positions with wide-angle lenses, covering fields up to 100 square degrees, in contrast to the 4 square degrees of the Carte-du-Ciel plates. This has enabled visual observations with meridian instruments to be restricted to the brighter stars and effects a great economy in time in photography at the telescope. Methods of measurement and reduction have been carefully planned to secure the greatest economy of effort. Photographs taken with a camera attached to the telescope at Johannesburg have been measured and reduced in New Haven and, with only a small staff, star catalogues have been produced at a surprising rate. Two compilations, the "Catalogue of Stellar Parallaxes", in which all determinations have been combined with appropriate weights and their systematic errors investigated, and the "Bright Star Catalogue", have proved invaluable for reference purposes. Prof. Schlesinger's sound judgment, sane outlook and wise counsel have given him an outstanding position not only among American men of science but also in international astronomy, and were fittingly recognized by his election as president for 1934–35 of the International Astronomical Union.

Honorary Degrees at Bristol

In his capacity of Chancellor of the University of Bristol, Mr. Winston Churchill attended a Congregation on April 12 for the conferment of the honorary degree of Doctor of Laws on Mr. John G. Winant, the American Ambassador, Mr. Menzies, Prime Minister of Australia, and (in absence) on Dr. J. B. Conant, president of Harvard University. Referring to the honorary graduates, Mr. Churchill said: "Through him [Mr. Winant] and other distinguished representatives who are with us to-day . . . we make another tie with the illustrious President of the United States, and with the representatives of that vast community at a time when great matters of consequence to all the world are being resolved. . . . In Dr. Conant we have a figure, widely and deeply respected throughout the United States, and particularly among the youth who attend Harvard University, holding up a clear beacon light for young men of honour and courage." Mr. Menzies, he said, has brought with him the strong assurance of the democracy of the Commonwealth that they with us will go through this long, fierce, dire struggle to the bitter end.

Speaking of the occasion as one of rare and exceptional character because the visitors to whom they were showing honours and courtesies are playing an important part in the universal drama which is unfolding, Mr. Churchill said, "Here we gather in academic robes and go through ceremonials and repeat formulas—here in battered Bristol, with the scars of new attacks upon it. Many of those here to-day have been all night at their posts and all have been under the fire of the enemy, under heavy and protracted bombardment. That you should gather in this way is a mark of fortitude and phlegm, of a courage and detachment from material affairs worthy of all that we have learned to believe of ancient Rome or of modern Greece."

Yugoslav Fauna and Flora

The extension of war into Yugoslav territory takes it into an area of the south-eastern Europe fauna and flora which had only begun to be properly explored by biologists within modern times. The British Museum expedition of 1937 collected four species of Clitellus (susliks or gophers) in Yugoslavia (*Annals and Mag. of Nat. Hist.*, May 1940), two of which were new to science, *Clitellus c. karamani* (named in honour of Dr. Stanka Karaman, explorer of Macedonian fauna), from Karadjica Mountains, Macedonia, and *Clitellus c. laskeri* (named after Prof. V. Laskarer, of the University of Belgrade). Slovenia contains abundant chamois, red and roe deer, bear, wild boar and even lynx, while its avi-fauna includes capercaillie and stone partridge, mostly protected by the 1931 game laws. Spoonbills nest abundantly on the Obekska Bara bird reservation near Belgrade. In the Knez Mihaileva region buzzards and eagles are still well established, while magpies and jays from the Belgrade suburbs have frequently been observed passing over the city.

Flights of wild geese and wild duck, the former coming from the great Hungarian marshes, are frequent sights at the time of hunter's moon. Insect life includes a wealth of butterflies and the curious Yugoslav tiger moth, *Cymbaciophora pudica*, which produces a loud squeaking or clattering noise by its wings in flight. The caves of Dalmatia and Carinthia have long interested naturalists for their blind olm or cave newt, *Proteus anguineus*. The flora is rich in alpine flowers of great beauty. Pančic wrote a useful "Flora of Serbia", and recently Hayek compiled a new Balkan flora. It is an irony that one of its most recent students was Dr. Giuseppi, the Italian botanist and member of the Alpine Club. On his 1930 visit he found *Geranium subcaulescens* on Mount Koprevnia and *Saxifraga montegrina*, receiving the award of merit of the Royal Horticultural Society when introducing the former to British gardens. On Mount Cristen he found *Ranunculus creatus*, and in 1931 on Kerast he found *R. Wettsteisii* and *Ardrosance Hedreantha*, on Ljuetia, *Viola Grisebachiana*. W. B. Turrill, of Kew, also studied the Balkan flora during the War of 1914–18 and three times since. Good herbaria existed at Belgrade, Sofia and Trieste. Tournefort, Sibthorp, Clark, D'Urville and Grisebach collected in the area, which has a flora of some 6,500 species.

International Relations and Federalism

THE February 1941 issue of *Union*, the monthly forum of the New Commonwealth Society, includes a number of articles on post-war reconstruction and the development of international relations. Mr. Duncan Hall, in an address on "What are the hopes of Lasting Peace ?" asserts that only by a scientific understanding of the dynamic forces of human nature and human society, by a realistic education and a wise leadership, can we hope to speed up man's progress towards a lasting peace, based on the supremacy of reason and conscience. The problem is far more than one of finding the right institutions and making economic adjustments. It is essentially a problem of how to control the human forces, how to prevent uneven domestication, how to safeguard against mob situations that break down the conscience and reason of the individual and let loose his instinctive forces. Writing on "The Outline of a Long-Term Economic Plan", Mr. W. L. Fairweather urges that the task ahead of us is to raise the level of consumption all over the world, and that many of the controls necessary in war will be extended and developed and remain as a permanent feature of the economic system. Mr. Channing-Pearce's address to the Oxford Branch of Federal Union on January 4 on "The Federal Faith" is included, with its conception of federation as concerned not only with politics but also with sociology and economics.

The Wilkes Centenary

THE centenary of the Wilkes Exploring Expedition of the United States Navy, 1838–1842, was marked by a symposium on American polar exploration organized by the American Philosophical Society in February of last year. The papers read on that occasion are now published (*Proc. American Phil. Soc.*, **82**, No. 5) and include some valuable contributions to polar geography. The expedition is best remembered for its antarctic landfalls, which have since been the subject of much controversy but mainly have been confirmed. The expedition had, however, a practical bias, actuated by the considerable American whaling industry in the Pacific at that time, and the scientific side was not too strong though valuable results were obtained not only in the antarctic but also in many surveys in Pacific islands and numerous biological collections. The greater part of the results were published by the authority of Congress, but the edition was small and many of the volumes are rare. In the present publication the history of the expedition and the story of the struggle to get the reports published are fully traced and there are valuable bibliographical records.

A most useful paper deals fully with the fishes collected by the expedition, a report which has not previously appeared. This is by Mr. H. W. Fowler. Another paper, by Commander F. W. Reichelder, discusses the contributions of the expedition to magnetism, gravity and meteorology. Prof. W. M. Hobbs treats of the geographical discoveries. Another series of papers deals with other aspects of American polar work. Of these may be noted one by Mr. W. E. Ekblaw on the arctic discoveries of De Haven, Kane and Hall and another by Mr. H. J. Lee on Peary's journeys in North Greenland. Two valuable and original papers are those by Prof. L. M. Could on the glaciers of Antarctica, which surveys all the glaciological problems, and one by Mr. V. Stefansson in which, with his customary bold conception, he advocates a ten-year programme of arctic studies to be centred in a number of stations, most of them on the pack-ice, to be established and maintained by air.

Early Man in Virginia

FOR some little time evidence has been accumulating which points to Bedford County, in south-western Virginia, as a place of early settlement of stone-using aboriginal tribes of nomadic hunters. During proto-historic and early historic times, Siouian and Iroquoian tribes appear to have lived within the present bounds of the county ; while the Cherokee in the earlier half of the nineteenth century still retained the memory of an old tradition that a Cherokee village once stood near the twin Peaks of Otter in the north-west of the county where it is crossed by the Blue Ridge. These peaks were formerly thought to be possibly among the highest of the northern continent ; and it is believed that the region around had been occupied for many centuries by a succession of tribes of different stocks, ever since the time when nomadic bands first entered the wilderness. This belief has now received the support of recent discovery in the form of stone implements of an early type on a site, now known as the Mons site, which was revealed early in 1940 in road-making operations in the vicinity of the Peaks of Otter. In a description of the site and finds by David I.

Bushnell, jun. (*Smithsonian Miscell. Collect.*, **99**, 15; 1940) it is recorded that stone artefacts, fragments of steatite vessels and small bits of earthenware were exposed during removal of the top soil. Although some specimens were obviously older than others, no determination of age was possible in the absence of stratification. Nor was it possible to mark the extent of the settlement; but quantities of flakes of various types and fractured pebbles indicated the existence of a workshop. The types of artefact included flake-knives and scrapers, projectile points, several forms of edged implements, axe-like implements, hammerstones and possibly pestles. Two Folsom points have been found on the site mingled with the other material.

This is the first occasion, so far as is known, on which the Folsom point has been found in the eastern States in association with other material or on a settlement site, though Folsom points of the Eastern type, which is not identical in all details with that of the south-western States, have been found sporadically in Virginia and elsewhere. The specimens from the Mons site may be regarded as clinching the argument for an eastward extension of Folsom man associated with an evolving industry, conditioned at times by the necessary employment of a refractory material. That the nature of the stone and not ignorance of the characteristic technique is responsible for the absence of the groove in the chert points from the Mons site is shown by the occurrence there of flakes of jasper, such as would be produced in the manufacture of a typical point of that material, which has been found no more than two miles away.

Agricultural System of the Argentine

THE Imperial Bureau of Pastures and Forage Crops, Aberystwyth, has recently published a bulletin on "The Grasslands of the Argentine and Patagonia" (*Bull.* 30. 2*s.* 9*d.*). The author, W. Davis, has himself made an extensive tour of South America, and his account contains much of interest to the general reader as well as to the grassland specialist. Patagonia is chiefly a sheep ranching country, carrying a vegetation of open tussock grassland in the south, and shrub steppe in the central and northern regions. In the Argentine proper, cattle are more important than sheep and, compared with Patagonia, farming is much more intensive. As a result, the native flora has been largely replaced by exotic species of both grasses and legumes.

One of the most interesting features of this intensive farming is the practice of fattening cattle on lucerne in the La Plata region. The temporary ley is the basis of this form of husbandry, together with the use of cereal crops for out-of-season grazing. Much of the land is held by companies and by individuals who are fattening cattle on large holdings (*Estancias*), and is worked on a share farming system. The farmer cultivates and crops the land, sharing the crop with the landowner on an agreed basis. After a run of cereal crops, it is a condition that the land must be laid down to lucerne, at which juncture the farmer moves on to another holding, and the owner receives his land back carrying the requisite crop for his cattle. It is suggested that a modification of this system might profitably be used in parts of Great Britain. The bulletin concludes with an interesting account of the *frigorifico* at Buenos Aires, where killing of the cattle and utilization of every part of the carcasses are carried out in a most efficient manner.

The Nigerian Forester

THE idea of issuing a journal in Nigeria or for West Africa generally on the lines of the *Indian Forester* was mooted several years ago. Last year saw a realization when two numbers of the *Nigerian Forester* were published in July and November. The editor appears to be somewhat diffident about the appearance of a new publication in war-time. The paper devoted to its publication, however, is very far from being wasted, for some of the articles appearing in the first number are both timely and of interest. With one exception, where the exotic trees of the Cameroons are dealt with by D. R. Rosevear, the articles in the first number deal with either Northern or Southern Nigeria and present a wide variety of problems. In the second number, in addition to some general articles such as "Termites and Soil Fertility", "Work in the Veterinary Department, Nigeria", and "Some Applications of Grassland Ecology", subjects such as "The Gold Coast Timber Industry" and "First Impressions of Forestry in Sierra Leone" are dealt with.

Perhaps of wider interest, though somewhat sad, is the announcement that the *Nigerian Forester* is to be replaced by another publication on the same lines but with a wider purview, entitled *Farm and Forest*. This publication will be devoted to the discussion of land use problems in West Africa from the point of view not only of the forester but also of agricultural, veterinary and other workers interested in the manifold aspects of rural economy. It will thus have a wider public and should get over the financial difficulty which a specialized journal issued by a small Government Department always has to face.

Underground Gasification of Coal in the U.S.S.R.

THE "Russia Today" Press Service has issued a statement of the progress of work on this problem during the last few years in the U.S.S.R. It is recalled that Mendeléeff envisaged this method of fuel treatment, and about a generation ago Sir William Ramsay suggested the initiation of research thereon in Great Britain. In the U.S.S.R., however, the first practical work was begun in 1933 on the gasification of the coal in the seam. This is reached by two shafts connected by a tunnel cut through the seam itself. The coal is gasified by a blast of air or oxygen and steam blown down one shaft while the hot gas produced is collected from the up-cast shaft. This method necessitates the labour of miners to sink the shafts and to tunnel the seam before gasification can begin. In a new installation in the Donetz coalfield, the seam will be reached by bore holes so that no underground work will be necessary. Last

November a plant, it is said, started operation on an industrial scale in the Moscow coal area to supply gas for chemical manufacture. A new installation in the Donetz coal field is expected to dispense with the services of five hundred miners. Where oxygen is employed to enrich the blast and so produce a gas of higher calorific value and lower nitrogen content, the cost of the separation of oxygen from air largely determines the economics of the process. It is claimed that Prof. P. L. Kapitza has designed a plant for air separation which marks an advance in technical efficiency.

At a time like the present, it is important to picture the possible consequences of these developments. If successful, they would mean the reduction or abolition of one of the most arduous of human efforts, but only if coke could be dispensed with. Coal, once gasified and converted into a mixture of carbon monoxide and hydrogen, becomes not merely a flexible source of heat and power, but also a starting point for the most diverse chemical syntheses. In a highly industrialized country like Great Britain, it would cause the grave problems of unemployment inevitable when remodelling the structure of industry. We need not be unduly timid about this because it will take a long time to surmount the technical and economic obstacles. It does, however, stimulate the spirit of curiosity and the will to look ahead which is often lacking in our old-established industries.

Factory Lighting in Wartime

In the Engineering Supplement to the *Siemens Magazine* of February 1941, there is an instructive article by Mr. C. J. Misselbrook on "Factory Lighting in War Time". The fifth report of the Departmental Committee on Lighting in Factories issued in June 1940 has given a number of important recommendations on this subject and indicates a minimum standard which, although it would have been regarded a few years ago as unnecessarily lavish, is now in accordance with all good modern lighting practice. The recommendations of the report may be divided into two sections, adequacy and suitability, each of which presents its own problems. War conditions have resulted in the introduction of unskilled or semi-skilled workers into the industrial world and the work of training them is greatly facilitated if they are not expected to strain their eyes on unfamiliar tasks with inefficient lighting. In addition, the calling up of young men and their replacement by older workers increases the need for good lighting, for as a rule the eyes of older people are not so efficient as those of the younger generation, and consequently need more light for the equivalent 'seeing conditions'.

As regards adequacy, the report recommends a minimum illumination of six foot candles without prejudice to any additional illumination required by the nature of the work. This is a large increase on the one foot candle which was considered satisfactory when the last report was published about three years ago, but is easily obtainable with modern high-efficiency light sources. The question of providing illumination raises also the question of the amount of heat produced, which is sometimes excessive and gives rise to uncomfortable working conditions. The lighting specialist can often reduce the amount of heat by using an alternative type of lamp. For example, the 'Sieray' fluorescent tube is a good alternative to the 200-watt gas-filled lamp giving approximately the same amount of light but operating at a much lower temperature. There are many instances where the type and standard of work require a higher intensity of illumination than can normally be provided by general lighting. If this is provided by local lighting, all such points should be fitted with opaque shades, as an imperfectly screened lamp is a very frequent source of glare, leading to eye-strain and sometimes to accidents. With regard to wiring, the question arises when raising the standard of illumination, whether it is more economical to employ electric discharge lamps with their higher initial cost or to rewire the building. Sieray lamps have often proved of great value in such cases, as they can be readily interchanged with tungsten filament lamps with no alteration in the existing wiring.

Royal Geographical Society Awards

The King has approved the award of the Royal Medals of the Royal Geographical Society as follows: *Founder's Medal:* Captain P. A. Clayton, for his surveys in the Libyan Desert and his application of this experience to desert warfare during recent operations; *Patron's Medal:* Dr. Isaiah Bowman, president of Johns Hopkins University, Baltimore, for his travels in South America and for his great services to the science of geography while director of the American Geographical Society of New York. The Council of the Society has made the following awards: *Murchison Grant:* Mr. C. T. Madigan, for his explorations and research in Central Australia; *Back Grant:* Mr. Alfred Stephenson, for his surveys in south-east Greenland and in Graham Land; *Cuthbert Peek Grant:* Mr. Marcel Aurousseau, for his valuable services as secretary of the Permanent Committee on Geographical Names; *Gill Memorial:* Captain F. Spencer Chapman, for his exploration of high peaks in Sikkim and Tibet.

Announcements

Prof. W. W. C. Topley, F.R.S., professor of bacteriology and immunology in the University of London, has been appointed secretary of the Agricultural Research Council in succession to Sir Edwin Butler, F.R.S., who has retired on account of ill-health.

On April 8 an earthquake shock was felt in western Japan. Surface faulting took place, which damaged a railway track, causing goods trains to be derailed. No casualties have been reported. On April 9 a strong earthquake was felt at Terni in central Italy. This was followed by a strong aftershock. Neither shock caused damage.

LETTERS TO THE EDITORS

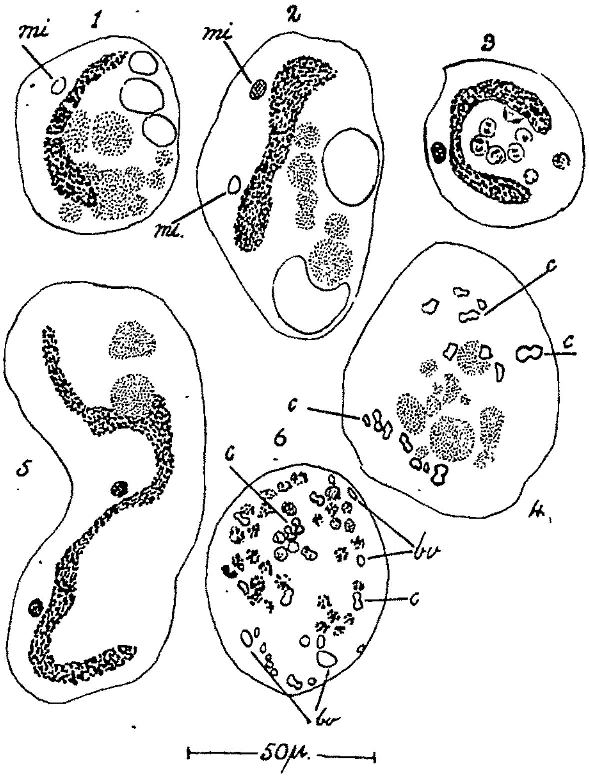
The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Virus Inclusions, Blastogenic Agents and Ciliates

THERE was reported in these columns[1] the production of abnormal Paramecia by 3 : 4-benzpyrene, and the information that these abnormal cells, by reproduction, gave rise, in the absence of the agent and indefinitely, to abnormal races showing widely varying polymorphism, like the cells of tumours.

Since then, similar races of abnormal Paramecia and other Ciliates have been produced by suitable exposure to the following blastogenic agents: cyclic hydrocarbons, gamma and ultra-violet radiations, heat, cold and hypertonic dextrose.



NOS. 1, 2 AND 5 ARE SPECIMENS FROM THE INFECTED CULTURE STAINED BY FEULGEN'S METHOD; THE NUMBER OF PARTICLES PER UNIT AREA IS APPROXIMATELY CORRECT; IN NO. 1 THE MICRO-NUCLEUS (*mi*) IS UNSTAINED; IN NO. 2, WHICH IS A DOUBLE, ONE IS UNSTAINED AND THE OTHER FAINTLY STAINED; NO. 5 IS A DOUBLE-MONSTER; NO. 3 IS A NORMAL WELL-FED ORGANISM STAINED FEULGEN; NO. 4 IS AN INFECTED CELL STAINED GRAM AFTER FORMALIN VAPOUR FIXATION, IT SHOWS INCLUSION BODIES AND DUMBELL CRYSTALS (*c*); NO. 6 IS A NORMAL STAINED INTRA VITAM WITH CRESYL BLUE, IT SHOWS FOOD VACUOLES, CRYSTALS AND BLUE VACUOLES (*bv*).

The possibility that a virus might be playing a part has been kept in mind; nothing suspicious was noted until a few weeks ago. In a culture of Aspidisca sp. subjected to 40° C. for one minute, abnormals were sought for; they occur for 24–48 hours after such an exposure. None was found, as is often the case, since they are always of rare occurrence. In the culture, six days later, I was astonished to see many abnormals, far more numerous than ever seen before. Some were picked out and stained by Feulgen's method; they showed in the cytoplasm, collections of minute stained particles, similar to virus inclusions (see accompanying figure).

These inclusions are easily distinguished from food vacuoles containing bacterial debris shown in Nos. 3 and 6. It may be mentioned that organisms fed on Gram positive Staphylococci do not show Gram positive cocci in the food vacuoles: they become Gram negative. The inclusions appear to lie free in the cytoplasm and not within a vacuole. They have never before been found in Aspidisca, either in normals or in abnormals produced by blastogenic agents.

The infected culture was sub-cultured to many well slides, under conditions known to favour abundant growth. Instead of reproducing, they ceased to divide and gradually died out, all being dead on the twenty-second day. Many attempts to infect normals and cells subjected to blastogenic agents were unsuccessful.

Two other facts are worth recording. Accompanying the presence of abnormals in the infected culture, were seen all the signs of increased cytoplasmic viscosity which has invariably been observed preceding the production of abnormals by blastogenic agents. There is, therefore, a similarity in the reaction of the cells to virus and to blastogenic agent. I also noted that in many cases, the micro-nuclei failed to be stained by Feulgen, see Nos. 1 and 2; perhaps the supply of nucleic acid to the micro-nuclei is interfered with, being all grabbed by the virus; in these specimens one also sees unstained bands, see No. 1, in the macro-nucleus as though it, too, was deprived of nucleic acid.

I would be very grateful for any information on virus or virus-like inclusions in the Protozoa.

Palæochemistry of the Ocean

A quantitative account of oceanic palæochemistry depends largely on the theory accepted for the origin of the ocean, especially for its halogen content. Yet with any tenable view, useful limits for biological consideration can be established for such quantities as the total salinity at the beginning of the Cambrian period. The K/Na ratio of the original ocean can also be stated with some confidence, when we consider that the mean composition of igneous rock has not appreciably changed over the oceanic age.

The original K/Na ratio of the ocean. The speculations of Macallum[1] on the origins of the cellular potassium, and the vogue they have obtained, makes this question of some interest to the biologist. According to Macallum, potassium was more concentrated than sodium in the primitive ocean (the K/Na ratio being about 2·0) and the cell to-day with more potassium than sodium tends to repeat in an altered environment a primitive adaptation. As evidence for the higher potassium concentration he cites analyses of Reindeer Lake and Churchill River[2] situated in the zone of Archæan rock in Canada. Against this there is the Ottawa River[3], in a region of similar rock with a K/Na ratio less than unity (0·64). The Hayes and Nelson Rivers[4], draining wide areas of Archæan as well as later sedimentary strata, have a K/Na ratio of 0·32 and 0·16, which are *less* than the total river average of 0·37[5]; and the Mahanuddy, which in India drains a wide area of Archæan rock, has a K/Na ratio of only 0·28[6].

Occasionally, high K/Na ratios may be found in rivers and lakes not associated with crystalline or Archæan rock, for example, in the Würmsee and Königsee[7] (Macallum cites such as evidence for his view when it is clearly against it); and the potash lakes of Nebraska[8] occur, too, in regions where there is no outcropping of igneous or Archæan formations.

At the same time there is no apparent reason why potassium should be higher than sodium in the early seas, since the K/Na ratio in igneous rock is 0·92, and whether we consider the action of neutral or very weakly acidic rain, or of hydrochloric acid, potassium is not more readily dissolved from the rock than sodium. It is dissolved less readily. This may be proved from Merrill's studies[9] of rock weathering, from the mean analyses of rivers draining igneous rock, and from Taylor's laboratory experiments[10] with hydrochloric acid.

Occasional high K/Na values are simply explained by a *local* preponderance in the rock of potassium compounds such as orthoclase, leucite, or biotite.

Oceanic salinity at the beginning of the Cambrian period. Whether we suppose the oceanic chloride to have been present almost entirely in the original atmosphere of a cooling earth, or to have originated as meteoritic chloride of iron, or again to have condensed along with the water of the ocean from volcanic emissions, the total ionic content will not change greatly, if at all, from its value at the outset. Only on one theory of the origin of the ocean, in which the chloride, but not the water, has been entirely supplied from volcanoes, does it alter from something like lake water to its present composition.

With such a theory and a consideration of the relevant data it may be shown that the salinity at the beginning of the Cambrian age was about 1·6–2·0 per cent. In this estimate account is taken of the changing relation of igneous to sedimentary surface, of the different proportions of sodium to sediment in water draining igneous and sedimentary rock; and it is also assumed that the total depth of the pre-Cambian strata is 40 per cent of the whole sedimentary depth, which would appear to represent approximately the current view. Even if we reduced the figure to 25 per cent the salinity at the beginning of the Cambrian period would still be 1·2–1·6 per cent. Equating, therefore, the salinity of mammalian blood (about 0·9 per cent) with that of the Cambrian ocean, in which Protovertebrates may have first appeared, is a speculation not supported by the geochemical data. This, however, does not militate against the view that the ratios of the inorganic ion concentrations in mammalian plasma may have broadly an oceanic significance (Bunge[11]; Quinton[12]).

A more detailed consideration of such questions will be submitted to the Royal Irish Academy.

Control of the Kromnek (Spotted Wilt) Disease of Tomatoes

In many seasons the kromnek disease causes heavy losses in both tobacco and tomato in the Cape Province and Transvaal. Its virus origin was first diagnosed[1] in the Kat River area of the eastern Cape Province, and it has since been identified with the spotted wilt disease now well known in many parts of the world. In the Kat River area it is transmitted mainly, if not entirely, by the feeding of a thrips (*Frankliniella schultzei* Trybom) which has a wide host range among both wild and cultivated plants.[2] The virus likewise attacks a very great variety of plants[3] and the control of the disease is therefore a very difficult problem which has not so far been solved for South Africa.

Tartar emetic is used effectively against the citrus thrips in America, and preliminary trials with it at this laboratory have given very promising results with regard to the control of kromnek in tomatoes. The formula used was the same as that advised for citrus thrips, namely, 1 lb. tartar emetic plus 2 lb. sugar to 100 gallons of water. Spraying was started in the outdoor seed-bed in October when the seedlings were still in the cotyledonary stage and were already being attacked by the disease vector; it was repeated frequently during the subsequent nine weeks. Control beds a few yards away were left unsprayed;

at a height of four inches they developed the symptoms of kromnek and became 100 per cent infected, growth immediately coming to a standstill. An outstanding contrast was offered by the sprayed beds, which showed vigorous healthy growth, not more than 5 per cent of the plants becoming diseased. Those left in the beds after thinning yielded a bountiful crop.

Spraying of transplanted tomatoes gave promising results, in view of the very small scale of the tests and of the consequent continuous invasion of insects from the unsprayed rows to the trial rows adjoining.

Inactivation of the Causative Agent of Fowl-Leukosis by X-Rays

THE following is a report on the inactivation of the causative agent of fowl leucosis (hæmacytoblastosis, Strain *T* Engelbreth-Holm) by means of X-rays.

The method used was as follows: blood was withdrawn from the animal at the height of the infection, with the addition of sodium citrate. A drop of this blood was placed on a concave slide, covered with a mica coverslip 0·03 mm. thick and made air-tight with paraffin. Blood drops mounted in this way were irradiated. After irradiation every drop was diluted with 2 c.c. of Ringer's solution, and 1 c.c. of the diluted blood was inoculated intravenously into a fowl. Altogether six series of experiments were carried out on thirty-four fowls. Control experiments were made for each series with non-irradiated blood.

Irradiation was carried out by means of a demountable X-ray tube with copper anode operated on a vacuum pump at a tension of 35 kv. and a current of 30 ma. The intensity of the X-rays was about 105,000 r./min. at the distance of the irradiated subject. According to absorption analysis the overwhelming part of the radiation used consisted in characteristic *K*-rays of the anode material (copper). The half-value layer in aluminium was 0·053 mm. The results are given in the accompanying table.

Leucotic virus is destroyed with certainty by a dose of 4,000,000 r.; 2,000,000 r. has no effect. When 3,000,000 r. is used results vary. We obtained three negative results against two takes; both the latter showed an anæmic form of hæmacytoblastosis.

X-ray dose in million r.	No. of chicks injected	Successful injections	Unsuccessful injections
½	2	2	0
1	2	2	0
2*	4	4	0
3	5	2*	3
4	11	0	11
5	6	0	6
6	4	0	4

* Anæmic forms.

The doses used by us for inactivating the agent of fowl leukosis lie in the same range as those used for inactivating the few viruses of which the resistance to irradiation has been determined. The inactivating dose for fowl plague virus is 3,000,000 r. (Levin and Lominski[1]), for infectious papilloma of the rabbit 3,000,000 r. (Lacassagne and Nyke[2]), for vaccinia somewhat more than 3,900,000 r. (Gowen and Lucas[3]). The doses used by us for inactivation are many times larger than those employed hitherto in attempts to influence the leucotic agent, and this is undoubtedly the reason for the negative results obtained by Engelbreth-Holm and Rothe-Meyer[4], by Forfota[5] and by Jarmai[6].

This work has been aided by a grant from the Lady Tata Memorial Trust.

Diffuse X-Ray Reflexions

FOLLOWING the observation by Sir William Bragg that diffuse scattering takes the form which it should have if it were due to diffraction by small groups of atoms within a crystal (as originally suggested by Preston), Prof. G. E. M. Jauncey[1] has obtained a formula giving the resulting positions of the diffuse spots for small values of $(i - i_B)$, i being the glancing angle of incidence on the set of crystal planes for which i_B is the Bragg angle. He expresses astonishment that this formula is identical with those deduced by Zachariasen and by Raman and Nath, each on very different assumptions. Mr. G. D. Preston[2] has pointed out that this formula is an approximation to the formula given by Faxén in 1923, and stated that the physical interpretation of Faxén's formula is that the surfaces of constant intensity surrounding the Bragg points are spheres. This, however, is again *only true when* $(i - i_B)$ *is small.*

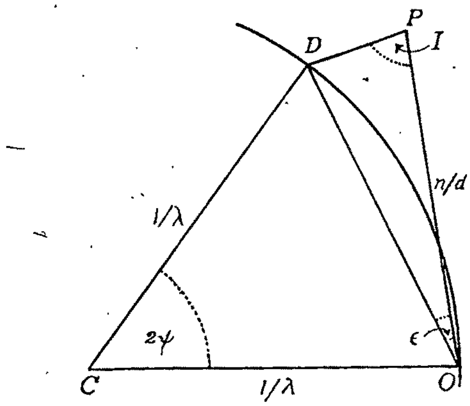
The reason why all these different assumptions (for example, existence of small groups, waves of the Raman type or elastic heat waves) give the same formula for small values of $(i - i_B)$ is that in the derivation of each formula it is implicitly or explicitly assumed that the spreading of the intensity of reflecting power around each reciprocal lattice point is independent of direction. Consequently, the formulæ are simply a geometrical way of expressing the fact that *near* the reciprocal lattice points the distribution may be taken as spherical.

Raman and Nath's more general formula

$$d \sin \psi \sin (I - \varepsilon) = n\lambda \sin I$$

is also only a *purely geometrical relationship* connecting the centre C of a sphere with two points O and D on its surface and one point P not on the sphere (P not necessarily in the plane of C,O,D). Faxén's formula applies to the special case where C,D,P are collinear.

Without detailed experimental information, the physical interpretation to be applied to such a general formula is largely a matter of choice. Part of the information required, of course, is precisely that referred to by Preston, namely, the shape of the surfaces of isodiffusion (expression due to J. Laval), particularly when $(i - i_B)$ is *not* small. Such experimental observations, made in this Laboratory, show quite definitely that in general these surfaces are *not spherical.* For diamond, indeed, the reflecting region around the (111) reciprocal lattice point has been shown to possess six horns pointing along the six [100] directions[3]. Unfortunately, however, even this information is not enough. M. v. Laue[4] has shown, for example, that for a finite crystal of octahedral shape, the reflecting region around a reciprocal lattice point has eight horns, but either wave theory will lead to similarly shaped regions provided that along certain crystal directions the atoms tend to remain always in phase.



The experimental information most to be desired at present is that relating the surfaces of isodiffusion for various reciprocal lattice points (to be experimentally determined) with other physical properties of the crystal, such as temperature, perfection, elasticity coefficients, and so on. Work along these lines is now in progress, but it is clear that the subject opens up a very wide and fascinating field of research.

A Property of Conjugated Systems

In a compound of the type $X.(CH = CH)_nY$, the conjugated system is an electronic conductor between the covalent groups X and Y, and there must therefore be a correspondence between such chemical properties of the compound as leave the conjugated system intact and those of the covalent compound $X.Y$. This generalization has been recognized in the particular case of carbonyl compounds, but its wide value as a very general means of insight into the reactivity, as well as the mechanism of reactivity, of the compound $X.Y$, seems to have been overlooked.

The most readily available conjugated systems are those of *ortho-* and *para-*benzene derivatives, and the generalization at once disposes of the old supposition of a fundamental contrast between aromatic and open-chain chemistry. Nevertheless, the possibility of nitrating paraffins which, in this light, follows from that of nitrating alkyl benzenes, has only latterly been realized and put into technical operation. This example also serves to illustrate the efficacy of the aromatic resonance in promoting reactivity, a factor which must be allowed for in applying the principle. Although it is for this reason safer to deduce the behaviour of XY from that of the conjugated compound than to do the reverse, nevertheless it is clear that the possibility of chlorinating or nitrating XH to $X\,Cl$ or $X\,NO_2$ can provide a criterion of the ortho-para directive effect in aromatic substitution.

Again, the mechanism of *para-*nitrosation of dimethyl aniline must be reproduced in that of dimethylamine, and it is obviously not permissible to regard the latter as involving the salt of the base if, as is accepted, the former involves the free base. The widely accepted view, based on the results of kinetic measurements[1], that nitrosation and diazotization involve the salts of bases, is therefore untenable; the function of the protons, which such measurements show to participate in the reaction, must therefore be to activate the nitrous acid. It is, however, hoped to show in a fuller discussion of this reaction that other reasons independently point to the same conclusion.

The principle also constitutes a bridge between organic and inorganic chemistry, of the more value because in the latter the study of reactivity and mechanism is little advanced. Thus the mode of oxidation of hydrogen peroxide, hydroxylamine, and hydrazine respectively must correspond to those of hydroquinone, *p*-aminophenol and *p*-phenylene diamine. The *o-p* nitration of chlorobenzene must be reflected in that of hydrogen chloride, which doubtless represents the first stage in the familiar formation of nitrosyl chloride and chlorine. The nitration of aniline (as acetanilide) shows that, as indeed Franchimont[2] surmised, nitramide is an intermediate in the preparation of nitrous oxide from ammonium nitrate; similarly, the formation of nitrogen from ammonium nitrite is, as has also been shown kinetically[1], a case of diazotization.

RESEARCH ITEMS

Stimulation of Algal Growth by Ultra-Violet Radiation

The research on this topic, which has been progressing for some time at the Smithsonian Institution, has produced results of considerable interest, and the recent contribution by F. M. Chase (*Smithsonian Misc. Coll.*, 99, No. 17) promises to be of importance in some aspects of the physiology of development. Cells of the alga *Stichococcus bacillaris* exposed repeatedly to the stimulative action of four wave-lengths of the ultra-violet grow much more rapidly than do the controls. Four successive irradiations at 2352 A., for example, stimulate the cells to a growth-rate (as measured by cell number) of 4·7 times the controls. This stimulation is of the same order for the first irradiation by all four wave-lengths employed (2352 A., 2483 A., 2652 A., 2967 A.), but in general the additional stimulation on further irradiation is the less marked the longer the wave-length. The interesting point about this stimulation is that the enhanced growth-rate leads not only to a decrease in cell length, as might be anticipated, but also to a somewhat increased cell breadth. The volume relations are more complex. On first stimulation the volume of a cell is greater than controls for all four wave-lengths, and on second stimulation for the two longer wave-lengths. With the very rapid multiplication which occurs at the shorter wave-length the volume soon falls below that of the controls. The changes which thus occur in the appearance of the cells, and these are quite striking judging from the published photographs, are permanent. The irradiated cells are also changed somewhat in internal organization, for they are now less sensitive to lethal exposures to ultra-violet than are untreated controls.

Coco-nut Disease in Jamaica

The rapid destruction of coco-nuts in the western end of Jamaica is now considered to be due to bronze leaf wilt (F. M. Bain, *Bull.* 22, Dept. Sci. and Agr., Jamaica, 1940). As well as producing characteristic leaf symptoms, the disease also results in a dropping of the nuts. Unsatisfactory conditions of water supply within the plant tissues are held responsible for the pathological symptoms observed. Affected plants may show a progressive dying back during several seasons with eventual mortality, or, as may also happen, the plant may die suddenly. Both types of the disease are related to conditions of moisture deficiency, and are referable to the details of root distribution, root mortality, soil type, and soil moisture relationships—on all of which points the author has advanced new and interesting data. It is possible, for example, to make a working classification of the soil types and characteristics on which wilt disease may be expected to occur. From such considerations the author reaches the conclusion that the application of curative measures in the field is impracticable, except in areas where affections of the progressive type are still in an early stage. Preventive measures also present serious difficulties, including the economic aspect, and in some instances direct attention to the need for securing alternative paying crops. Drainage, irrigation, trenching, mulching, manuring and spacing may each and all, in suitable circumstances, be expected to afford some alleviation of this type of wilt.

Development of the Seed in Angiosperms

R. A. Brink and D. C. Cooper (*Bot. Gaz.*, **102**, 1–25 ; 1940) have studied the histology of double fertilization and its effect on the developing embryo of alfalfa. They show that 34·4 per cent of fertile ovules abort within 144 hours after self-pollination, whereas only 7·1 per cent abort after cross-pollination. This abortion is due to the inability of the endosperm to keep pace with the growth of the surrounding tissues. The embryonic cells increase in an arithmetical progression, whereas the nuclei of the endosperm are without cell walls and increase geometrically during this period. The rate of growth of endosperm after cross-fertilization is significantly greater than after self-fertilization. Statistical data on the development of the embryo and endosperm are provided and the role of double fertilization in seed formation is discussed. The physiological advantages of double fertilization in angiosperms and the evolutionary connexion between incompatibility, heterosis, double fertilization and cross-pollination are pointed out.

Œnothera cantabrigiana

B. M. Davies (*Genetics*, **25**, 433–437 ; 1940) found plants in the Cambridge Botanic Garden which were similar to *Œnothera biennis* but which had red anthocyanin pigmentation on various parts. Cytogenetical analysis showed that these plants gave *laeta* and *velutina* forms in the same way as *biennis*, but in place of *rubens* being given by the pollen and *albicans* by the pollen as in *Œ. biennis*, these are given by the egg and pollen respectively in *Œ. cantabrigiana* ; the pollen and egg lethals have crossed over.

Heterosis

A further contribution to the problem of heterosis has been made by work on the tomato by E. S. J. Hatcher (*Ann. Bot.*, N.S., **4**, 735–765 ; 1941). There are high correlations between number of seeds in the fruit, weight of seed and fruit weight. Size heterosis appears at the stage of differentiation of the cotyledon primordia in the embryo. Embryo size at maturity is largely influenced by the maternal tissue, therefore reciprocal hybrids may have different embryo sizes. After germination, the cotyledons but not the plumule-meristem show heterosis in the hybrids. It is shown that embryo size is in no way determinate—indeed heterosis only becomes obvious after the flowering stage, while seeds of the same genotype which differed considerably in weight gave rise to plants of uniform size. The author therefore supports the theory of Jones involving complementary action of dominant factors.

Metamorphism in New Zealand

An early Palæozoic geosyncline appears to have occupied the greater part of Otago in the south of New Zealand, and in it was deposited a thick series of quartzo-felspathic sediments, interstratified with other types and with contemporaneous basic volcanic rocks. Probably in Permian or early Triassic time these rocks were folded and subjected to regional metamorphism. The details of this metamorphism on the rocks of an area of about a thousand square miles in the Lake Wakatipu region of Western Otago have been thoroughly investigated by C. O. Hutton, whose results have recently appeared (*Geol. Mem. N.Z. Dept. Sci. Ind. Res.*, No. 5, pp. 84 + 17 plates; 1940). The region furnishes an excellent example of progressive metamorphism within the chlorite zone, which has been subdivided into four subzones based on textural criteria and the degree of reconstitution suffered by the rocks of greywacke composition, which are here dominant. Subzone 1 is represented by slightly altered greywackes with lack of foliation. In 2 foliation appears, the rocks are semi-schists, and clastic grains are much reduced in size and number. As the isograd between 2 and 3 is reached, reconstitution becomes more complete and the clastic grains disappear. The rocks of 3 are perfectly schistose and include quartzo-felspathic schists and albite-epidote-chlorite-schists. The major part of the area falls into subzone 4, the rocks of which are characterized by a marked increase of grain size and of coarseness of foliation. In the associated green schists greenish biotite becomes abundant, but the red-brown variety of the biotite zone is not developed. The types derived from greywackes have quartz and albite as the dominant minerals, generally accompanied by epidote with chlorite or actinolite. The memoir is well illustrated and the petrographic descriptions are supported by many new chemical analyses.

The Shallowater Meteorite

THE meteorite of this name was found near Shallowater, Lubbock County, Texas, in 1936, the weight of the stone being 4,750 gm. It is an extremely coarsely crystalline aubrite composed of 81 per cent of enstatite, 5 of fosterite, 2 of oligoclase, 9 of nickel-iron, 1·5 of troilite and 1·5 of miscellaneous constituents (W. F. Foshag, *Amer. Min.*, 779–786; December 1940). A remarkable feature of the magnesium silicate minerals is their practical freedom from iron. The enstatite occurs as lath-like crystals up to 4·5 cm. long arranged in a coarsely reticulating texture. This fact, together with the lack of any evidence of the derivation of the enstatite from a monoclinic form, and the occurrence of olivine as grains in the enstatite, suggests to the author that the stone may be a product of direct crystallization from a magma, and not an accumulation of crystals from a magma of different composition. A more serious difficulty in interpreting the mode of origin of the stone is the association of nickel-iron and troilite (FeS) with iron-free silicates that normally contain iron. It is hard to believe that there was such an extraordinarily fine balance of the oxygen supply during crystallization that there was just sufficient to satisfy the magnesium and none available for any of the iron, particularly as the peculiarity is shared by other aubrites. On the other hand, there are indications that the nickel-iron and troilite may have been later introductions. Evidently this problem of the relation of nickel-iron to silicates in stony meteorites requires serious attention.

Tin Research

THE art of coating metals with tin by dipping them into the molten metal is one of considerable antiquity, and this method of tinning, known as 'hot-tinning', is still the most widely used. In recent years there have been considerable advances in the method of electro-deposition, but it may be said that the two processes fall into two distinct categories. By the hot-tinning process bright lustrous coatings up to 0·001 in. in thickness may be obtained and they do not tarnish readily. Electro-deposited coatings may be of any desired thickness but are matt when they emerge from the plating bath and give only a satin finish when polished. The hot-tinning process depends on experience and personal skill, and laboratory control is not necessary. As a result, the process has been neglected by research workers. Literature and technical data are very scanty and it is therefore very timely that a book should have been issued by the Tin Research Institute, Greenford (Publication No. 102: "Hot-Tinning" by C. E. Horner. Pp. 28) dealing with the processes used in hot-tinning fabricated articles of various kinds but not including the manufacture of tinplate or the continuous tinning of strip or wire. After describing the preliminary processes of degreasing and pickling, the book discusses the various types of tinning baths, their operating temperatures and their maintenance in continuous operation. Much of the value of the publication lies in the explanations given of the advantages associated with the different processes, of the causes of blemishes, of the conditions which influence the brightness of the coating and other practical points. Its contents are based on the experience and information accumulated by the Institute over a number of years and on the experimental work carried on in its laboratories. Although only a brief review of the subject, the directions given on the hot-tinning of articles of steel, iron, copper and copper alloys will be found of the utmost practical value.

Figures of the Earth and Moon

A PAPER on this subject by Harold Jeffreys (*Mon. Not. Roy. Astro. Soc.*, **101**, 1) is supplementary to a previous paper which appeared about four years ago (*Mon. Not.*, **97**). Immediately after the publication of the latter paper, E. W. Brown published a correction to the solar contributions to the motions of the moon's node and perigee, and this necessitated certain corrections to the determinations by Jeffreys, which were given in a revised solution (NATURE, **139**, 471; 1937). Jeffreys has also made a new discussion of the observations of gravity over the surface of the earth and has attempted to determine the harmonics of low order other than the main elliptic term (*Mon. Not. Geophys. Suppl.*, **5**, 1). While there is good evidence that some harmonics other than the main ellipticity term are present, "the data are not adequate to separate them, mostly on account of the lack of data for the South Pacific and high southern latitudes". The new estimate of the main ellipticity term in gravity contains an uncertainty because it rests on a hypothesis of randomness which will require further check. Jeffreys has made a complete new solution, in the first paper referred to above, for the constants involved, and the results are considered satisfactory. A difficulty arises in the disagreement between the moon's dynamical and visual parallaxes. Lambert has shown (*Astrophys. J.*, **38**, 181–5; 1928) that the dynamical parallax exceeds the visual by 0·16″ if the ellipticity is taken as 1/297, and agreement is reached if it is taken as 1/293·5, but it is suggested that the discrepancy may be due to an abnormal deflexion of the vertical at Cape Town.

CRYSTALS AND PHOTONS

In his presidential address to the Indian Academy of Science, Sir C. V. Raman surveyed recent progress in the investigation of those phenomena which are observed when radiation is scattered in a crystal (*Current Science*, January 1941. Supplement). The subject is a natural extension of the well-known Raman effect usually observed in liquids, which has proved such a fruitful source of knowledge concerning molecular vibrations.

The analogous effects observed in crystals are, according to Raman and his collaborators, the result of interaction between the incident radiation and the material particles of the crystal. As a result of the absorption of energy from the incident beam, the regular geometrical array of atoms or molecules in the crystal is set into vibration. The lattice waves in the crystal can then be regarded as stratifications of density which may reflect the energy preferentially in certain directions. Owing to the interchange of energy between radiation and matter, the reflected ray suffers a change of wave-length. Thus when a diamond is illuminated by monochromatic radiation, the scattered ray contains two components with wave numbers differing by $\pm$ 1332 cm.$^{-1}$ from the wave number of the incident ray. This change of frequency appears on the quantum theory as the result of an exchange of energy between a photon and the crystal, a diminution occurring if the photon is the donor and the crystal the acceptor, an increase if the reverse is the case.

In the experiment just described, the radiation is scattered in all directions from the crystal; but Sir C. V. Raman also envisages circumstances in which the incident radiation is regularly reflected in certain directions. He states that infra-red radiation, within a certain range characteristic of the material, is strongly reflected backwards by the crystal because the optical vibrations of the lattice are powerfully excited by the incident waves. Recently, the observation of similar phenomena has been extended to the range of X-ray frequencies. According to Raman, the optical vibrations of the lattice, excited by the incident X-rays, create dynamic stratifications of the electron density, and these give regular reflexion of X-rays with a change of frequency in much the same way that the static planes of atoms give the classical Bragg reflexions without change of frequency.

These ideas are obviously of great interest, especially with regard to the reflexion of X-rays. This part of the subject has received considerable attention in both Europe and the United States. Reference to the correspondence columns of NATURE in the last year or two shows that the X-ray phenomena which Raman describes have been ascribed by other investigators to reflexion from the thermal waves in the lattice. The difference in point of view seems to be that Raman considers the lattice waves to be a result of excitation by the incident energy, and he also postulates a frequency change in the scattered energy. His case would be greatly strengthened by direct observation of this frequency change, which is, unfortunately, too small to be detected at present. The other approach to the problem regards the lattice waves as being already present in the crystal as a result of the thermal vibrations of the atoms, and the observed effects do, in fact, appear to be explicable on these lines. Whether a quantum mechanism is necessary for an accurate description of the phenomenon would seem to be a matter for still further investigation (see also p. 467 of this issue).

DAMS AND THE PROBLEM OF MIGRATORY FISHES

The special symposium issue, with the above title, of the *Stanford Ichthyological Bulletin*, published through the co-operation of the Fish Commission of the State of Oregon and the Natural History Museum of Stanford University, comprises a number of papers read by leading fishery authorities in the United States on the problem presented by the construction of dams for generating electric power and for irrigation of agricultural land in certain States on the Pacific seaboard of North America.

The dams in question—already constructed or to be constructed—are in the basins of the Columbia and Sacramento Rivers. The fish mainly affected are the anadromous Pacific salmon (Oncorrhyncus)—chinook, blue back and cohoe—and the steel-head trout; fish which are of great importance in connexion with the world-famed commercial fisheries of the North American Pacific coast. Consideration has had to be given to the question of the effect these dams will have not only on the ascent of the breeding fish to their customary spawning grounds (and on the spawning grounds themselves) but also on the descent of the fry (and spent adults).

Fundamentally, a proposition of this nature resolves itself into the formulation of two questions, namely, (*a*) are such industrial developments on a river compatible with the continued maintenance of the fisheries in that river, and (*b*) if the answer is in the negative, are the fisheries to be regarded as of secondary importance and therefore inevitably to be sacrificed—the issue being the relative merits of each *quâ* progress ? A subsidiary question will be the cost of the necessary measures involved under (*a*) to safeguard the fishery interests. If the cost is high it may be urged that the proposition really comes under heading (*b*).

At the outset neither of these questions seems to have even suggested itself to the industrial interests bent on exploiting these rivers as power generators. Nor does it appear that the central authorities vested with the power of supervisory administration (and whose consent had to be obtained in the first instance) were any more alive to the situation and to its implications. It devolved upon the fishery interests, through the American Bureau of Fisheries, to direct attention to the probable effect on the fisheries and to the very considerable monetary value to the community at large of those fisheries. Incidentally, these schemes were apparently initiated in connexion with the relief of unemployment

In the Columbia River system four of the dams are either already constructed or in process of being constructed; and there are nineteen others contemplated. In the Sacramento River two are constructed, or nearing completion, and the erection of fourteen others is under contemplation. The heights of two of these are mentioned, namely, at Grand Coulee on the Columbia River, 350 ft., and at Shasta on the Upper Sacramento River, 560 ft. The United States fishery experts are therefore obviously confronted with a problem of exceptional magnitude. How they are proposing to tackle it is set out in the symposium.

As regards the Grand Coulee Dam alone, which is going to eliminate some 600 miles of main river and 530 miles of tributaries as breeding ground, it is estimated that the runs of fish involved represent an annual value of an investment amounting to a capital outlay of 11,000,000 dollars yielding 4 per cent (or approximately £88,000 per annum), this area representing apparently about one third of the total catchment area of the Columbia River.

Grand Coulee Dam is 350 ft. in height; and the fishery experts have reached the conclusion that any measures devised to facilitate the ascent of fish to the waters above would cost at least 2,000,000 dollars "with a very good chance that they would not work". These measures, moreover, would be irrespective of what would have to be done—if practicable—to safeguard the downward migrating fry and spent fish (in this case the spent fish would be only among the steel-head trout, as all the so-called salmon of the Pacific die after spawning once).

The only alternative presenting itself was to divert the fish that would normally spawn above the site of the dam to tributaries entering the river below, where they would be held until ready to spawn, the intention being to let the fish spawn in the natural way in the spawning grounds previously investigated and regarded as probably suitable and adequate. The means adopted to secure this diversion, the difficulties and expense involved, are described.

The diversion had to be effected by actually transporting the fish from a dam (of surmountable dimensions) lower down. The fish were deposited at the mouth of the stream draining the tributary system selected (which was racked to prevent them dropping down stream), but unfortunately the fish failed to proceed upstream to the appointed place. Accordingly they had to be transported to where it had been intended they should go, and where they were retained until ripe eventually for stripping, the ova being fertilized and hatched artificially and the fry distributed over the selected rearing grounds.

It is, as yet, by no means certain that success will attend these efforts. Whether the available rearing ground will prove adequate for the quantity of fry released, and if so whether the returning adults resulting therefrom will be disposed to find the same streams where they were reared as fry, or whether they also will have to be diverted by actual transportation as were their progenitors, remains to be seen.

In the Sacramento River system the problem seems to be an even harder one. Here the embankment of the dam being constructed will be 560 ft. in height. It will impound the waters not only of the upper third of the Sacramento River itself but of the whole of the McCloud and Pit Rivers, permanently cutting off some 112 miles of previously available spawning and rearing ground.

In view of its cost and its problematical practical value when constructed—having regard to the height to be surmounted and to the seasonal fluctuations of the surface water-level (amounting to upwards of 200 ft.)—the idea of a fish pass had to be abandoned. There remain the alternatives of either diverting the fish to other still available spawning grounds in tributaries entering the main river below the dam or, after collecting the spawners, hand stripping the fish and sowing the fry in waters where they would have a chance of developing and from which they could migrate downstream without danger to themselves. From previous counts that have been made of the runs of fish going up past the site of the Shasta Dam it is estimated that in the case of the second alternative a total of approximately 100 million ova would have to be handled, "a number greater than that which is now produced by all the federal salmon hatcheries".

Schemes of this magnitude are not (and are never likely to be) encountered in Great Britain. There are, however, a number of impounding dams in England and Wales and (as yet not so many) in Scotland for the storage of water required by townships for domestic and industrial purposes. These are mainly in the headwaters of rivers, and though considerably less in height and dimensions than those which are the subject of discussion in the symposium under consideration, the problem they have presented has points in common.

The dams themselves are, of course, quite insurmountable by ascending fish and, because until recently the technique of dealing with the fluctuating surface-level of the reservoirs created by the dam had not been grasped, the notion of a fish pass to enable the fish to get up had been more or less dismissed. In any event the consequent extensive flooding of country above the dam so reduces the available area of spawning and rearing ground that the cost of a fish pass was deemed to be scarcely worth while. Moreover, the question of the descending fry and spent fish remained unsolved owing to the fluctuating top-water level of the reservoir and consequently to the uncertainty as to where, when and how egress could be found for them.

The difficulties presented as regards the ascent of the breeding fish and the subsequent descent of the fry and kelts have now to some extent been met by the idea of a fish pass with an adjustable feed from the reservoir, as has been adopted at Tongland (where the range of fluctuation in the top-water level does not exceed 41 ft.) and at the other impounding reservoirs on the same river system (the Kirkcudbright Dee) which are comprised in the Galloway Power Scheme.

At Tongland a large proportion of the fry pass through the turbines apparently without serious harm. The remainder, together with the spent fish, eventually find their way to the fish pass intake. The Tongland dam is 72 ft. in height and is the lowest situated of the series of dams, being immediately above the tidal water. It was, therefore, of vital importance to make it surmountable if the salmon of the Dee were not to be exterminated. That the measures taken to that end have been successful is apparently the case, and it can be assumed that the similar measures at the other dams above have been equally successful.

Though Tongland and its associated dams store water for power and not for distribution, the principle involved is the same as that applying to large imdounding dams generally. In each case there is the problem of assisting the fish (descending as well as ascending) over or round the dam, complicated by the fact that the top-water level of the reservoir varies according to meteorological and seasonal conditions.

An additional problem presented by, and peculiar to, the impounding of water for generating power, as distinct from supply, is the draw through the turbines. If there is adequate clearance between the blades, and the revolutions per minute do not exceed a certain—as yet not fully determined—maximum, small fish, such as smolts, can pass through, as they do at Tongland (and elsewhere) without hurt. It is probably better to let these small fish avail themselves of a quick exit from the reservoir by this, usually more readily found, route rather than compel them, by the interposition of closely interspaced gratings at the turbine intake, to seek it after probable delay through the fish pass intake. Screened, but by a grating with relatively wide interspaces, the turbine intake must be, however, to prevent the larger adults, spent and dropping downstream as kelts, from getting involved in the turbines, with certainly fatal results—to the fish.

It might be supposed that what has been possible on the Dee at Tongland would be equally possible on the Columbia and Sacramento Rivers. The magnitude of the proposition on the latter rivers, however, removes it to a somewhat different category. On no single river system in Britain has it been nor is it likely to be, necessary to contemplate an overflow at any dam amounting to as much as 650,000 cu. ft. (as at the Grand Coulee on the Columbia River), or an annual catch of salmon exceeding 1,500,000 lb. (as is the case in regard to one commercial fishery alone at the mouth of the Sacramento River).

It requires no exceptionally acute imaginative faculty to realize that the problem in these Pacific coast rivers is on a scale which introduces a somewhat different standard of outlook and demands a special mode of treatment.

The fight of the fishery interests to prevent the extermination of these important and valuable fisheries will be watched with sympathetic interest.

THE INTERNAL COMBUSTION ENGINE

THE full text of the series of three Cantor Lectures of the Royal Society of Arts delivered by Prof. S. J. Davies under the title "Recent Developments in Internal Combustion Engines", is now available (*J. Roy. Soc. Arts*, Feb. 1941).

In his opening remarks Prof. Davies quoted the prophecy made by Sir Frederick Bramwell at the jubilee meeting of the British Association in 1881 with respect to the steam engine: "I very much doubt whether those who meet here fifty years hence will then speak of that motor except in the character of a curiosity to be found in a museum"; such was the overwhelming opinion he had formed regarding the internal combustion engine. While the steam engine, including the steam turbine, has found success in certain definite fields of application, as has its rival in others, it cannot be denied that the internal combustion engine has, due to its special advantages, opened up fields of application, not closed to but only remotely accessible by the steam engine. Of these the highest is that of aeronautics, in which the present-day performance of the engines in use is such as Bramwell could not have imagined.

The first of these three lectures was in the nature of a general survey, outlining the development of the various types of engine as regards combustion, materials and manufacture. It is only in the last twenty years or thereabouts that the processes of combustion in petrol engines have been elucidated. Such well-recognized phenomena as 'pinking' and 'knocking' were known to be of importance in practice, but only the vaguest ideas were prevalent regarding the conditions which give rise to them. Although finality has by no means been reached, the systematic investigations of Ricardo and others have given the engine designer a sound basis on which to work.

In the compression-ignition type of engine, the development of 'airless' injection has been the most important improvement in combustion processes, as the resulting simplification of the engine has extended its field of application and given an impetus to its further improvement. Striking developments have also taken place in the materials used in their construction and in methods of manufacture, with great advantages in the reduction of weight relative to power.

The steadily increasing speeds at which internal combustion engines are now designed to operate has led to a virtual modification of the working cycle from the constant-pressure combustion proposed by Diesel to one approximating more closely to the constant-volume combustion of the petrol engine. In the petrol engine the direct injection of the fuel avoids the loss which otherwise occurs during the scavenging process in the two-stroke cycle and has opened up a wider field for this type. Prof. Davies expressed the view that the development of two-stroke petrol engines for aircraft appears to be within the range of practical possibility, and that, given success in this field, the extension of two-stroke working to all forms of petrol engines used in transport may be only a matter of time. Discussing the relative merits of carburation and fuel injection for aircraft engines, he gave it as his opinion that, if the two systems had started together forty years ago, fuel injection would have been in universal use to-day. The secret development work done by the Germans to make fuel injection satisfactory has enabled them to use it in all their fighter and bomber aircraft. Given a satisfactory arrangement of the controls, it offers the advantages of elimination of freezing, better distribution, low consumption at reduced brake mean pressures, lower hydraulic resistance in induction by the absence of choke and the possibility of two-stroke working.

An interesting comparison was made between the Rolls-Royce Merlin and a captured Daimler-Benz engine. Both develop practically the same power at take-off, but as the former is 27 litres against 33·9 of the German and their respective speeds are 3,000 and 2,400 r.p.m., the specific rating of the British engine is much higher. The Rolls-Royce has a two-speed drive to its supercharger, while the Daimler-Benz has an infinitely variable hydraulic drive which permits of the speed and therefore the charge being suitably adjusted to altitude. Prof. Davies stressed the need for improved superchargers and scavenging pumps, as increased efficiency of these gives the advantages of reduced power required to drive them, lower cycle temperature with increase of charge density and of volumetric efficiency.

A type of engine of which little has been heard in Great Britain is the coal-dust engine, a point of some importance since British coals are more suitable for the purpose than those found in Germany, where development work has been done on this type. Diesel himself originally proposed such an engine but was unable to make it practicable. The Schichau Company of Elbing has carried out researches on a single-cylinder engine developing 160 h.p. at 200 r.p.m. Commercially, it has found the delivery of coal-dust ready for use direct from the mine in trucks to be most suitable, and the special removal of ash from the coal-dust to be uneconomical. Ignition temperatures vary from 300° C. for lignite to 600° C. for anthracite. The dust is used in the same fineness as for boilers, finer grinding being unnecessary as only 2 per cent in calorific value is lost to exhaust.

An auxiliary ante-chamber attached to the cylinder serves as a lock in free communication with the cylinder, and the fuel is admitted to the lock chamber by the fuel valve during the later part of the suction stroke, at the end of which the valve closes. During the instroke, compressed heated air is admitted and partial combustion occurs in the lock chamber as top dead-centre is reached. The resulting excess pressure in the chamber evacuates the contents into the cylinder during the expansion stroke. A continuous brake thermal efficiency of 25 per cent has been attained, but the main difficulties include wear of cylinder liner, wear, leakage and fracture of piston rings, pitting, erosion and sticking of the fuel-valve, and burning and erosion of the ante-chamber nozzles.

Concluding with some remarks on future developments, Prof. Davies pointed to the importance of research. For the last Schneider Trophy races the improvements in the aerodynamic properties of the aircraft and in the performance and reliability of the Rolls-Royce engine were obtained from comparatively modest outlays privately provided. Such an example shows the vast possibilities of well-directed research, and the reward of funds provided for the purpose.

FORTHCOMING EVENTS

Tuesday, April 22

Institution of Civil Engineers (Road Engineering Section) (at Great George Street, London, S.W.1), at 5 p.m.—Mr. Arthur John Hamblin Clayton: "Road Traffic Calculations".

Wednesday, April 23

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Prof. T. Neville George: "The Development of the Towy and Upper Usk Drainage Pattern".

Friday, April 25

Institution of Mechanical Engineers (at Storey's Gate, London, S.W.1), at 2 p.m.—Mr. G. E. Windeler: "Mechanical Mishaps".

North-East Coast Institution of Engineers and Shipbuilders (at the Mining Institute, Newcastle-upon-Tyne), at 6.45 p.m.—Prof. J. F. Baker, and Mr. J. W. Roderick: "Plastic Theory: its Application to Design".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Graduate Teacher qualified in Electrical Engineering in the Blackburn Municipal Technical College—The Director of Education, Education Offices, Library Street, Blackburn (April 23).

Chief Education Officer to the Darlington County Borough Education Committee—The Chief Education Officer, Education Office, Darlington (April 28).

Woman Graduate Lecturer in Education at the Bingley Training College—The Education Officer, County Hall, Wakefield, Yorks. (May 2).

Assistant to the Director of Education with special reference to Elementary and Secondary Education—The Director of Education, Education Offices, Leopold Street, Sheffield 1 (May 3).

Civil Engineering Assistant to the Tees Valley Water Board—The Engineer and Manager, Water Board Offices, Corporation Road, Middlesbrough (May 5).

Research Officer in the Mental Disease Research Department—The Secretary, The University, Edmund Street, Birmingham 3 (May 16).

Reader in Pharmacology—The Secretary, The University, Edmund Street, Birmingham 3 (June 1).

Assistant Engineer for the Sudan Government Railways—The Controller, Sudan Government London Office, Oxford Hotel, 261 Clifton Drive South, Lytham St. Annes, Lancs. (quoting 'Assistant Engineer').

SCIENTIFIC ADMINISTRATION IN NATIONAL AND LOCAL GOVERNMENT

THE attack on the Civil Service launched by Lord Percy in the House of Lords recently, is only one among many indications of disquiet about the efficiency of national administration in a democracy in times of peace as well as in the stress of war. It is not only from the national point of view, however, that the question of government and administrative efficiency is being raised anew. Just as in the national sphere we are being forced to consider the limitation of national sovereignty and even the transfer of certain powers to a federation if world order is to be established, so within the nation we are being forced to reconsider the units of local administration. The forces which in certain fields of public service were already making for regionalism have been powerfully reinforced by the exigencies of war. Under its influence and that of the regional organization developed for civil defence, the character of local government is being profoundly modified. Not only its efficiency but also its scope and character are coming in for reconsideration and development.

These circumstances give pertinence to a number of studies of public undertakings which have appeared in recent years. We have had, for example, "Public Enterprise", a series of studies of developments in social ownership and control in Great Britain, covering the Port of London Authority, the Forestry Commission, the British Broadcasting Corporation, the Central Electricity Board, the London Passenger Transport Board, the Post Office, and others, edited for the New Fabian Record Bureau by Dr. W. A. Robson. Mr. T. H. O'Brien's "British Experiments in Public Ownership and Control" is one of a new series of studies under a recent scheme promoted by the Institute of Public Administration, and confines itself to the Central Electricity Board, the British Broadcasting Corporation and the London Passenger Transport Board. Dr. W. A. Robson's "The Government and Misgovernment of London" is a further important contribution, while still more recently, in "Advisory Bodies : a Study of their Uses in Relation to Central Government", by the Oxford University Politics Research Group, we have a careful examination of an instrument to which much importance was attached by Lord Haldane in the Machinery of Government Report.

One of the most difficult questions, and one which is at the same time closely related to the problems of regionalism, is that of municipal trading, examined by Dr. Herman Finer in a recently published volume.* Concentrating his attention on the four main municipal undertakings—electricity, gas, transport and water—he discusses the various theoretical problems raised by municipal enterprise, a brief survey of the historical development of municipal trading being followed by an account of the legal framework.

The main interest of this study at the present time lies in those parts of the second book, concerned with factors in production, which deal with administrative organization and personnel and with the size of the undertaking, and in the concluding observations on the balance of deterrents from, and incentives to, efficiency, and the factors of success and their development which comprise the fourth book.

Dr. Finer's principal criticism of the administrative organization relates to the size of the managing committees. The large membership is required because the committees in charge of undertakings are representative of the council, and the council representative of the electorate is not conducive to a high degree of responsibility. Control of public enterprise tends to be anticipatory, to avoid the errors which have been seen to occur in private enterprise. On the other hand, it is recognized that the greatest single decision which a committee can make is the choice of its technical chief. Upon his expertness, and, just as much upon his character as an administrator and vision as a business man, the solvency and service of the undertaking depend; and generally speaking the committee is regarded as responsible for policy, while the manager is responsible for administration and is given a free hand in the planning of development and the execution of policy.

---

* Municipal Trading : a Study in Public Administration. By Dr. Herman Finer. Pp. 432. (London : George Allen and Unwin, Ltd., 1941.) 16s. net.

The conclusion is reached that, with few exceptions, municipal undertakings in Great Britain are efficiently administered, but while the weak spot of anticipatory control is referred to, insufficient stress is placed upon the extent to which conditions to-day are demanding a more dynamic and creative type of administration. These demands are made both in the field of policy and in that of day-to-day administration, and the extent to which war conditions have revealed the shortcomings of those who are merely capable of routine administration, only accentuates a weakness which was already becoming apparent in local and national administration in time of peace. It will no longer be sufficient for municipal undertakings to demonstrate their capacity for routine administration. They must show now that they also possess wide vision and powers of innovation and creative development—the power to see the services for which they are responsible in terms of wider national needs, and the capacity to judge between conflicting views of the public interest in those services.

It is the great merit of studies of the character of Dr. Finer's survey that they bring to light inherent weaknesses and facilitate the provision of correctives. The healthiest single factor in the success of municipal undertakings, he points out, has been direct democratic control, and for this reason he would deprecate any reorganization of these utilities on the lines of the semi-public corporation, of which he is severely critical, owing to its remoteness from control by the consumer. The development of that task of adult education in citizenship, and particularly in the functioning of, and application of, democratic methods upon which the continuance of genuine and efficient local government really depends, is calculated in itself to stimulate the provision of both a better type of councillor and committee man, and the supply of officials of the highest administrative capacity.

The technical officers are of critical importance. They, after all, are members of a profession, and for all save the very exceptional men will be limited by the general standard of their profession, just as that standard from another point of view ensures the maintenance of a high standard of efficiency. It is a welcome sign that professional men are increasingly taking an interest in the wider horizons of their profession and in the relation to post-war reconstruction, as indicated by Sir John Orr's address to the British Medical Association, Prof. A. V. Hill's address to the Parliamentary and Scientific Committee (see NATURE, March 1, p. 250), and Dr. John V. N. Dorr's address as Perkin medallist of the Society of Chemical Industry on the engineer and his responsibilities to the world of to-day and to-morrow.

It is only as the scientific worker and other professional men no longer content themselves with the easy task of criticizing the routine and timidity of civil service administration, but accept their own wider responsibilities and attempt to make positive contributions to the development of administrators characterized by creative ability and the capacity to promote energetic and far-reaching projects, and seeing opportunities rather than difficulties, that we can hope for advance. The administrator, whatever his professional origin, who is to use his opportunities to the full and carry with him those whose vision is narrower and who are less willing to co-operate or to take risks, needs not only the assurance of professional tradition but also the inspiration of professional ideals. Much might yet be done, even in its present form, to raise the outlook and character of local government and administration and to stimulate co-ordination, regionalism and the reorganization of areas, if the technical officers in municipal undertakings had the support of a wide and generous outlook and understanding from their professional associations.

Among the suggestions which Dr. Finer advances for improvement in the efficiency of municipal enterprise is steadfast and determined attention to the selection of officers of all grades. He advocates a much severer probation, and that technical officers as well as the administrative and clerical staffs should be compelled to take some such course as that prescribed for the diploma of public administration instituted at various universities. Those managing undertakings must learn to appreciate their strength, and also the weaknesses against which they must continually pit their determination, so that they may be equal to the even severer demands which the necessary co-ordination and reorganization of areas will involve.

The possibilities of interchange of staff mentioned by Prof. A. V. Hill in his address referred to above, should also be given serious consideration. If we could once more stimulate the exchange and movement of technical and scientific workers between Government departments, local authorities, the universities and industry itself, the advantages in creative work as well as administrative outlook and efficiency would be far-reaching, from the scientific, technical, social and national point of view. The value of thus stimulating creative thought and checking departmentalism should make well worth while the effort required to develop a uniform pensions scheme, calculated to assist and encourage mobility whether between Government departments, the local government services, the universities or even industry. Even if the attempt can only be made over a part of the field, co-operation between Government service and the universities as suggested by Prof. Hill is a promising line of advance. Moreover, the wider experience and outlook which flow from increased mobility should assist to throw up administrators of the type so urgently required. Local government services have in fact done little to implement the findings of the Hadow Committee, nor have such public corporations as the British Broadcasting Corporation, the London Passenger Transport Board or the Central Electricity Board realized the possibilities which are before them of handling staff problems so as to develop an administrative service free from even the defects for which the Civil Service has been criticized.

FORESTRY ADMINISTRATION

Colonial Forest Administration

By Prof. R. S. Troup. Pp. xii+476+32 plates. (London: Oxford University Press, 1940.) 35*s*. net.

FORESTERS throughout the Empire will be glad to learn through the publication of this book that Prof. Troup was just able to complete this important work, which it was generally known he had in hand, before being struck down by the illness which proved fatal; from the prefatory note we learn that it fell to Mrs. Troup and Prof. H. M. Steven to see it through the press. One can confidently say that no one, but Troup with his exceptionally wide experience and clarity of thought and expression, could have written it. For both presentation of subject and printing we have nothing but praise, and do not remember ever having read through a book of 450 pages on forestry which revealed so few points calling for criticism. There may be, however, one rather fundamental doubt about it, and that is whether, in view of the public for which the book is stated to be written, namely, probationers and officers of the Colonial Administrative Service, it is not too lengthy and too expensive. The cost and length will, we believe, prevent its purchase by a large number of potential readers who would find it of great interest and value; it is too good a book to be referred to occasionally in the library, and but for these difficulties should surely find a place on the private bookshelf of all foresters and others interested in forestry.

The preface explains how the subject-matter of a short course of lectures has come to be expanded to so solid a volume, but we feel that a significant amount of the more technical aspects of forestry, such as a discussion of the mean and current annual increment and details of working-plan procedure, could have been omitted, though their inclusion undoubtedly results in the presentation to the administrator of a more finished picture of forestry in general. As it is, it can confidently be asserted that no colonial administrator or forester can read the book without finding a great deal of useful information new to him, whilst some of the surveys such as those on the effects of forest destruction and on the character and distribution of forests are masterpieces of skilful compression; the explanation of a working plan and sylvicultural systems is equally good. The book as a whole also answers extremely well the common query: "What does a forester do?"

The book is divided into two parts. Part 1 deals on broad lines with all the major heads of forestry, such as the influence of forest on climate, soil erosion, the effects of forest destruction and measures for protection, forest reservation, State control, etc. Part 2 takes the units of the Colonial Empire in turn and describes the major points of policy and administration in each.

A few points noted during perusal of the book may be mentioned. In Section (? lecture) VI, the account of cover crops for soil conservation is perhaps not altogether up to date and the impression is wrongly conveyed that *Tephrosia candida* is a small tree similar to *Leucœna glauca*. The importance of growing the most suitable variety or strain of seed requires mention either in this Section, as for *Prosopis glandulosa*, or in that on plantation work (XII) as for teak.

In Section VIII, a point that might have been more stressed is that the clearing of good forest in the tropics by no means necessarily gives good agricultural land.

In Section IX, as an important point in practice, rather more might have been said on one of the indirect effects of uncontrolled grazing, especially of goats, and that is the intensive lopping which always accompanies it, leading to selective extermination of fodder species. More might have been said of the experiments of recent years under the head of seasonal closure when at least part of an area must be kept open at any given time. So important is the warning that undue multiplication of stock must be prevented before it is too late that one would have liked to see it more heavily underlined; unfortunately the usual history is that no effective action is taken by the administrator on the forest officer's continued complaining until control has become far more difficult and unpopular than it would have been had the trouble been nipped in the bud. Declaration of grazing policy is a sound measure, but critical examination of the Central Provinces, India, the example quoted, would reveal its very weak spot of accepting a very bad *status quo* in overgrazed forests.

In Section XI, recent very successful extensions of the *taungya* method in thickly populated tracts, often with the primary object of meeting villagers' needs even for tree loppings, might have been referred to as a possible pointer for future development.

In Section XII, the data for employment given by forest operations are useful as also the demonstration of the magnitude of the demand on the forest of factory or mining activities. It is pointed out that where denudation is rampant the pinch first comes in a shortage of fuel: this might have been developed with the common picture of the fields being deprived of cattle manure because this is the only available substitute for wood fuel. In Section XIII, on forest exploitation, the author repeatedly emphasizes the importance of pushing the use of second-class timbers, a step the need of which is almost universally felt in the more extensive forest tracts and must be given the closest attention. In Section XIV, dealing with ownership, etc., one would have liked some indication of the extent to which laws concerning forest control on private land have actually been acted on.

We feel that a note of warning on the risks involved in settling forest villages would have been in place in Section XV. Instances could be quoted where, for whatever reason, the forest work which it was intended to do through their agency has not been properly done and the land occupied has ultimately been excised from the forest to form a centre of all the usual troubles over grazing, lopping, felling and fire damage that are characteristic of squatters' settlements in the middle of a forest. The figure given for the annual shifting cultivation area in Nigeria will come as a surprise and a shock to many.

In Section XVI, it is pointed out that the South African gold mines need the produce from 100,000 acres of plantation annually, but one misses an explanation as to how this huge demand is being met at present.

Section XIX, dealing with administration, includes a note of warning which will be endorsed by many practising foresters, against undue specialization in the earlier stages of development. The first duty of a young or small department is to give the forests in its charge really effective protection and simple conservative management.

Section XX deals with education and research. Every forest officer who has been in India knows how much of the executive work is done by the trained subordinate staff, particularly the rangers, and Troup finds repeated occasion to rub in the importance in various directions of building up a similar staff in the Colonial Dependencies.

The accounts in Part II of the forest policy and position in the several colonies give a historical account of the forest administration leading up to the current policy; this is followed by a summary of the procedure for reservation, which is frequently influenced by differences in form of ownership of the land, and concludes with area statistics. These accounts, of which there are as many as twenty, vary in length from 3 to 10 pages, not necessarily in proportion to the area of forests, and will be found exceedingly useful for reference.

Finally, there are five appendixes which are also very welcome as collecting information hitherto not readily available on forests and water supply, forestry in relation to tsetse fly control, legislative and administrative action taken in regard to protective forestry, colonial mining laws and timber rights, and a list of colonial forest laws.

The forty-four half-tone reproductions of photographs used to illustrate the text are very well selected and of a standard one has come to expect of Troup and the Oxford University Press.

H. G. CHAMPION.

THEORY OF KNOWLEDGE

The Analysis of Knowledge

By Prof. Ledger Wood. Pp. 264. (London: George Allen and Unwin, Ltd., 1940.) 12*s.* 6*d.* net.

THIS work on the theory of knowledge has distinct merits. It is well arranged, well written and discusses all the subjects that should be discussed. The author deals with sense experience and memory, perceptual knowledge of 'things', of our own selves and other persons, the generalized knowledge of science and the knowledge implied in judgments of value. However, the book as a whole is disappointing.

In treating of perception the author criticizes the 'sense-datum' school of writers on grounds that certainly do not apply to Broad or Price. His own theory seems to be just the sense-datum theory with a slight change in terminology. He takes no account of what Gestalt psychology has to say about the objects of experience, and does not mention the important discussion in Blanshard's "Nature of Thought". He emphasizes at the beginning that all thought is referential, pointing to something beyond itself. One would suppose that this implied that relations are as real as any of the terms they relate, yet in Chapter vii he maintains that universals, including of course relations, are concepts, in the sense of being mental entities having no reference to anything beyond themselves. Worse still, in the last chapter he states a correspondence theory of truth, which implies a realist view of universals, since, as he says, truth is a property of propositions and since every proposition contains at least one universal term.

The best and most original feature of the book is the chapter on valuational knowledge, though it is confined to ethical judgments. The author perhaps makes undue use of the ambiguity of the term 'ideal', but he deserves credit for realizing that, however naturalistic a theory of knowledge may be, it cannot exclude value judgments, and for an ingenious method of including them.

If Prof. Wood could be induced to accept a realist view of universals (under the guidance of Peirce, Russell or Whitehead) to clear up some minor inconsistencies and to consider what Köhler and Blanshard have to say about facts of experience (only authors resident in his own country have been named), there are here the elements of a valuable theory.

AIR NAVIGATION

The Observer's Book on Astro-Navigation

By Francis Chichester. Part 1. Pp. 103. Part 2. Pp. 83. (Observers' Books, Nos. 3 and 4.) (London: George Allen and Unwin, Ltd., 1940.) 2*s.* 6*d.* net each.

IT is commonly thought that the determination of the position of a moving aircraft by means of astronomical observations is a difficult and complicated business. Actually, the principles involved are of extreme simplicity, and the working out of the observations takes at the most a few minutes with the aid of the *Air Almanac* and suitable altitude-azimuth tables to provide the solutions of the spherical triangles.

The observation of the altitude of a celestial body places the observer on a small circle, the centre of which is at the point on the earth's surface that has the body in its zenith at the instant of observation, and the radius of which is the complement of the observed altitude. The portion of this circle in the vicinity of the observer's position can be regarded as a straight line, and is known as a position line. The intersection of two position lines, allowance being made for the motion of the observer between the two observations, fixes the observer's position.

To draw the position line, any convenient position for the aircraft, somewhere near its estimated position, may be assumed. The position line will be independent of the assumed position. The surface navigator has been tied for too long to his dead reckoning position, which has no special virtue. In air navigation, an assumed position is adopted such that the altitude-azimuth tables require no interpolation. With the aid of the *Air Almanac* and the *Astro-Navigation Tables*, both prepared by the Nautical Almanac Office for the Air Ministry, the reductions are reduced to their simplest possible forms.

In these two small volumes, by an experienced air navigator, the methods and principles involved are explained in clear and simple language. Specimen pages from the *Air Almanac* are reproduced and their use is described. A number of hypothetical observations (for which the astronomical data can be obtained from these pages) are fully worked out to illustrate the methods, according as observations are made of stars, the Pole star, planets, the sun or moon. The principles of the bubble air sextant are explained and the methods of observation are described.

These volumes are eminently practical and can be strongly recommended to all navigators. They can be read in an hour or two and should help to dispel the mistaken belief that there is anything mysterious or complicated in the principles and methods of air navigation. H. S. J.

THE TEACHING OF BIOLOGY

(1) Animal Biology

By Robert H. Wolcott. (McGraw-Hill Publications in the Zoological Sciences.) Second edition. Pp. xxi + 649. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 24*s*. 6*d*.

(2) Human Biology

By Prof. George Alfred Baitsell. (McGraw-Hill Publications in the Zoological Sciences.) Pp. xv + 621. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 26*s*.

(1) THE basic themes around which this course in zoology is built are: life as a chemicophysical basis and life as a manifestation of metabolism. The choice of title is a happy one, for the course here devised is truly a biological one, and should cause most authorities responsible for general university degree courses in Great Britain to think whether their teaching is not too much based on systematics and type systems, at the expense of animal physiology.

Having got a course in animal biology (as opposed to zoology) it is not a very far cry to general biology; since Prof. Wolcott has proved possible, and even desirable, a course in animal biology up to university degree standard, it should be no more difficult to devise a course of the same standard in general biology—a course of study which is practically non-existent in Great Britain. Indeed, even in this avowedly "Animal Biology" the author has recourse to plants in such topics as tropisms, photosynthesis, alternation of generations, etc. Maybe the day will come when students in all universities can take a degree course in general biology, instead of the present botany and/or zoology courses. Until that day comes, there will perforce be a lack of good teachers of biology in schools, with the consequent backward condition of the teaching of the subject. It is surely a reflection on our system of teacher training that even now many teachers of biology in schools have either not qualified in the subject or are specialists in botany or zoology, and consequently either biased or ill-informed, or both.

At this stage, therefore, we would strongly recommend all students of zoology and certainly all teachers of biology to read Prof. Wolcott's book. Though he does not ignore zoological 'types' altogether, he does, on the other hand, lay special emphasis on general, comparative and economic aspects under such chapter headings as: energy, protoplasm, metabolism, plants and animals, behaviour, Protozoa and diseases, tissues, fertilization, reflex action, anthropoid apes and man, structure of organisms, developments, ecology, animal organisms in health and diseases, and so forth.

(2) Prof. Baitsell's book strikes an even more novel note, basing an introductory study of biology on a study of man himself. The author's reason for such a course is sound, being based on "the increasing realization . . . that the majority of students beginning work in college biology were, inherently, far more interested in acquiring knowledge about the human organism than they were concerning any other living species". We believe this to be true in the majority of cases.

Here again, plant biology is utilized in the study of certain aspects of the subject. The text is by no means medical. It is a real biology with man as the main 'type', though others are frequently called upon, for example, the development of the frog, chick, other mammals, in leading up to growth and reproduction in man.

There are an interesting chapter on disease and a very extensive appendix of ninety-three pages which will do much to prevent the student's thoughts being devoted solely to man. The appendix is unusual in being arranged alphabetically in encyclopædia fashion. It deals with such diverse subjects as acetylcholine, Amœba, Aristotle, biology of medicine, Brownian movement, colloids, diffusion, germ plasm, taxonomy, history, pneumonia, etc.

Both these books are by American biologists and therefore might with advantage be consulted by British students and teachers, since biology is an academic and cultural subject of study and has made greater progress in the United States than in Great Britain. But the live British biologists are aware of our shortcomings and will welcome the aid offered by such as these books.

Kungl. Svenska Vetenskapsakademien:

Förhistoria, Grundläggning och Första Organisation. Av Bengt Hildebrand. Pp. xv+672. Noter, Bilagor M.M. Pp. v+673–886. (Stockholm: Kungl. Svenska Vetenskapsakademien, 1939).

In these two volumes, Dr. Hildebrand gives an account of the inception, foundation and early years of the Royal Swedish Academy of Sciences, which is now two hundred years old. Already in the seventeenth century the spirit of research in the natural sciences was afoot, and the tendency to do away with Latin in place of the worker's national language was gaining ground. There was, however, a strong utilitarian bias in scientific work. The Royal Society of London and the Academy of Science of Paris showed the way to pure research. The foundation of these and later that of the Academy of Science of Russia prepared the way in Sweden. A few attempts to found learned societies failed, for the universities still were dominated by the dead languages, but in 1728 the Royal Society of Sciences was founded in Uppsala. About the same time the capital saw the start of academies of music, painting and literature, and in 1739 the Academy of Science was founded on the model of the Royal Society and the French Academy of Science; two years later it received a royal charter.

Among the founders was Linnæus, who became its first president. The early bias of the academy towards economic problems was not maintained beyond the beginning of the nineteenth century, and up to that time much attention had been paid also to work in mathematics and natural science. In 1813 agriculture founded its own academy, and under Berzelius the Royal Swedish Academy devoted itself more and more to natural science, giving up humanistic and practical studies.

Dr. Hildebrand traces in detail all these changes and the background against which they took place, and he gives a long account of the work of all the founders, as well as the original constitution and descriptions of the library and museum. There is an exhaustive bibliography on all aspects of the work.

R. N. R. B.

Analytical Processes:

a Physico-Chemical Interpretation. By Dr. T. B. Smith. Pp. viii+470. (London: Edward Arnold and Co., 1940.) 18*s*. net.

During the past ten years, many important advances have been made in physical chemistry, and it is not surprising, therefore, that a new edition of Smith's "Analytical Processes" has now made its appearance. This new edition incorporates recent developments, and some sections of the first edition dealing with fundamental relationships have been dropped.

To appreciate this book fully, the reader must be fully conversant with the basic principles of physical chemistry, and the volume is therefore of particular value to senior students or to those making physical chemistry their special study. The author's object is to give full scientific explanations of the theories underlying analytical processes, since only those who have a thorough knowledge of such theory can ever approach, with any hope of real success, the many new problems arising in the examination of minerals and of new industrial products. Further, such knowledge is essential when sources of error in analytical processes have to be elucidated, minimized or removed.

This authoritative and advanced treatise is indispensable not only to those who are engaged in a university course, but also to technical chemists whose duties lie in industrial chemical analysis.

Practical Histology and Embryology

By Dr. Nellie B. Eales. Pp. xi+111. (London: Macmillan and Co., Ltd., 1940.) 3*s*. 6*d*. net.

This little book provides an excellent guide to practical work for first-year students in histology and vertebrate embryology. Dr. Eales is an experienced and successful teacher and knows well the pitfalls that lie in the way of the beginner. The simplest methods and a small number of fixatives and stains have been chosen out of the bewildering variety that are at the disposal of the more advanced worker. Directions are given for preparing simple histological injections and for the elementary technique of mammalian embryology, both of which are usually omitted from the first-year course. It may perhaps be suggested that the simplification of methods might perhaps have been carried a little further with advantage; that rough hand-cut sections might have been substituted oftener for the more elegant products of the microtome. Many beginners, and even some more advanced students, have great difficulty in relating the two-dimensional picture presented by a microtome section to the three-dimensional structure of a tissue or an embryo. Sections cut, however inexpertly, by the student himself, do help him over this difficulty.

Very few slips have caught the eye of the reviewer, but Canada balsam is not crystalline (p. 6), nor are teeth "epidermal products" (p. 63).

W. T. Calman.

Modern Diagnosis

Edited by Sir Humphry Rolleston and Dr. Alan Moncrieff. ("The Practitioner" Handbooks.) Pp. 286. (London: Eyre and Spottiswoode (Publishers), Ltd., 1940.) 12*s*. 6*d*. net.

The editors are to be congratulated on the choice of the twenty contributors to this volume, which consists of two parts, the first dealing with clinical diagnosis and the second with laboratory and special diagnosis. With the exception of an article specially written for the book by Dr. C. J. C. Britton on the technique of simple blood examinations and methods for collection of blood, all the contributions have previously appeared in the *Practitioner*, but have been revised and brought up to date. Although the work covers a wide range of subjects including neurology, dermatology, cardiology, pædiatics, gastro-intestinal disease, diabetes and chronic rheumatism, it makes no claim to discuss the whole field of medicine, but deals only with those subjects in which diagnosis is most difficult.

The book, of which the text is liberally interspersed with illustrations, is admirably suited for the general practitioner and senior student.

THE STUDY OF LAKE DEPOSITS

BY B. M. JENKIN, C. H. MORTIMER AND W. PENNINGTON,
FRESHWATER BIOLOGICAL ASSOCIATION, WRAY CASTLE, AMBLESIDE

LAKE deposits have proved to be of interest in various ways. They present convenient material for the study of the process of sedimentation and of the initial stages of sediment metamorphosis. They remain for long periods uninfluenced by erosion, weathering and other disturbances, and preserve in stratigraphical sequence such animal and plant remains as resist decomposition, and also the inorganic portion of the parent material. They record in varying completeness and detail the biological history of lakes and the climatic conditions in which sedimentation occurred.

In general the natural evolution of a lake is towards greater productivity associated with changes in the species composition of the phytoplankton[1]. In some cases this evolution may be recorded in the deposits in considerable detail. For example, striking changes accelerated by sewage pollution, occurring in Lake Zurich have been recorded and can be accurately dated in the deposits[2].

Climatic conditions may be recorded in a general way by the presence of some organisms, for example, plankton and tree pollen, which are indicators of definite climatic types. Late glacial sediments sometimes record climate in greater detail. De Geer[3] has successfully substantiated the hypothesis that the laminations (varves) in late glacial clays represent annual cycles in the deposition of silt carried by glacier streams into still water. Thicker layers of coarser particles correspond to floods produced by rapid summer melting, and the finer layers, alternating with these, represent winter sedimentation. Careful and detailed correlation of sections of varve deposits from a great number of localities in Fenno-Scandinavia led to the establishment of a detailed climate chronology for the late-glacial period of ice recession in that region. It was possible to connect this with recent time by the study of the deposits of Ragunda lake in northern Sweden. These deposits present a fairly complete series of annual laminations from the time when the ice sheet retreated northward from that lake until 1796 when the lake was accidentally drained. This period, which the latest estimates put at close on nine thousand years, may indicate the order of magnitude of the period during which post-glacial sedimentation has continued in the British Lake District and Scottish Highland lakes.

In Great Britain little work has been done on these interesting lines of investigation until the last few years, during which the deposits of Windermere and other waters of the Lake District have been studied by the Freshwater Biological Association. In an earlier communication[4] the value of echo-sounding apparatus for the survey of certain types of lake deposit was demonstrated, and now this is followed by an account of work on cores of Windermere deposit obtained with new apparatus. In the initial stages of this work, one of us (C. H. M.) obtained cores with a simple steel pipe operated from a boat and driven in by a ramming weight. These cores showed the zonation of laminated clays and organic layers, indicated in core *A*, Fig. 2, and the diatoms (examined by W. P.) exhibited an interesting succession. We are grateful to the Royal Society for a grant enabling this work to be continued with improved apparatus.

THE CORE-SAMPLER

In spite of its simplicity, an open-ended sampling pipe used for obtaining cores has disadvantages which have been previously discussed by Jenkin and Mortimer[5]. Some other types of core-sampling gear were briefly described and the working principles of an improved apparatus (designed by B. M. J.) were outlined in the same communication. This apparatus in modified form has now been successfully operated in Windermere, and cores of up to 6·5 m. in length have been obtained under 65 m. of water.

The core-sampler, illustrated diagrammatically in Fig. 1, is operated from a pontoon held in position by four anchors and consists of the core-cutter (*A,A'*), extension tube (*B*) and turning gear (*C.C*). The core-cutter, previously described in more detail[5], consists of an outer casing in the form of a tube, part of which is cut away and replaced by a flat face-plate, and an inner half-tube (the cutter). This is supported on a shaft, the rotation of which causes the cutter to pass out through a slit at the side of the face-plate, cut into the deposit and enclose a sample 1·25 m. long. As this operation is performed after the core-cutter has been lowered to the required depth in the deposit, and as the cutter follows a horizontal circular path into undisturbed deposit, distortion of the sample is reduced to a negligible minimum. The practical operational details are concerned with ensuring that the core-cutter is exactly at the required depth in the deposit, and with cutting out the sample and removing it for examination.

A sounding wire (*D*) passes over a pulley at the top of a vertical metre scale. The sampler is suspended by the hook (*E*) at the end of the cable from a crane. The extension tube (*B*), which is 15 ft. long, is connected at one end to the core-cutter and carries the turning gear at the other. The turning gear consists of a pair of skew-gear wheels, one of which is keyed to the vertical shaft which passes down through the extension tube and is coupled with the core-cutter shaft. The other wheel is mounted on a short horizontal shaft, which carries a grooved disk (*C*) at either end. Metal blocks (*F,F*), attached to the free ends of a wire bridle, fit into notches, one in either disk. Turning the disks counter-clockwise, with the blocks in the notches, winds the bridle on, rotates the shaft and turns the inner tube of the core-cutter back inside the casing (open position *A*).

SAMPLING OPERATION

The sounding wire is paid out until the weight rests on the bottom. The pivoted swing-arms (*G,G*) are locked by the trip-bolt (*H*) with their free ends embracing the sounding wire, but allowing it to pass freely between them and through the middle loop (*I*) of the turning gear bridle, which is also held between the ends of the arms. The sampler is then lowered by the crane until the swing-arms, which slide down the sounding wire as a guide, are felt to hit the stop (*J*) which has been so adjusted that the bottom of the core-cutter is at the mud surface at this point. Penetration into the deposit is measured on the metre scale by a pointer (*K*) fixed to the sounding wire, and is halted at the required depth.

To close the core-cutter and take the sample, a messenger weight slides down the sounding wire, strikes the trip-bolt (*H*), releasing the swing arms which are pulled to the open position (G′,G′) by rubber bands. The sounding wire is now pulled up and, as the loop (*I*) rests on the stop (*J*), this withdraws the bridle, turns the disks clockwise and closes the core-cutter (*A*′).

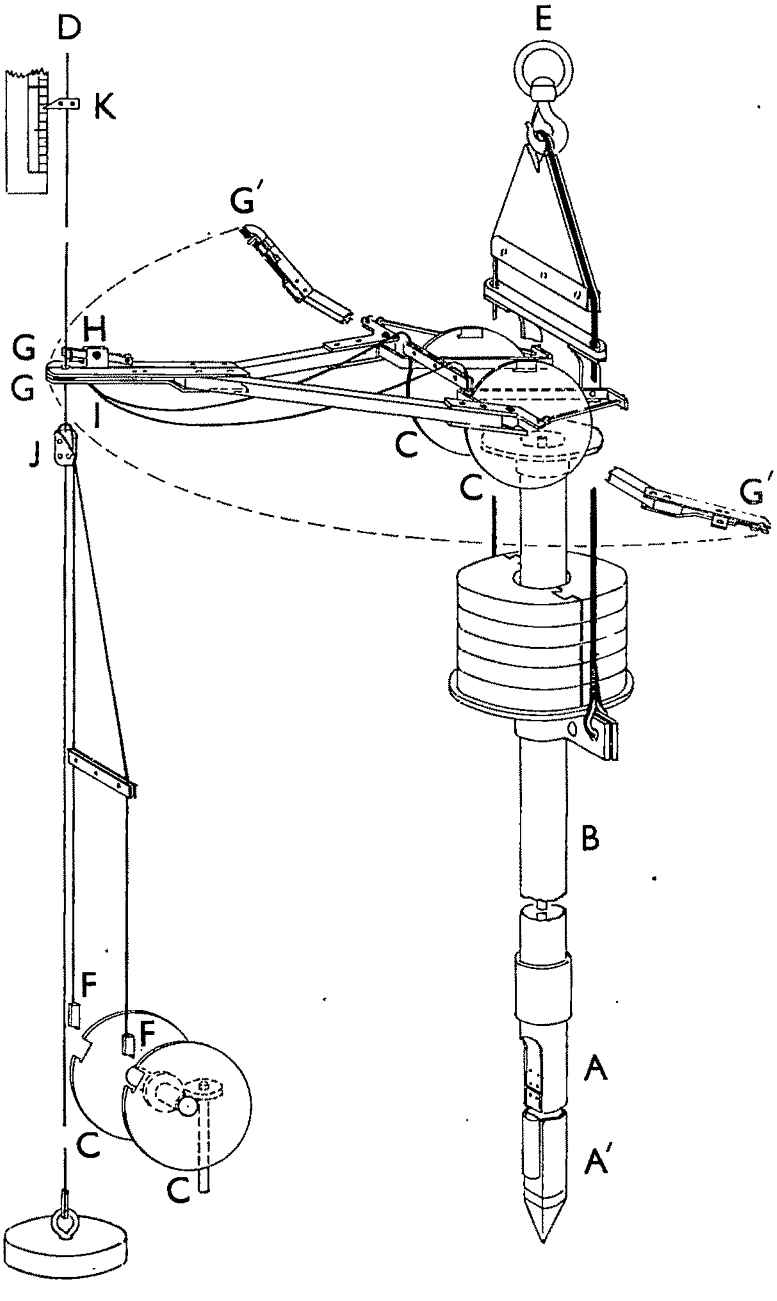

Fig. 1.
DIAGRAMMATIC ILLUSTRATION OF THE DEPOSIT SAMPLER

When raised to the surface, the weight of the sampler is transferred from the crane to two derricks and slings by the help of which it is laid face-plate upwards on a plank fixed along the side of the pontoon. After washing the outside, the core-cutter is opened by turning the disks counter-clockwise, exposing the sample on the face-plate. A sheet-iron tray is inserted between this and the sample, which is then removed for examination.

The above operation was repeated at each sampling station to obtain an overlapping series of samples, each 1·25 m. long. The weight of the sampler alone (200 lb.) was usually sufficient to penetrate the upper 2–3 m. of deposit. For deeper samples, up to 360 lb. of extra weight was added in the form of half-disks of lead, held together by dovetail projections and placed at the top of the extension tube above *B*. In work to date, the factor limiting the lengths of core obtained was the length of the extension tube.

THE CORES

With the apparatus described above a survey has been conducted of the bottom deposits of the North Basin of Windermere. Nineteen cores have been obtained in water depths ranging from 3 to 65 metres, in addition to the cores taken with the steel ramming tube. Fig. 2 shows two typical cores, from shallow and deep water respectively.

The soft, often semi-liquid surface muds are underlain by a varying thickness of firmer, dark-brown organic deposit, here called the brown mud, beneath which is a thick layer of pink laminated glacial clay, which is present in both deep and littoral regions. As was expected from the echo-sounding records[4], the total deposit, both organic mud and clay, is much thicker in deep water than in the littoral region. In cores from shallow water of less than 10 m., in the western bays, the lowest deposit is a fairly coarse gravel, which is at the base of the laminated clay, about 4 m. below the mud surface. In the deep central region, the total length of core obtained (6 m.) just included the upper layers of the laminated clay; but cores from the southern end of the North Basin, taken in about 30 m. of water, showed that here the laminated clay is 0·7–0·9 m. thick, and is underlain by a stiff, blue-grey, unstratified clay containing gravel and fragments of shale in its lower layers. It is probable that these gravels rest on the rock surface and, with the unstratified lower clay, probably represent late glacial deposits formed during the period when the lake basin was occupied by ice. Above them lies the laminated clay, the laminations of which consist of alternate layers of coarser and finer material. These are almost certainly varves, formed in the later period when only valley glaciers remained, and water occupied the present lake basin. In several cores the upper part of the laminated clay contains layers of grey silt with organic remains (diatom shells, moss plants, and in one core, leaf fragments), in contrast to the clay itself, which is practically devoid of organic remains. These organic layers appear to represent transitory periods during the retreat of the ice, when conditions in the lake were more favourable for plant growth.

DIAGRAM OF A TYPICAL CORE FROM SHALLOW WATER AND ONE FROM DEEP WATER OF WINDERMERE, SHOWING THE DISTRIBUTION OF TWO ZONAL DIATOMS, AND GRAPHS OF WATER CONTENT AND LOSS ON IGNITION.

1, Brown Mud; 2, Zone of narrow clay bands; 3, Laminated glacial clay; 4, Diatomaceous layer in clay. Zonal diatoms: (*a*) *Melosira arenaria* cf. var. *hungarica*; (*b*) *Asterionella gracillima* + *A. formosa*. (*a* and *b* are not represented on the same scale.)

The deposits above the clay represent the Post-Glacial sediments, and it seems probable that, at least in deep water, they present a complete record of sedimentation over that period. In deep water, immediately above the laminated clay, there is a zone of 1·5 m. in which narrow bands of pink unlaminated clay are separated by brownish-grey organic deposits. These narrow clay bands show considerable local variation, but the thickest two

(1–4 cm.) are fairly constant in level in all cores from the deep area of the North Basin. All these narrow clay bands fade out laterally, and do not appear in the shallow water region, where this zone is represented only by a layer of brownish-grey silt, 5–10 cm. thick. The brown mud is 2·5 m. thick in shallow water, increasing to 4·0 m. in deep water. It is very uniform in appearance from top to bottom, and more organic than the silts between the narrow clays, but like them contains frequent narrow black or dark green layers of chlorite. In the delta region of the River Brathay, the largest river entering the lake, the brown mud is much thicker than elsewhere, and a core 5·4 m. long consisted entirely of this type of deposit.

Water content and loss on ignition are indicated in Fig. 2 for two typical cores. In the surface ooze a rapid fall occurs in water content, which was nearly 90 per cent at the surface and about 78 per cent at 30 cm. From this point downwards in the brown mud there was a gradual, somewhat irregular fall to about 70 per cent just above the clay. The density of the brown mud varied from 1·06 at the surface to 1·24 at the bottom. Variations in density may be attributed mainly to variations in water content, as the density of the dried brown mud was close on 1·6 from the top to 4 m. As might be expected, there was a sharp discontinuity between mud and clay. The top of the laminated clay was of fairly uniform water content (34–38 per cent) and density (1·70) in different regions of the lake. In the stiff unstratified blue clays, mentioned earlier, the water content fell to 24 per cent and the density rose to 1·97. Details of the distribution of loss on ignition may be seen in Fig. 2. Although irregular variations between 19–23 per cent occurred in the brown mud, there was no significant difference between top and bottom of this layer, but much lower values were found in the organic layers associated with the clays. The value for the clay was 3 per cent, which probably represents combined water. Loss on ignition in the brown mud and other organic layers may be taken as an index of organic content, as the error due to combined water can scarcely have been greater than 3 per cent.

COMPARISON OF CORES WITH ECHO-SOUNDING RECORDS

Cores were taken at or near positions for which echo-records obtained with a Husun recorder were available. Many of these records not only showed an echo from the floor of the lake, but also one or more echoes below this at distances of up to 13 m. below the mud surface. It was suggested[4] that these echoes represented reflexions from density discontinuities, such as might be expected to occur at mud-clay or clay-rock interfaces. It is now possible to compare the level of the top of the clay in the cores with the level of the first echo below the mud surface in the corresponding echo-records.

The simplest conclusion from this comparison is that the first echo below the mud surface comes from the top of the laminated clay or from the uppermost of the narrow clay bands in cores where this is well developed and more than 1 cm. thick. On this assumption, comparison between echo-records and eleven cores yields values for the velocity of sound in the brown mud which vary between $1{\cdot}54 \times 10^3$ and $1{\cdot}68 \times 10^3$ metres per second. This small variation indicates that the above interpretation of the echo-records is correct. The mean value $1{\cdot}6 \times 10^3$ metres per second or 1·14 times that in fresh water is comparable with velocities of longitudinal explosion waves found in clays and waterlogged glacial material[5]. If the velocity of sound in the laminated clay is similar to that found in the brown mud, the echo-records indicate that another density discontinuity, possibly a layer of gravel or rock, exists at 10–12 metres below the mud surface in the deep region of the North Basin.

ORGANIC REMAINS IN THE CORES

Diatom shells are abundant in the brown mud, the organic layers between the narrow clay bands, and in some of the organic layers in the laminated clay. In addition, a deposit of almost pure diatomaceous earth, 25–30 cm. thick, was found above the laminated clay in Low Wray Bay. The diatom content of all the cores has been studied, and the results show that three main phases in the past history of the lake can be distinguished.

It should be recognized that two main factors have been concerned in modification of the environment in the lake since glacial times: first, climatic changes affecting the whole region, and secondly, changes in the lake itself produced by silting and other causes. The first marked discontinuity in the cores is that separating the surface ooze from the underlying brown mud. This discontinuity occurs at 20 cm. below the mud surface in deep water, and rises nearer the surface as shallower water is approached, until it is about 5 cm. deep in water 5 m. in depth. The diatom flora of the ooze is characterized by *Asterionella formosa* Hassall and *A. gracillima* (Hantzsch) Heib. which, with *Cyclotella Kützingiana* Thwaites make up most of the diatom population. At the base of the ooze layer there is an abrupt drop in the numbers of Asterionella, which in the underlying layers becomes unimportant. According to Pearsall and Pearsall[7] a plankton dominated by Asterionella represents a late stage in the evolution of a glacial lake, and it is known that since the beginning of the present century there has been a considerable increase in the numbers of this diatom in Windermere, where the natural processes of evolution have been hastened by the increase in productivity consequent on sewage pollution. It is probable that this layer of ooze containing abundant Asterionella represents the deposit accumulated in the last fifty years or thereabouts.

The brown mud below the surface ooze has a very uniform flora, dominated by the plankton diatoms *Cyclotella Kützingiana*, *Tabellaria fenestrata*, Kütz., *T. flocculosa* (Roth) Kütz., and small littoral diatoms which are more abundant in the cores from shallow water. These species are abundant in all the diatomaceous layers, and, in numbers, make up the greater part of the diatom population throughout the cores.

On the other hand, the large and conspicuous diatom species show a marked zonation. The brown mud in all the cores is characterized by *Gomphonema geminatum* (Lyngb.) Ag. and *Pinnularia major* Kütz. These, especially the former, become less abundant with increasing depth, but there is no pronounced discontinuity in the brown mud. A very marked change occurs below the topmost narrow clay band, and in the corresponding narrow band of silt above the laminated clay in the littoral region. Here, most of the large species, except the two just mentioned, increase considerably in numbers, and two species which are absent or rare in the brown mud, namely, *Melosira arenaria* Moore *cf. var. hungarica* Pant. and *Campylodiscus noricus* Ehr, become abundant. This type of diatom assemblage is constant throughout this zone immediately above the laminated clay, and in the diatomaceous layers within the laminated clay. It therefore appears to be associated with the conditions under which glacial clay was deposited. It is interesting to note that workers on the sediments of Crystal Lake, Wisconsin, found that the lowest diatomaceous layers contained species which may be identical with those of the lower deposits of Windermere. It is possible that the brown mud of Windermere may have been laid down during the period since the early Boreal, while the deposits associated with the clays may have accumulated during the period of ice recession.

Unfortunately, pollen is very scarce in the deposits, and no satisfactory time-correlation can yet be made. The only layers containing appreciable quantities of pollen are the peat bands which occasionally occur in the soft deposits of the narrow clay zone. In the lowest of these layers, the pollen is practically all Pinus, while several layers towards the top of this zone contain oak, birch, alder and hazel pollen. This would seem to indicate deposition in Boreal and Atlantic times respectively, but the sediments associated with the lower layers contain a diatom flora similar to that of the supposed late-glacial silts occurring in the laminated clay. In the present state of our ignorance of the ecological requirements of diatom species and considering the fragmentary nature of the pollen figures, it is not possible to date the deposits with any certainty. It is possible, however, that measurements of the varves in the laminated clay may indicate some correlation between these and the time-scale established by De Geer from the Swedish and other varves.

Mr. D. J. Scourfield has examined the cores for animal remains, which were fairly frequent in the muds but apparently absent in the clays. Rhizopod tests and Cladocera fragments were frequent at all levels, while parts of insects, particularly Chironomus, and remains of small mites were occasionally found. By far the most abundant remains were those of Bosmina while three other planktonic Cladocera, Daphnia, Bythotrephes and Leptodora, and a considerable number of littoral forms belonging to the family Chydoridæ, were present. The same species occurred in all the cores in the brown mud, in the organic layers between the narrow clays and in the organic silts within the laminated clay. Although the remains are not sufficient to allow quantitative estimates to be made, it is concluded that the Cladoceran population has shown little if any change since glacial times, as all but one or two of the species recorded are living in the lake to-day. The absence of Daphnia valves and headshields and copepod remains in the cores is striking in view of their dominance in the zooplankton at present. This may perhaps be due to differences in rates of decay.

The main conclusions of this research are as follows: a successful method for raising undisturbed cores from the bottom deposits of lakes has been developed. The examination of cores so far obtained confirms the value of the echo-sounding machine as a means of providing data on certain types of lake deposit, and discloses a part of the climatic and biological history of Windermere.

EXPLOSIVES*

By Prof. G. I. Finch, M.B.E., F.R.S.
Imperial College of Science and Technology

Nature of an Explosive

An explosive is a store of chemical energy in liquid or solid form which can be rapidly converted into heat and thence into mechanical energy. The explosive products must be gaseous, either wholly or in part, because the heat energy of solid or liquid products is not directly available for doing work by expansion. It is a popular fallacy that an explosive is an unusually rich store of energy. The fact is, however, that with sufficient air petrol is, weight for weight, capable of doing nearly eight times as much work as nitroglycerine, which is one of the most powerful of explosives; but nitroglycerine does its work much more swiftly, disrupting and pushing away its surroundings in a fraction of a second.

There are several ways in which chemical energy can be stored to form an explosive. For example, we can mix a combustible material like sugar with an oxygen-rich compound such as potassium chlorate. A far more perfect apposition of combustible and oxygen is secured, however, when both are suitably combined into a single chemical compound. But this combination is a peculiar one, in that the combustible and the oxygen are only loosely or indirectly associated in the molecule, usually through the intermediary of some relatively inert atom such as nitrogen, as, for example, in ammonium nitrate. This is, however, not the only way of storing up chemical energy to form an explosive compound. Any compound is a store of chemical energy if a rearrangement of its constituent atoms is possible which is attended by the evolution of heat; and if the rearrangement can occur swiftly with the formation of gaseous products, then the compound is an explosive. Thus the dissociation of acetylene into soot (solid carbon) and molecular hydrogen liberates heat, and acetylene has long been recognized as an explosive gas, particularly when compressed. We can, most conveniently, effect this compression chemically, that is, by making use of some of the chemical energy stored in acetylene. Thus the hydrogen of acetylene is easily replaced by metals such as copper, silver and mercury. The resulting compounds are solids, so that their chemical energy is concentrated into a far smaller volume than in acetylene gas itself. These acetylides are violent explosives, which decompose into soot and a highly heated gas of metallic atoms. In this case it is the resolution of the acetylene triple bond into the single bonds of soot which is the source of the heat energy.

There are other kinds of atomic arrangements which can serve as stores of easily released chemical energy. For example, although the dilute hydrogen peroxide of commerce is harmless, the pure liquid compound is explosive and decomposes readily into steam and molecular oxygen. Pure ozone, especially in the liquid or solid state, is an even more violent explosive. In each case the removal of an oxygen atom from the molecule requires the expenditure of much energy, but this is more than balanced by the heat evolved by the subsequent union of two such atoms to form a molecule of oxygen. Another atomic grouping where, on explosion, the main source of heat energy is furnished by the combination of like atoms to the molecular state is the triazo, $-\mathrm{N}{=}\mathrm{N}{\equiv}\mathrm{N}$, group. Hydrazoic acid, HN_3, is an explosive liquid which readily forms a series of explosive metallic salts, of which lead azide is much used in the explosives industry.

An example of a class of compound in which the heat energy liberated on explosion results partly from the union of a combustible with an oxygen atom and partly from the formation of a molecule from like atoms is furnished by the fulminates. These are metallic salts of fulminic acid, $\mathrm{H}{-}\mathrm{O}{-}\mathrm{N}{\equiv}\mathrm{C}$, of which the best known is mercury fulminate, $Hg(ONC)_2$. On explosion, an atomic rearrangement takes place to yield as sole explosion products carbon monoxide, molecular nitrogen and mercury.

Sensitiveness

The sensitiveness of an explosive reflects its stability, being a measure of the energy required to dislocate the arrangement of the atoms in its constituent molecules to such an extent that they tend to relapse into a more stable configuration rather than to return into their original positions. It is difficult, however, to obtain an absolute measure of this 'least initiating energy', as it may be called, and in practice comparative tests must suffice. The results are sometimes conflicting; thus, nitroglycerine is less sensitive to a hammer blow, but more sensitive to heat than lead azide. Recent advances in our knowledge of crystal and molecular structure and of the nature of the chemical bond, seem to offer a fair prospect of a better understanding of the energy relationships involved in initiating the explosive process, at least in those compounds which are crystalline and of simple molecular structure, like, for example, the acetylides and the azides.

---

* From a lecture at the Royal Institution delivered on February 11.

When an unconfined explosive is ignited by a flame, one is struck by the fact that, with certain few exceptions, explosives respond in one of two very different ways. Thus, match compositions, nitroglycerine, guncotton, blasting gelatine, cordite and gunpowder burn quietly, some more quickly than others, with flames of characteristic colour. Picric acid, trinitrotoluene and the aromatic nitrates in general burn sluggishly with a sooty flame. In striking contrast to this quiet burning is the behaviour of most of the acetylides, azides and the fulminates, which explode with great violence and set up intense shock waves when ignited. A closer examination reveals that this violent explosive process is preceded by a short period during which an initially slow rate of burning rapidly accelerates until the violently explosive stage is reached. In the case of burning, the energy needed to start decomposition in the hitherto unaffected portion of the explosive is handed on as heat from the burning zone to the adjacent unconsumed layer, which is thus ignited, and so on from layer to layer throughout the explosive. On the other hand, the succeeding violently explosive stage is due to the setting up, as the result of a rapidly accelerating rate of burning, of a steep-fronted sound wave which travels through the explosive at a high uniform speed. The intensity of this wave is so great, approaching 150,000 kgm./cm.^{2}, that the explosive at the wave front may momentarily be heated, by adiabatic compression, to a temperature of the order of 10,000° C., so that the resulting explosion is propagated hand-in-hand with, and maintains the intensity of, the shock wave in its passage throughout the explosive. In traversing an inert medium, such as air, this intensity of course decreases rapidly; nevertheless, the shock wave may still be capable of effecting explosion, even though attenuated by passage through a considerable air gap.

DETONANTS

The process whereby explosion is effected by a shock wave is known as detonation. An explosive which, even when unconfined, burns rapidly to detonation may be called a detonant. The shock wave is usually known as the detonation wave. Its velocity lies between 3,000 and 9,000 metres per second, and is related to that of sound in the same medium; hence, each explosive has its own characteristic and constant rate of detonation. The detonants, of which lead azide and mercury fulminate are the best known representatives, play a vital part in the use of modern high explosives.

Ability to burn to detonation is not necessarily associated with a high degree of sensitiveness, nor is it evidence of high energy contents of the explosive, as is sometimes supposed. For example, both nitroglycerine and cordite are roughly four times as powerful as mercury fulminate or lead azide. The explanation lies rather in the nature of the explosion products of such detonants, which are for the most part unable to dissociate appreciably, so that the chemical energy is transformed into heat in a single step instead of relatively slowly, by a succession of stages.

PROPELLANTS

The large class of explosives which burn quietly when unconfined may be further subdivided into propellants and the so-called high explosives, according to their behaviour when ignited by flame in a strong enclosure. A propellant, like gunpowder or cordite, merely burns. If it is non-porous and uniform in texture, like cordite, the propellant continues to burn from layer to layer at much the same uniform rate as when unenclosed, while a porous substance, like gunpowder or a partially gelatinized smokeless powder, burns at a less uniform rate because the accumulating pressure forces hot gases into the pores and thus increases the rate of burning. Under similar conditions a high explosive, after a more or less prolonged period of burning of somewhat uncertain duration, eventually detonates.

As the name implies, the function of a propellant is to propel a selected object in a desired direction. It is essential that the pressure of the explosion gases on the projectile should neither vary abruptly nor stress the gun unduly. At the same time the maximum permissible pressure should be continually exerted on the projectile and, to avoid waste, the charge must be completely consumed before the projectile arrives at the muzzle. These demands are met by a proper choice of the area-to-weight ratio of the propellant. For example, the cordite in a rifle cartridge consists of some fifty rods each about as thick as a darning needle. In a big gun, however, where the projectile takes much longer to arrive at the muzzle, the rods may exceed one inch in diameter.

An explosive which is liable to burn to detonation when confined as in a gun, is quite useless as a propellant. Should detonation occur, the gas pressure suddenly rises with such rapidity that the projectile cannot move fast enough to keep it within bounds, and the gun bursts and shatters into many fragments. Such disasters, or 'prematures' as they are sometimes called, were at one time by no means rare, and were due to the use of propellants of an unreliable nature. The possibility of a premature occurring with a modern high-class propellant like cordite is so remote as to be negligible. This does not imply that a propellant cannot be made to detonate like any high explosive, but rather that it will not do so under the conditions of its use in a gun.

High Explosives

In contrast to the propellants, the tasks which a high explosive has to perform are such as to require that its energy be made available in the shortest possible time. This can only be achieved by causing the explosive to detonate. If the gases were liberated slowly, as with a burning propellant, they would have time to open up weak places in the confining surroundings and then expand through these openings between the obstacles, instead of breaking up and flinging them away. For example, if the explosive charge in a shell were only to burn, then the slowly rising pressure would merely push out the fuse and the gases would escape through the fuse hole, leaving the shell intact. In the case of detonation, however, the gas pressure rises so quickly that there is no time for the inertia of the more easily removed obstacles to be overcome before the surroundings as a whole have been subjected to pressures which they cannot withstand. Hence when the shell-filling detonates, the shell walls are broken up into fragments which are pushed outwards with high velocity by the blast of the expanding gases of detonation. Similarly, a slab of guncotton, even though unenclosed and merely laid on a steel rail, will sever this on being detonated, but would leave it unharmed if the explosive were merely to burn.

When the manufacture of nitroglycerine had been established as a cheap commercial process, the problem of how to detonate it and thus unlock its energy to the best advantage became a pressing one. The solution was found in the discovery that the detonation wave in mercury fulminate, placed in contact with nitroglycerine, could set up in it a fresh detonation wave with a velocity characteristic of this medium.

Whilst the more sensitive high explosives, such as blasting gelatine and dry guncotton, can be detonated without fail in this manner, others, like moist guncotton and the aromatic nitro-compounds, especially when cast or highly compressed, are uncertain in their response to the effects of even relatively large amounts of detonant, being often merely broken up into fragments and scattered. The difficulty is overcome by interposing between the detonator and the main insensitive explosive a few grams of a high explosive which will respond with certainty to the action of the detonator, and then pass on its own detonation wave to the main body of the insensitive explosive. This intermediate explosive is generally known as the 'gaine.'

The choice of a high explosive is governed by the kind of work it will have to do, and by the treatment to which it is likely to be subjected before use. As shell fillings, only explosives which are highly insensitive to shock and friction can be used with safety; otherwise detonation may occur before the fuse acts, or even before the shell leaves the gun barrel. Also, the gaine explosive, and still more so the detonator contents, must be so packed and supported in the main body of the shell filling that they too can withstand with certainty the rough handling of being fired from the gun. Finally, when the filling does its work, the shell should break up into swiftly moving fragments of the most effective size, and not be merely split into a few large pieces or completely pulverized. If nearly all the chemical energy became available immediately on detonation, as is the case, for example, with lead azide, the shell would be broken up into powder and fragments too small for effective flight, and the explosive is said to be 'brisant' or shattering. On the other hand, if the chemical energy is transformed into heat by a succession of steps as, for example, where such easily dissociated molecules as steam and carbon dioxide form the bulk of the explosion products, the shell fragments are likely to be too large; an effect to which a low velocity of detonation may also indirectly contribute. Finally, in order that the fragments should move away with high velocity, or that the shell should do as much damage as possible on bursting after penetration into an obstacle, the explosive should have high chemical energy contents and yield only gaseous products. These requirements can best be met by mixing together two or more explosive compounds, a procedure which may have, among others, the advantage of enabling costs to be reduced. Amatol, a high explosive consisting of a mixture of trinitrotoluene and ammonium nitrate, was introduced as a shell filling during the War of 1914–18; it was cheap and proved remarkably successful.

The high explosives used for blasting in quarrying and mining can be sufficiently sensitive to respond to a detonator without the added complication of an intermediate gaine, because the treatment which they receive in the course of transport, handling, and in the final packing into the shothole, is mild compared with that which a shell filling has to withstand. Here again, the properties of the explosive must suit the work in hand. For example, in tunnelling through hard rock, a shattering and powerful explosive will serve best by breaking up the rock into small pieces easily handled for removal. On the other hand, for quarrying out large blocks of stone or in coal mining, where 'small stuff' represents waste, explosives are used which are comparatively slow in their action. Owing to the danger of coal dust and firedamp explosions, so called 'safety' explosives have been introduced for use in coal mining. These are slow-acting high explosives in which are incorporated substances like crystal soda which, by absorbing heat, prevent the temperature of the explosion flame from rising sufficiently to ignite coal-dust and methane-air mixtures.

OBITUARIES

Prof. William Bulloch, F.R.S.

PROF. WILLIAM BULLOCH, emeritus professor of bacteriology in the University of London, whose death occurred on February 11, was a bacteriologist of world repute and the historian of bacteriology. He took up the science of bacteriology in its early days and lived to see it reach its modern importance. In these early days there were but few masters, but he made it his aim either to study with them or make himself familiar with their ideas and technique, and with Koch, Salomonsen, Metchnikoff, Ehrlich and Roux he maintained an intimate friendship.

William Bulloch was born in Aberdeen in August 1868 and studied at the University there, taking his M.B., C.M. in 1890 and afterwards studying in several centres of learning on the Continent (Leipzig, Paris and Vienna). He was a brilliant student and was awarded many academic prizes and honours. Among the more important appointments which he held were that of assistant professor of pathology, University College, London, where he came into contact with David Ferrier and Victor Horsley; and bacteriologist at the Lister Institute, where he was associated with Lord Lister, of whom he became a life-long friend. In 1897 he was appointed bacteriologist to the London Hospital, to which he remained faithfully attached for the rest of his scientific career.

His great ability, his wide knowledge of his subject, and his integrity, soon established Bulloch as one of the foremost authorities on bacteriology in Great Britain, and for this reason he was invited to fulfil many important positions of trust. Thus he was chairman of the governors of the Lister Institute, an original member of the Medical Research Committee (Council), a member of the Government Committee on Foot and Mouth Disease, a member of the Committee of the Beit Memorial Trust, president of the Section of Pathology of the Royal Society of Medicine, honorary librarian to the Royal Society of Medicine for many years, and honorary fellow of this Society in 1940, honorary member of the Pathological Society of Great Britain and Ireland, etc. He also gave many important lectures in connexion with bacteriology.

Bulloch added much to the knowledge of his subject, and the more important of his published works covered such subjects as tuberculosis, bacteriological filters, studies in pathology, hæmophilia (with Fildes) in the "Treasury of Human Inheritance", the sterilization of catgut and diphtheria—its bacteriology, pathology and immunology, with others for the Medical Research Council.

I first met Bulloch some thirty-five years ago when a student. In the course of conversation I mentioned that I was about to go abroad to study, and he at once furnished me with the necessary introductions; the latter, as all friends of Bulloch know, acted as a magic charm to the portals of the great masters. Later, when I went to work in his Department at the London Hospital, I learned much of the man and his ideals. Bulloch was extremely conservative; in his own mind only the written word was authoritative, and us younger men he regarded somewhat as Bolsheviks in our views and methods. Thus some new procedure of technique we had devised or adopted would call forth the remark, "such methods are enough to make Pasteur and Koch turn in their graves". Yet in spite of this expression of doubt as to the success or usefulness of our investigations he would, a morning or two later when he came in for a friendly chat, present us with the latest literature on the subject of our research. The same interest in our progress was continued even when we had passed on from his Department. This generous disposal to us of his wide and accurate knowledge was in strong contradiction to his lack of interest in teaching medical students, which to him was of the nature of a necessary evil.

Perhaps Bulloch's outstanding characteristic was his highly developed critical faculty, at times devastating and even a little cruel when directed against imperfect or inaccurate work, only equalled by his intolerance of intrigue and advertisement. In his earlier days woe betide those who failed to come up to his standard, either in their writings or at a scientific meeting. But those who worked for him, even though his criticism was sometimes irritating, learned much that was to prove the foundation of their later successes.

Though brusque in manner, at home Bulloch was a genial and kindly host and liked to give play to his favourite hobby, the study of the frailties of the great men of his subject and of his immediate and humble associates. This gave him a fund of very amusing stories which he loved to recount with a clever mimicry, worthy of Coquelin himself, as a

French man of science once remarked. For this reason afternoon tea in the laboratory was a feast of wit and humour not to be missed. Strange to say, in spite of his cynicism, he was definitely a hero worshipper, and they were many and varied.

Bulloch had a prodigious memory and could give accurate references as to where and when most of the important papers on bacteriology had appeared. He had undoubtedly great influence in raising the standard of bacteriology in Great Britain to its present high level. Though his later years were clouded by long illness, he carried on to the very end his intense interest in all that pertained to bacteriology. Even the London 'Blitz' and the obliteration of the houses next door could not daunt him, as a recent letter I received from him, in the familiar purple ink, showed. We who had the privilege of working under him will long remember his ideals, his wit and his cheerfulness, and bear in our minds the picture of that short sturdy figure, with his carefully polished shoes, pipe in mouth, disappearing down the stairs after tea to commence in the library his real interests of the day.

J. McIntosh.

Dr. C. B. Ticehurst

By the death of Dr. Claud Buchanan Ticehurst of Saxon House, Appledore, Kent, on February 17, in a nursing home at Hastings, the science of ornithology in general and the British Ornithologists' Union in particular have suffered a loss which it would be difficult to exaggerate. It will be still more difficult to fill the gap which his death will cause in the publication of the Union's journal—the *Ibis*—of which he had been the successful and zealous editor since 1931. From his youth Ticehurst was what we might call a born field-ornithologist, but it was at Cambridge, where he was an undergraduate studying medicine at St. John's College, that ornithology came to be the leading passion of his life under the happy guidance and encouragement of Prof. Alfred Newton, whose Sunday evening gatherings were an inspiration and a joy to so many, including such famous ornithologists of the old days as Canon Tristram, the Godmans, Sclater, Wolley, Lilford, Gurney, Salvin, Taylor, Eyton, Wollaston and many others. Ticehurst was one of the many young men of those days who received, so to speak, the accolade; and had it not been for the strenuous calls on a country practitioner's time there can be little doubt that he would have risen to the highest level of ornithological fame.

As it was he established an international reputation, and not only found time to conduct the editorial business of the *Ibis*, only possible by constantly sitting up until the early hours of the morning, but also by clever manipulation of his scanty holidays found it possible to visit such countries as Norway, Portugal, Spain, the Balearic Islands, Holland, France, Yugoslavia, Albania, Egypt and Algeria; to say nothing of the important work he did in India when serving in the R.A.M.C. in the War of 1914–18. In all these countries he made collections of birds with the object of studying plumage changes, geographical distribution and migration. He also published papers in various scientific journals on the birds of Mesopotamia, Sind and Burma; was the author of one of the best county avifaunas—"The Birds of Suffolk"—and proved his sterling merit by writing a monograph on the willow-warblers (Phylloscopi) for the British Museum.

His untimely and much deplored death at the early age of sixty interrupted the work which he was carrying out in conjunction with Mr. Hugh Whistler on the birds of India, Burma and Ceylon.

Following in his father's footsteps, Ticehurst was a very skilful dry-fly fisherman; and by his death, if I may introduce a personal note, I lose a beloved and cheery companion by the banks of the Test. He was never so happy as when tempting (and quite successfully) the rather sophisticated inhabitants of that famous chalk stream (and the Kennet) with his father's self-tied flies, many years old as they were. Some of them had seen such long and faithful service that I think I must have known them by sight.

Percy R. Lowe.

We regret to announce the following deaths:

Prof. F. M. Andrews, professor of botany in Indiana University, on November 26, aged seventy.

Dr. James Balfour, F.B.A., the well-known economist, on January 18, aged eighty-eight.

Mr. M. R. Campbell, formerly principal geologist of the U.S. Geological Survey, on December 7, aged eighty-two.

Sir Charles Fielding, K.B.E., director-general of food production during 1918–19, on April 9, aged seventy-seven.

Prof. W. W. Ford, emeritus professor of bacteriology in the Johns Hopkins University, on February 10, aged sixty-nine.

Prof. W. C. Graustein, professor of mathematics in Harvard University, on January 22.

Prof. J. E. Guberlet, professor and member of the staff of the Oceanographic Laboratories of the University of Washington, aged fifty-four.

Mr. S. Henshaw, emeritus director of the Harvard Museum of Comparative Anatomy, on February 5, aged eighty-nine.

Prof. F. C. Jordan, professor of astronomy and director of the Allegheny Observatory, Pittsburgh, on February 15, aged seventy-five.

Dr. G. W. C. Kaye, O.B.E., F.R.S., superintendent of the Physics Department, National Physical Laboratory, on April 16, aged sixty-one.

The Right Hon. Lord Stamp, G.C.B., G.B.E., F.B.A., aged sixty, and Lady Stamp and the Hon. Wilfred Stamp, during a recent air raid.

Dr. J. P. Sutherland, emeritus dean of the Boston University Medical School, on January 24, aged seventy-four.

NEWS AND VIEWS

Agricultural Research Council: Sir Edwin Butler, C.M.G., C.I.E., F.R.S.

CHARGED as it was with the scientific supervision of the widespread organization for agricultural research which has been developed in Great Britain since 1911 and holding (as many may think unfortunately) but few of the purse strings directly, the policy of the Agricultural Research Council has been to guide and stimulate work in progress at research institutions, rather than to attempt control. As the late Sir William Hardy expressed it, "free" not "directed" research was what it desired to promote. In giving effect to this policy, Sir Edwin Butler proved himself an ideal secretary. An acknowledged leader in his own subject, mycology, he had, as director of institutions in India and Great Britain, gained a wide knowledge of the problems and the methods of the agricultural investigator. He quickly made himself familiar with the work of the research institutes and he visited them frequently. Nor was he ever an unwelcome visitor, since directors and members of staff alike soon found that in him they had a real friend, always ready to interest himself in their problems, always ready with helpful suggestions. To the Council the contacts thus established were invaluable, as were also his detailed descriptive reports. His conclusions could be accepted with confidence; they were marked by proofs of full understanding, careful weighing of evidence and absolute fairness. His personal qualities made him the best of colleagues and it was with great regret that, because of the verdict of his medical advisers, his resignation from the secretaryship was accepted. But this did not come until he had left behind him a permanent memorial of his tenure of office.

When, in 1935, Sir Edwin became its secretary, the Council was searching for a suitable estate on which to establish a field station for experimental work on farm animals; a number of estates was visited and when Compton was seen, Sir Edwin was the first to recognize its possibilities. After it had been acquired its development owed much to him, in particular the fine range of laboratories, and the homes for laboratory animals are largely the result of the care which he, in consultation with Mr. Dunkin, the director, bestowed on the planning of details. Members of Council and others who visit Compton in future must always associate these buildings with the name of Sir Edwin Butler, who watched over their construction from foundation to completion with unceasing care.

Prof. W. W. C. Topley, F.R.S.

PROF. W. W. C. TOPLEY, who now becomes secretary of the Agricultural Research Council, like his predecessor, holds a medical qualification, and like him decided to work for the advancement of science, rather than follow a professional career; but whereas Sir Edwin chose plant pathology as his special subject, it was on science as affecting animal health that Prof. Topley specialized. His name until now has been so closely associated with bacteriology in relation to human medicine that surprise may be felt by some to find him among the agriculturists. But he does not come among them as a stranger. Since the earliest days of the Agricultural Research Council, Prof. Topley has been a valued member of some of its committees on animal health. In 1939 he became a member of Council and he is chairman of the committee in charge of the particular investigation for which the Compton Field Station was, in the first instance, acquired.

It was with great pleasure that his colleagues learned recently that Prof. W. W. C. Topley was willing to accept the post vacated by Sir Edwin and that his qualities of initiative, drive, clear thinking and direct, convincing manner of speech when advocating a cause in which he believes have now been secured for agriculture. In the uncertain days which lie ahead, it is a comforting thought for all who have the progress of agricultural research at heart to know that as its Secretary the Council has secured the services of a man who has not only made outstanding contributions to science, but has also proved himself to be an inspiring leader of others. It may be that those primarily interested in medicine may regret Prof. Topley's decision, but let them not forget that in recent years it has become increasingly clear that the foundations of human health are deeply laid, that man's physical well-being depends in no small degree on the health of domestic animals, on the properties of cultivated plants, and ultimately indeed on the special characteristics of the soil itself. Medical science will not lose, but gain, by Prof. Topley's transference to the wider field of agricultural science.

Centenary of the Pharmaceutical Society

IN the afternoon of April 15 several hundreds of pharmacists attended a meeting at Conway Hall, Red Lion Square, London, which was held to celebrate the centenary of the Pharmaceutical Society. Mr. Walter Deacon, who presided, introduced Sir John Anderson, Lord President of the Council who, he said, now had many dealings with representatives of the Society at the Home Office and elsewhere. In his address, Sir John said it was fitting that someone with a knowledge of the circumstances of pharmacy extending over thirty years should attend the meeting as a representative of His Majesty's Government to pay tribute to the Society's past achievements and to wish it well for the future. The founders of the Society, he continued, laid down that its main purpose should be to advance chemistry and pharmacy, and the constancy with which their successors had pursued that aim deserved the fullest recognition. Modern developments of medicine have changed completely the work of the pharmacist, and it is right that the public should now know how successful have been the efforts of the Pharmaceutical Society to keep in line with the advance in knowledge and the great progress of medical science. A play, "Jacob Bell and Some Others", specially written for the occasion by Mr. H. N. Linstead, secretary of the Pharmaceutical Society, and produced by Donald Wolfit, followed the speeches. It brought vividly to the large audience episodes associated with the Society's foundation.

Haricot Beans

At the request of the Ministry of Agriculture the Imperial Bureau of Horticulture and Plantation Crops, East Malling, has issued a bulletin compiled by G. St. Clair Feilden, on haricot beans (Occasional Paper No. 6. 1*s*.). Hitherto cheap supplies of beans from North America, Japan and Hungary have discouraged farmers in the United Kingdom from embarking on a crop that proves only fully successful in a dry summer. In war-time, however, it seemed advisable to re-examine the possibility of providing such a valuable addition to the nation's food, and yields of one ton or more per acre were obtained in trials made in 1940. The bulletin contains a brief account of work with haricots in the United States and Canada and of the results of experiments in England at various centres. Cultivation is outlined and harvesting and cooking methods are described. The varieties at present available, though they did well in England in 1940, are really more suited to warmer and drier climates, and it is to be hoped that some growers will become sufficiently interested to hybridize and select strains that are more dependable to ripen a full crop in Great Britain.

War Fellings and Insect Pests

In the *Scottish Forestry Journal* (54, Pt. 2, Oct. 1940), Dr. A. E. Cameron, of the Department of Entomology, University of Edinburgh, writes on "The Effect of Felling on the Incidence of Forest Insect Pests". The many fellings throughout Britain during the War of 1914–18 and the remnants left on the ground for several years thereafter were the breeding places of large numbers of some of the more dangerous of our insect pests, which afterwards spread destruction in young, middle-aged, and old woods throughout the country. Once again we are faced with a similar emergency, and the same aftermath of the fellings is to be seen on many a site of a former wood, now felled for war purposes. The insect pest question, as Dr. Cameron says, is likely to be acute in the near future unless attention is given to it, and some effort made to counter its possible or certain virulence. The author practically confines himself to conifers and their chief pests. But in parts of Great Britain there is an equal danger to some of the valuable hardwoods, including oak, ash and elm, to mention three only. But since the major part of the afforestation work of the Forestry Commission is connected with the conifers, the question of this possible insect danger is greater now than it was in 1918, when there was a comparatively small area of young conifer plantations in the country.

Dr. Cameron deals with the different types of forest and their respective immunity or otherwise. He says that our only indigenous conifer, the Scots pine, is the most-subject to attack by several species, but that the other conifers, exotics, such as spruce, Douglas fir and larch are subject. The chief dangerous pests are the weevils, *Hylobius abietis*, *Pissodes notatus* and *P. pini*, and the pine beetles, *Myelophilis piniperda* and *M. minor*, *Hylastes ater* and *Pityogenes bidentatus*. In order to combat these pests, Dr. Cameron states that their habits must be known intimately, and then some measures of control which he details may be instituted.

Anthropological Observations in New Guinea

Information relating to the work of an expedition of anthropological, ethnographical and linguistic investigation in the little-known north-eastern region of New Guinea under the leadership of Dr. Georg Höltker is given by Dr. Otto Schlaginhaufen in the current issue of the bulletin of the Swiss Anthropological and Ethnographical Society (*Bull. Schw. Gesell. f. Anthrop. u. Ethnol.*, 16, 1940). The expedition, which had recently returned at the time of writing, was in the field for the three years 1936–39. Its operations covered the coastal region south-eastwards from the mouth of the Sepik River, and the coastal and inland territory on the east side of the lower waters of the Ramu River, and country in the basin of the Mbur, a tributary of the Ramu, as well as islands of the coast including Manam and Dampier. Of the peoples under investigation by the expedition a proportion were classifiable linguistically as belonging to the Melanesian stock, but the greater number were Papuan. Anthropological observations were made by Dr. Höltker on members of the former group on the mainland—Sepa and Wanami living to the south of the coastal peoples of Monumbo (Potsdamhaven) and on the islands. The Papuan group examined included the Bosgung on the Mbur, Watum to the south of the Sepik and among inland peoples, Tanggum, Ariaw, Mikarew, Dinam and Akekom. Observations were made on 1,685 individuals, both adults and children.

Earthquake in Mexico

A severe earthquake shook more than 20,000 square miles of territory in northern Mexico on April 15, causing much damage to property, and, it is feared, a heavy death roll. Full details are as yet lacking, but preliminary facts may be given. The States most affected were Aguascalientes, Colima, Guanajuato, Jalisco, Mexico, Michoacan, Puebla and Tlaxcala, the isoseismals apparently being elongated in an east-west direction. The epicentre may have been in the neighbourhood of Chilpancingo, though very great damage was done to the city of Colima, capital of the State of Colima, 275 miles west of Mexico City. In Colima the homes of approximately 10,000 people have been reported destroyed. There were damage and loss of life also at other towns, including Guadalajara and Manzanillo, and as far east as Maltrata in the State of Vera Cruz. Mexico

City was only slightly affected. At the same time, the volcano near Colima erupted, setting fire to forests. These fires further threatened Colima.

Recent Earthquakes recorded at Kew

FOUR large earthquakes have been recorded at Kew in the period March 23 – April 13. The first was received at 22h. 41m. 17s. G.M.T. on March 28 and may have been from an epicentre 19,000 km. distant, though the initial movements were confused by microseisms. The second was at 10h. 52m. 19s. on April 1, probably from an epicentre 7,870 km. distant, while the third, at 15h. 34m. 31s. G.M.T. on April 3, had its epicentre 9,180 km. away. This latter had a particularly prominent wave on all three components at 15h. 33·5m. G.M.T., which may have been *eSSS*. An earthquake giving a full suite of pulses had *iP* dilatational at 23h. 40m. 27s. G.M.T. on April 7 and did not cease recording until 3h. 20m. G.M.T. on April 8. It probably had its epicentre 7,920 km. distant from Kew, though all calculated epicentral distances are tentative.

Canadian Polar Year Expeditions

THE first volume of a work which describes the observations carried out by the Canadian Polar Year Expeditions, 1932–33, is largely statistical; but there is a general introduction by Dr. J. Patterson, the director of the Canadian Meteorological Service, and notes on the instruments at the Expeditions' four stations—Cape Hope's Advance, Chesterfield Inlet, Coppermine and Meanook, together with maps and photographs (Dominion of Canada: Department of Transport, Air Services Branch, Division of Meteorological Services of Canada. Canadian Polar Year Expeditions, 1932–33, Meteorology: Cape Hope's Advance, Chesterfield Inlet, Coppermine, Meanook. Vol. 1. Pp. xvi + 443 + 46 plates. Ottawa: King's Printer, 1940). Meanook (Alberta) is a permanent magnetic station—the nearest to the north magnetic pole—the other three stations were temporarily set up for this undertaking. The statistical matter which, as has already been mentioned, occupies a very large proportion of the volume, consists mainly of hourly values of atmospheric pressure, temperature, humidity, precipitation, sunshine and wind velocity, to which are added full particulars of the upper winds revealed by numerous observations with pilot balloons, and notes on optical phenomena. The period covered—August 1932–September 1933—is long enough to illustrate the inhospitable climate of these regions, with frequent gales and strong winds, and a long and severe winter. The complete absence of trees, and even of bushes, worthy of the name, at the more northerly stations needs no other explanation.

At Coppermine, pilot balloon observations were supplemented by seventy-four soundings with kites carrying Marvin meteorographs lent by the U.S. Weather Bureau, but the results do not appear to be given in this volume. The same station was supplied with several Patterson flashing-lamp balloon meteorographs. This is a very light form of meteorograph which indicates pressure and temperature by the lighting up of a string of electric bulbs suspended by a silk cord beneath the balloon, an observation consisting of the identification of the bulbs shining at a particular moment. Graphs of temperature observations up to 2 km. obtained in this way in March 1933 are given, all of which show at least one inversion or disappearance of lapse of temperature with height, below 1 km. At Meanook, the most southerly of the four stations (54° 37′ N.), noctilucent clouds of the kind described by Størmer were observed on the night of July 20–21, 1933, at a height exceeding 55 km. This appears to be the first occasion on which such clouds have been noted in America.

A Plastic for Thermal Insulation

IN the electrical industry cellulose acetate is widely used in both sheet form and as mouldings. A multilayer insulating material, made from cellulose acetate, and known as 'Isoflex', is described in the *Electrician* of March 7. Isoflex is manufactured from cellulose acetate film and in structure is not unlike corrugated cardboard used for packing purposes, with about five layers to each inch of thickness. It has a thermal conductivity of 0·32 B.TH.U. per hour per sq. ft. per in. thickness per 1° F. difference of temperature, so that its insulation properties compare very favourably with slab-cork (0·25 B.TH.U.), glass-fibre (0·28 B.TH.U.) and wood fibre board (0·38 B.TH.U.). Its volume weight of 0·75 lb. per cu. ft. works out at about one-tenth that of slab-cork. This makes it of considerable interest in connexion with thermal insulation during transport.

Isoflex is non-porous and non-absorbent, with the result that its thermal insulation is not impaired by the deposition of moisture in the material. Its construction in the tubular form allows free draining of condensed moisture. From the constructional point of view it is very easy to handle, as it can readily be cut by a knife. It will withstand wear and tear, and it does not disintegrate under the severe vibration of a railway coach; it is inert to salt water, thus making it suitable for marine work. It will not ignite or burn by itself, and therefore its installation does not result in an increase in the fire risk. However, it melts at about 175° C. and it is not suitable for heat insulation at temperatures which exceed 75° C. Isoflex is available in two types of slab. One type, known as the standard slab, is 24 in. square and is rigid; the other, the flexible slab, measures 23 in. × 20 in. By cutting one or other of these slabs, and by using a combination of them, any desired shape can be built up without difficulty.

Electric Supply in Churches

THE eighth report of the Central Council for the Care of Churches includes a timely memorandum for the guidance of parochial authorities about to install new lighting apparatus, and a series of regulations to be observed by contractors. In a preface to the regulations is a statement that the work must comply with the regulations of the Institution of

Electrical Engineers. Cables must be rubber- or paper-insulated and must be run in heavy-gauge solid-drawn galvanized-welded screw conduit (preferably) or in heavy-gauge welded screw conduit. Alternatively, 'Pyrotenax' may be employed. Attention is directed to a modification of an electric soldering iron for heating sealing compound, which enables joints to be made on the spot instead of entailing removals to a bench for heating with a blow lamp, in order to avoid risk of fire where timber is adjacent.

Cables of the supply undertaking should be taken into the building for as short a distance as possible and run only on brick or stone walls. Distribution boxes and fuses must be in cast iron cases. Instrument panels should be well clear of walls and should be of slate or other non-inflammable material; if of wood, only teak may be used. The wiring of ancient brass candelabra is condemned, as it would be almost impossible to remove the detachable brasses for cleaning. Electroliers or fittings must be hung on chains and their weight must not be borne by electric cables or flexible cords. All reachable metal work is to be earthed. Any relay or other circuit carried to a switch at an organ keyboard for starting a blower must be run in screwed conduit or be of 'Pyrotenax'; the starting switch must be in a metal case mechanically and electrically continuous with the circuit and with the approved earth connexion.

American Philosophical Society Publications

The American Philosophical Society has issued a list of books and papers in the Society's publications from 1769 until 1940 classified according to subject. This covers the papers, monographs, treatises and books, classified according to subject, and includes a subject index as well as a classified list, an author index and a price list. The *Transactions* of the Society is the oldest scientific journal with a continuous history in the United States, commencing in 1769; the six volumes issued in small quarto format up to 1809 are known as the "old series" and are out of print except for a few numbers. A new series was started in the present large quarto format in 1818, and to date thirty-one volumes have been issued.

The *Proceedings*, commenced in 1938, contain the original papers read before the Society as well as others accepted for publication. In view of the interest and value of some of the early material to the research student and historian, certain abstracts of papers read before the Society, verbal communications, letters on scientific and learned subjects, etc., included in the early *Proceedings* have been reproduced in the list. The *Memoirs*, commenced in 1935, consist of monographs and books each constituting a separate volume of the series, of which fifteen volumes have now been issued. In addition to its serial publications, the American Philosophical Society has published or sponsored for publication a number of separate works which are listed under "Miscellaneous Publications". Its library also maintains a photo-duplication service for supplying 35-mm. microfilm copies of out-of-print articles and manuscript material. Printed books are copied at the rate of 3 cents per standard frame, usually 2 pages per exposure. Manuscript is copied at the rate of 4 cents, usually 1 page, per exposure.

The Night Sky in May

The duration of night (sunset to sunrise) decreases from 9·3 hours on May 1 to 7·7 hours on June 1 in the latitude of London. Full moon is on May 11 and new moon on May 26. No bright star is occulted by the moon during the month. There is a general absence of bright planets in the night sky of this month. Jupiter and Saturn are now too near the sun for observation. Towards the end of May, however, conditions are favourable for seeing Mercury in the low western sky after sunset. In mid-May, Mars is nearly 5° above the eastern horizon soon after 3h. 30m. U.T., but sunrise is shortly after 4h. (add 2 hours to convert to new Summer Time). About this date the following constellations are near the southern meridian at dusk: Ursa Major, Canes Venatici, Coma Berenices, Bootes, Leo, Virgo, Crater, Corvus and Hydra. Pleasing in its symmetry is the formation of seven stars of medium brightness in Corona Borealis. A nova appearing near ε Coronæ Borealis in 1866 added to the lustre of this 'crown'.

University of Birmingham: Air Raid Damage

In a recent air raid, many bombs fell in the grounds of the University of Birmingham, and the chemistry buildings were hit. Fortunately, very little damage was done.

Civil List Pensions

A list of the pensions granted during the year ended March 31, 1941, and payable under the Civil List Act, 1937, has recently been issued. Among them are the following: *New Pensions:* Mrs. Mary Browne (services of her husband, the late Dr. Charles Browne, to anthropology), £100; Dr. C. C. Hurst (discoveries in science of genetics and their application to agriculture, horticulture and sociology), £130; Sir Alfred Matthews (services to agriculture), £150; *Supplementary Pensions:* Mrs. Jessie Bennett (services of her husband, the late Mr. Arthur Bennett, to botanical science: additional to £60), £40; Miss Fanny Bryant (services of her father, the late Mr. Thomas Bryant, to surgery: additional to £30), £70; Mrs. Barbara Kaye (services of her husband, the late Mr. Walter J. Kaye, to archæology: additional to £60), £40; Mrs. Johanna Miller (services of her husband, the late Dr. N. H. J. Miller, to agricultural science: additional to £50), £50; Miss Eleanor S. Sowerby (botanical works of her father, the late Mr. J. E. Sowerby: additional to £50), £50; Mrs. Elsie V. Sullivan (services of her husband, the late Mr. J. W. N. Sullivan, to literature: additional to £75), £25; Miss Helen S. Tichborne (scientific discoveries of her father, the late Prof. Tichborne, in chemistry and pharmacology: additional to £60), £40; Mrs. Ada E. Scott (services of her husband, the late Mr. Andrew Scott, to zoological science: additional to £80), £30.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Ionization Maximum for Protons

IN a recent paper, Holloway and Moore[1] have given a curve showing the average specific ionization, as a function of the residual range, for protons in air. On this curve the ionization maximum occurs at 1·9 mm. residual/range, and in the course of the paper the absolute value of the maximum specific ionization is quoted as 2,320 ion pairs per mm. The shape of the ionization/range curve was deduced from earlier measurements of Parkinson, Herb, Bellamy and Hudson[2], and the absolute value of the ionization was obtained on the assumption that, in the region of 3 cm. residual range, the mean specific ionization produced by a proton is a quarter of that produced by an α-particle of the same velocity. On this basis Holloway and Moore inferred that the maximum specific ionization is about one third as great for protons as for α-particles in air (6,760 ion pairs per mm.). Now, while there is overwhelming evidence for the correctness of this last assumption (the 1 : 4 ratio of ionizations for particles of the same velocity, when the ratio of the effective charges is constant at 1 : 2), it also appears that the conclusions, regarding the position and height of the ionization maximum for protons, to which the subsequent argument leads, run contrary to accepted evidence from other experiments. If this be admitted, then one must clearly assume that the results of Parkinson, Herb, Bellamy and Hudson will not bear the detailed analysis which Holloway and Moore place upon them, when protons of the smallest energy are concerned. It is the object of the present note to point out the contrary evidence referred to above.

As regards the position of the ionization maximum, the situation is relatively simple: this has been determined by Bower[3] from observations of the light scattered by cloud tracks of protons in a mixture of helium and air. Bower found a maximum in the scattered-light/distance curve at a point corresponding to 0·8 mm. residual range in standard air. While the method is quite different, and the definition of the end of the range not necessarily the same as in ionization chamber experiments, the discrepancy (0·8 as against 1·9 mm.) is greater than can be explained by such considerations. It can only be resolved by assuming that the velocity at which electron capture by protons becomes appreciable is much less in helium than in air. On the other hand, if we are to accept an increase in the assumed value of the maximum ionization (*v. inf.*), then the suggestion of a lower effective charge over the last few millimetres of residual range in air is clearly unwarrantable.

There are two distinct lines of evidence concerning the absolute value of the maximum specific ionization by protons which Holloway and Moore do not mention in the paper under discussion. In the first place, the experiments of Parkinson, Herb, Bellamy and Hudson provide some information which has still to be considered. In the α-particle case Holloway and Moore deduce the energy/range relation, for small values of the residual range, by integrating the differential specific ionization curve of Holloway and Livingston[4] and assuming a constant value for the average expenditure of energy per ion pair, for α-particles of all ranges. With protons, however, they deduce the shape of the differential ionization curve from the results of Parkinson *et al.*, while these results, in themselves, are believed to express the energy/range relation down to the smallest energies. Normalizing the differential curve against the corresponding curve for α-particles, as already described, Holloway and Moore obviously assume the same energy loss per ion pair for the two particles at high energies, yet for low energies a comparison of their differential-ionization/range and energy/range curves shows an apparent rapid increase of this mean energy loss for protons, as against the assumed constancy of this quantity for α-particles. Over the last 2–3 mm. of path, the energy/range relation gives an average rate of loss of energy almost exactly 10^5 ev. per mm. for protons in air (see Bethe[5]); if the differential ionization curve of Holloway and Moore were correct in this region, an expenditure of about 53 ev. per ion pair would be required. To set against this conclusion, for protons of about 8 mm. air range, a direct determination by Stetter and Jentschke[6] gave 32·6 ± 1·6 ev. per ion pair (in deuterium), compared with the accepted value of 33 ev. for α-particles of some cm. range.

The second line of evidence for a higher ionization maximum for protons derives from experiments on the photo-protons produced in deuterium by the γ-rays of thorium C''. Rogers (F. T.) and Rogers (M. M.)[7] have determined the mean energy of these protons as $(2{\cdot}25 \pm 0{\cdot}15) \times 10^5$ ev. from experiments with a cloud chamber in a strong magnetic field. Direct determinations of the mean number of pairs of ions produced by the photo-protons in deuterium have been made by Chadwick and Goldhaber[8] (7,200 ± 1,000) and, more accurately, by Stetter and Jentschke[6] (6,650 ± 200). From the measurements of Chadwick, Feather and Bretscher[9], Bethe[5] has calculated the mean air range as 2·28 mm. From these figures, again, the average expenditure of energy per ion pair in deuterium is 33·8 ± 2·6 ev., the same as for high-energy α-particles, and, if one takes this value for protons in air also (for high-energy α-particles the energy loss per ion pair is almost exactly the same in air as in hydrogen) then the mean ionization per mm. due to protons in air (over the last 2·28 mm. of path) is 2,900 ± 230 pairs of ions. If this be accepted, the maximum specific ionization cannot well be less than 3,400 ion pairs per mm.—or one half, rather than one third, of the maximum specific ionization due to an α-particle.

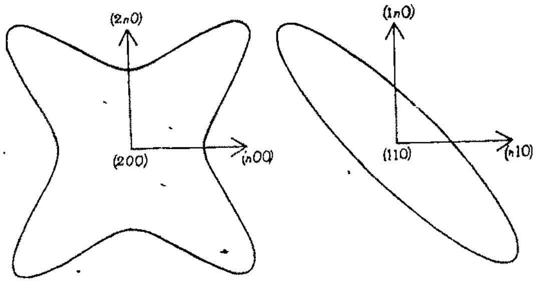
Diffuse Reflexion of X-Rays

IN a recent note Preston[1] has commented upon the agreement of his experimental results for the diffuse scattering of X-rays by single crystals of aluminium with the predictions of both the Preston–Bragg block hypothesis and a formula derived by Faxén. It seems necessary to correct the impression which might thereby be formed that the Preston–Bragg hypothesis is reconcilable with the Faxén–Waller theory. This is indeed not the case. It has been shown by Laue[2] that if the intensity of scattering from a finite crystal is plotted in the reciprocal lattice space as a function of the end-point of the vector $\vec{S} = \frac{\vec{\varepsilon} - \vec{\varepsilon}_0}{\lambda}$ (ε_0, ε unit vectors in the direction of incident and reflected ray, λ wave-length) drawn from the origin of the reciprocal lattice, then the resulting distribution of scattering power is periodic with the periods of the reciprocal lattice, so that in particular there is the same distribution about every reciprocal lattice point. On the other hand, the Faxén formula discussed by Preston is obtained by specialization (see below) from a general expression derived by both Faxén[3] and Waller[4] for the first approximation to the coherent diffuse scattering from a monatomic cubical crystal. This general expression can be written in the form:

$$I \sim \frac{(\vec{S}, \vec{A}_1)^2}{\nu_1{}^2} + \frac{(\vec{S}, \vec{A}_2)^2}{\nu_2{}^2} + \frac{(\vec{S}, \vec{A}_3)^2}{\nu_3{}^2},$$

where $\vec{A}_1$, $\vec{A}_2$, $\vec{A}_3$ are unit (and orthogonal) vectors defining the directions of oscillation of those three acoustical vibrations the wave vector $\vec{w}$ of which satisfies the Faxén-Waller vector condition (namely, $\vec{w} = \vec{S} - \vec{B}$, where $\vec{B}$ is that reciprocal lattice vector the end-point of which lies nearest to that of $\vec{S}$) and ν_1, ν_2, ν_3 are the respective frequencies of these vibrations. Owing to the occurrence in this expression of the cosines of the angles between the vector $\vec{S}$ and the vectors of oscillation, it is clear that the expression must lead to a different distribution of scattering power about each point of the reciprocal lattice. In a paper which I have in preparation, the general Faxén–Waller expression has been evaluated for various relative values of the three elastic constants c_{11}, c_{12}, c_{44} of a cubic crystal, and the marked dependence of the scattering power upon the elastic anisotropy demonstrated. For example, for sodium single crystals, using the values of the elastic constants determined by Quimby and Siegel[5], namely, $c_1 = 0{\cdot}760\ c_{11}$, $c_{44} = 0{\cdot}914\ c_{11}$ (at 200° K.), with cubic anisotropy $c_{11} - c_{12} - 2c_{44} = -1{\cdot}59\ c_{11}$, the section of the contours of isodiffusion of the 200 and 110 reflexions in the 200,020 plane of the reciprocal lattice approach, in the limiting case of long elastic waves, that is, proximity to the Bragg spot, the shape shown in the accompanying diagram.



THEORETICAL CURVES OF ISODIFFUSION FOR SODIUM SINGLE CRYSTALS.

Experiments to test the existence of these different distributions about different Bragg spots are being carried out in this Laboratory, although it should be pointed out that the earlier work of Laval[6] gives clear indication that these differences do exist in the manner required by the Faxén–Waller theory.

The special assumptions made by Faxén in arriving at the simple formula discussed by Preston included that of spherical isotropy for the elastic properties of the cubical crystal, namely, the relation $c_{11} - c_{12} = 2c_{44}$, which condition is fairly closely satisfied by aluminium ($c_{12} = 0{\cdot}57\ c_{11}$, $c_{44} \doteq 0{\cdot}26\ c_{11}$, $c_{11} - c_{12} - 2c_{44} = -0{\cdot}09\ c_{11}$); consequently the differences here will be less marked and more difficult to determine.

It should be stressed that we have in the diffuse scattering phenomenon a much finer method of exploring the vibrational spectrum of a crystal than is possible by studying, for example, the specific heat or the Debye–Waller factor; for whereas there one is dealing with averages over all directions of propagation of the elastic waves, here, in the diffuse scattering for a given crystal setting and direction of scattering, only those vibrations the wave-lengths and directions of propagation of which lie within restricted limits contribute to the scattering (Faxén–Waller vector condition).

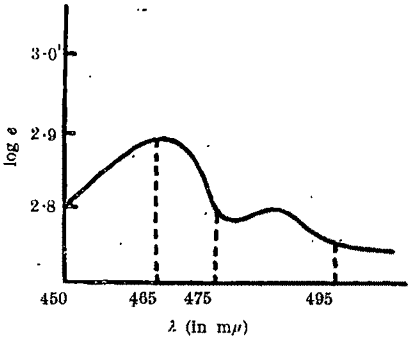
Formation of Ions from Compounds with Conjugated Double Bonds: Hydrocarbon Salts

IT has been suggested previously[1] that any system containing conjugated double bonds should be capable of forming ions, particularly positive ions. This holds not only in the case of carbon-carbon bonds (aliphatic or aromatic) but also in systems containing, for example, nitrogen, oxygen, sulphur, which, like carbon, can supply mobile π-electrons (double-bond electrons) which are essential for the 'metallic' behaviour of these compounds. Particular interest is attached to the hydrocarbons with conjugated rings, to which group the carcinogenic hydrocarbons also belong.

I have now succeeded in preparing various salts from these hydrocarbons such as coronene, 1 : 2 benzperylene, 3 : 4 benzpyrene, and anthracene with different acids (perchlorate, sulphate, pyrophosphate) as anions. As indicated earlier[1] these salts are formed from the hydrocarbons by an oxidizing agent, such as a chromium trioxide, potassium ferricyanide or hydrogen peroxide, in the presence of the fairly concentrated strong acids at room temperature. Many of these hydrocarbons are oxidized even by molecular oxygen, yielding the same oxidation products. The sulphates are more difficult to prepare because conditions must be found where no appreciable sulphonation of the hydrocarbons takes place. However, it seems that deeply coloured (water-soluble) salts are formed even from the sulphonated hydrocarbons.

The perchlorate of anthracene is the lowest of the series which has been prepared so far. It shows some of the characteristic properties of these new compounds, which are given in the following :

Anthracene perchlorate, $[C_{14}H_{10}]^{+}[ClO_4]^{-}$. Found: C, 60·9; H, 3·2; Cl, 12·5; $C_{14}H_{10}ClO_4$ requires C, 60·6; H, 3·6; Cl, 12·8 per cent; dark brown fine crystals, recrystallized from acetone-methyl alcohol (1 : 1) decomposes before melting above 110°. Very soluble in acetone with deep brown colour (absorption spectrum, see below). The solutions in acetone are good conductors of electricity. Electrolysis takes place and a deposit is formed at the cathode. Also soluble in ethyl alcohol and benzene. Whereas the salts of the higher molecular hydrocarbons are stable in the presence of water, anthracene perchlorate is decomposed by water, particularly in solution. The perchlorates are all easily decomposed by heat.



ABSORPTION SPECTRUM IN THE VISIBLE REGION OF ANTHRACENE PERCHLORATE IN ACETONE SOLUTION.

The deep colour of the solutions is due to the positive hydrocarbon ion, as is to be expected on theoretical grounds. Under the conditions studied, monovalent ions have been observed ([hydrocarbon]+ [anion]−), although the formation of divalent hydrocarbon ions does not seem unlikely in certain cases.

We have further been led to investigate the structure of the well-known hydrocarbon polynitro compounds (for example, hydrocarbon picrates). These compounds have hitherto been regarded as 'polarization aggregates', although Hammick[2] and Gibson and Loeffler[3] have already suggested that an 'electronic shift' takes place in the case of the corresponding amino compounds. On the basis of the above considerations, we have come to the conclusion that these deeply coloured polynitro compounds are present to an appreciable extent as ionic compounds of the general formulæ : [hydrocarbon]+[nitro compound]- and [amino compound]+ [nitro compound]- in those cases were the molecular ratio is 1 : 1 or as divalent ions ; for example, [hydrocarbon]++ [nitro compound]$_2^-$, where the molecular ratio 1 : 2 prevails. This explains their deep colour, and the rates and mechanism of their formation and decomposition, and is compatible with the observed heats of formation.

The crystal structure of these compounds and the crystallographic distances (3–3·5A.) between their constituents can now be easily explained on the basis of ionic crystals of a somewhat salt-like character as discussed above. The sodium chloride type of structure has actually been observed in the system acenaphthene - 2,6-dinitro - 1,3-xylene[4] whereas in many other cases[5] we find the 'layer lattice' type, as is to be expected when the ions differ appreciably in their size and polarizability.[6]

The importance of these ions is not confined to their appearance as intermediate products in various reactions concerning conjugated systems (oxidation, polymerization, etc.) but may open new possibilities in organic synthesis and give a deeper understanding of their biological action.

A full report will be published elsewhere.

I wish to express my thanks to Prof. G. R. Clemo, and Prof. J. W. Cook for valuable discussions and specimens of hydrocarbons.

VEGETABLES AS FOOD

BY DR. MAGNUS PYKE

THE low mechanical efficiency with which a steam engine converts heat into energy is perennially shocking to each generation of schoolboys, but the wastefulness of the steam engine is nothing compared with the waste of vitamin C which takes place between the time a green vegetable is harvested and its final disappearance from the diner's fork. A cabbage bought at the market may perhaps be expected to contain 60 per cent of its original vitamin C content, the housewife probably throws away no more than 20 per cent of the remainder in preparing the vegetable for the pot, leaving 40 per cent of the original vitamin. During boiling, however, although a negligible proportion is destroyed by the heat, about 65 per cent is extracted by the cooking water and usually thrown away. Thus 17 per cent of the vitamin C with which the cabbage left the field is all that remains when it reaches the table, and if the dish is kept hot before being served even this small residue quickly dwindles to extinction. In 1940, one and a third million tons of green vegetables were produced in Great Britain. From this crop roughly 650,000 kilograms of ascorbic acid, or almost exactly the amount needed to satisfy the physiological requirements of the entire population for a year, was lost.

To the canner it would be thought was presented the opportunity of stopping at least some of these great losses. For him there is the minimum delay between harvesting and processing. The crops are grown to suit him so that loss in preparation for cooking must be small. Cooking, one would think, was inside the tin so that the principal loss by extraction could be avoided. However, the canner, it seems, must do what he should strenuously eschew. He plunges his vegetables for 1½–20 minutes into nearly boiling water before he puts them in their tins and thereby loses the bulk of the vitamin C. Blanching, he calls it, and advances five technological reasons for doing it: but what a pity!

It was at the discussion on April 9 of the nutrition panel of the Society of Chemical Industry on "Vegetables as Food" that these points arose. Miss Mamie Olliver reported one experiment after another of her own unpublished work showing the devastating effect of cooking on the vitamin C in vegetables, and Mr. W. B. Adam concluded that canning affects the nutritive value of vegetables equally as domestic cooking.

Although root vegetables may provide carbohydrate, and green leaves supply protein of useful quality, and although pulses contribute calories, carbohydrate and second-class protein to the diet, vegetables are primarily useful as sources of vitamins A and C and iron and calcium. If the proportions of the day's requirements of each of these four factors in 4 oz. of any vegetable, cooked or raw according to how it is customarily eaten, are plotted one above the other as a column in a graph, a measure of the excellence of the article as a protective food is obtained. A series of vegetables graded in this way and arranged in order of merit is instructive. First come the green vegetables, broccoli tops, watercress, mustard and cress, Brussels sprouts and spinach, rich in carotene, very rich in vitamin C, and containing useful contributions of iron and calcium, although it is doubtful whether the calcium in spinach is utilizable. Next come cabbage and cauliflower, which still contain substantial amounts of vitamin C but negligible quantities of carotene. In green vegetables carotene is associated with greenness; when the heart of a cabbage is blanched it thereby forfeits its rank in the highest class of 'protective' vegetables. Tomato and lettuce fall in the middle of the list. They contain more carotene but much less vitamin C. The vegetables at the bottom of the list, one-fifth as concentrated as the greens, are turnips, green peas, radish, leeks, parsnips, string beans and onions. Asparagus, cucumber, celery and marrow contain so little of vitamins or minerals that they cannot be graded at all.

How does the carrot stand in such company? Carrots contain carotene, but I have presented figures which showed that although 4 oz. of boiled carrot contains as much carotene as the same amount of boiled Brussels sprouts, this was less than half that in spinach, watercress or broccoli. Carrots besides possess a mere 5 per cent of the vitamin C in the green vegetables and a fraction of their available iron and calcium. Even Dr. Leslie Harris, who asserted that the carotene in carrot can equal or excel that in the best green vegetables, cannot thereby promote it to a rank of equality with them in general excellence as a protective food.

The leading vegetable of all those mentioned at the discussion was 'broccoli tops'. McCance, Widdowson and Shackleton introduced the name to the scientific world when they analysed their samples in 1936, but agriculturists, even guided by a botanical designation, found the term ambiguous. Five London greengrocers approached during an interval in the discussion under review produced three different plants identified respectively as 'purple sprouting broccoli', 'white broccoli' and 'winter cauliflower'. Miss Widdowson expressed the belief that none of these was the 'broccoli tops' reported upon in the literature.

In planning war-time vegetable production there is more to do than identify and grow the crops of highest nutritional value. Yield per acre, hardiness and popularity must all be considered. Cabbages which produce heavy crops are tolerated by the public. Brussels sprouts are liked. Although education and shortage can drive people part of the way towards eating what they do not like, palatability is nevertheless important.

Dr. H. V. Taylor showed how war-time vegetable production has been organized to comply with the suggestions of the Scientific Food Policy Committee. A supply of green vegetables has been assured all the year round, the acreage of carrots has been doubled, greenhouses devoted in peace-time to the growing of flowers have been converted to tomatoes and so on. Now, however, the army, the navy, the air force and the general public are insistently crying out for a vegetable product of negligible dietetic value, namely, pickles. In 1941, therefore, it has been decided to plant several thousand acres of land with onions for pickling, with garlic, cauliflower, gherkins, red cabbage and mustard. Will science say that the decision is wrong ?

When the figures are compared side by side, green vegetables are more substantial providers of vitamin C than any fruit except black currant. Thus in war-time they can readily take the place of the oranges and lemons which no longer reach us. According to the analytical figures for carotene, besides supplying the full physiological requirement of vitamin C, green vegetables can also provide all the vitamin A we need. Here is, however, a topic on which further investigation is required. To what extent is the carotene present in each plant physiologically active as vitamin A, and what proportion is absorbed by the body ? Even if only 40 per cent of the carotene present in a 4-oz. portion of watercress is physiologically available, it will still provide 50 per cent of the total daily requirement. In spite of the lack of clear-cut evidence on the vitamin A activity of each vegetable, there are, therefore, grounds for asserting that the full vitamin A needs of the body could be supplied by vegetables should circumstances ever require it.

Besides their importance as protective foods, vegetables could play other minor parts in war-time nutrition. A temporary glut of carrots, for example, if dried would provide palatable carbohydrate. Although perhaps more physiological work is needed on the biological value of green leaf protein, Sir John Russell, from the chair, agreed with the weight of current scientific opinion that its value is high. Preparation of purified vegetable protein might thus provide a valuable addition to the national food supply.

The Society of Chemical Industry's discussion showed that many lacunæ in the knowledge of the nutritive value of vegetables exist. Planning of vegetable production even when guided by scientific advice is a difficult task which may never reach perfection. The crucial rôle of green vegetables is to provide almost alone in war-time the whole dietary requirement of vitamin C. Research on the physiological availability of leaf carotene is not of equal importance. Just as a population is immunized against typhoid for six months or more by a single treatment, so can a country be protected against vitamin A deficiency for a winter by a single dose. The daily requirement of vitamin C, however, must be acquired daily. This is where work, investigation, inspection and analysis at every point must be organized. The Forces equally with the civil authorities must never be satisfied with calculations from a book of tables to insure the nutritional adequacy of food supplies. The men at a mess where the best scientific information had been applied to perfect their diet were found, when submitted to a saturation test, to be grossly deficient in vitamin C. Communal catering tends to increase the times during which dishes are kept hot, a process destructive of vitamin C.

The chemists met the botanists, the dietitians and the administrators to their mutual benefit. The national interest would be served by the further penetration of scientific workers into the market, the communal feeding centre and the canteen.

THE BRITISH PHARMACEUTICAL CONFERENCE

THE seventy-eighth annual meeting of the British Pharmaceutical Conference was held at Conway Hall, Red Lion Square, London, on April 16. With a single day, instead of the best part of a week as in peace-time, the proceedings were severely curtailed, but in addition to the chairman's address, twelve papers were presented at the science session, and although only summaries of them were actually read, the full papers will be available in the official publication of the Conference, in due course. Some of the papers are outlined below.

In his inaugural address as chairman, Mr. A. R. Melhuish dealt with problems affecting pharmacists in their capacity of servants of medicine and servants of the State. He spoke, to use his own phrase, as "a workaday practising pharmacist", and advised his colleagues that they would be doing more for the medical services of the country if they devoted more attention to those fields of activity which do not involve legislation, than if they spent time in striving for such politically unattainable goals as the reservation to them of the sale of all medicines. He impressed on them the importance of 'personality'; the greatest asset for the individual pharmacist in the future, he said, would be his individuality.

Two papers related to ergot. One of them, by C. H. Hampshire and M. W. Partridge, was from the laboratory of the British Pharmacopœia Commission, and the second, by N. L. Allport and N. R. Jones, from the laboratories of the British Drug Houses, Ltd. The first consisted of notes on the extraction and decomposition of the alkaloids; it showed that neither continuous extraction of ergot with methylene dichloride nor shaking ergot with menstruum of ammoniacal acetone completely extracts the alkaloids, which are completely extracted, however, by continuous extraction with anæsthetic ether. In the second paper, the authors described a rapid method for the determination of ergometrine and ergotoxine.

A paper, by H. Berry, from the College of the Pharmaceutical Society, on the components of acriflavine, was summarized by the author as follows: (1) the bacteriostatic value of the two active components and mixtures of these in varying proportions have been compared against certain organisms; the results show little variation; (2) there is no evidence of a bacteriostatic or physical character of any definite combination between the two components; (3) it is suggested that proflavine or the neutral hydrochloride of 2 : 8-diaminoacridine should replace acriflavine for surgical use.

A second paper, by F. Wokes, from the College of the Pharmaceutical Society, had as its subject "The Subcutaneous Implantation of Thyroxine Tablets". The author suggested that great caution be employed in the implantation of thyroxine tablets in human subjects, and that preference be given to the oral administration of thyroid, which appears to be much safer and more effective.

A paper, by A. M. Briggs and D. E. Callow, from the Evans Biological Institute, dealt with the preparation of sterile solutions of procaine hydrochloride. The author's conclusions are that sterile solutions can be prepared without the use of bacteria-proof filters, provided aseptic methods are used. Solutions prepared with an antiseptic present are not vulnerable to contamination likely to occur in a laboratory devoted to the production of sterile preparations. Solutions prepared with both an antiseptic present and an oxidation-preventive substance such as sulphur dioxide are even less vulnerable to contamination. The antiseptic properties of solutions of procaine hydrochloride tend to increase with increase of percentage strength.

A second paper, by G. E. Shaw and H. G. Hind, from the Evans Biological Institute, was on "Some Aspects of the Storage of Antitoxins During War-time". Antitoxic serum, the blood serum of hyper-immunized animals, is issued for sale either in its natural state or, more usually, as a solution of a selected protein fraction therefrom; it is of special importance in war-time owing to the exposure of the population to risk from epidemic disease and the occurrence of a large number of injuries which necessitate antitetanic treatment. Antitoxin is stored in a sterile condition at about 4° C. in large glass containers. In view of the risk from damage through enemy aerial activity, bulk storage presents a serious problem, owing to the possibility of containers breaking and the supply of electricity to the refrigerator plant being interrupted. The authors sought for a method which would eliminate the need for glass containers, and make the use of refrigeration unnecessary, but would, at the same time, preserve the potency and maintain the sterility of the product. They described two methods, each yielding a dry powder which may be stored in any type of container. The potency of the product is maintained. Cold-storage accommodation is unnecessary, and the powder is self-sterile. The desiccation method requires special apparatus for drying, but this does not involve a large capital outlay. The material contains so much preservative that, although reasonable care in handling is naturally adopted, complete asepsis is not essential.

PHOTOPHORES IN DECAPOD CRUSTACEA

DR. R. DENNELL'S work on the structure of the photophores in certain decapod crustacea from deep water is of outstanding interest and importance*. It has been known for long that luminous organs exist in many of the deep-sea decapods; but it is astonishing to find such a variety of structure and so much difference in closely related forms.

The photophores described in this work are not all proved luminous organs, but morphological evidence makes it extremely likely that this is so. Only in a few cases have live animals been seen to emit light, but those who have observed the phenomenon have made careful notes of the position of the light organs, and in these cases it is certain that true photophores are present. The reason for the luminescence is still obscure. As in the squids and fish which possess them, the luminous organs mostly throw their light downwards, lighting an area outside the field of vision, it is especially difficult to understand why in nearly all species of Sergestids examined, and also in Parapandalus, some of the photophores should be situated in such a position that they must illumine the branchial chamber and throw light downwards on the gills. There is nothing in the structure of the gills themselves to show that they could benefit from such illumination, and it may be as is suggested (but with serious objections) that the development of light-organs here is simply the response to a rich oxygen supply.

Within the genus Sergestes no fewer than four different types of photophores are found: (1) The organs of Pesta which occur in the larger number of species and are modified liver tubules of endodermal origin; (2) complex organs with lenses scattered superficially on the body which are found in *Sergestes challengeri* and its allies; (3) superficial simple organs without lenses scattered over the body as in *S. regalis* (this being an entirely new type of luminous organ); (4) simple superficial streaks on the carapace which are found to be present in those species which also possess the organs of Pesta. The second and fourth of these are of ectodermal origin, the third may be ectodermal, or, possibly, mesodermal. It is shown that the structure of the photophores in the various species of Sergestes may be entirely different and that it is unsafe to conclude that any are similar unless the minute structure is examined, even if they are in the same position.

In *Parapandalus richardi*, which with some other pandalids possesses photophores outwardly like the main bodies of the organs of Pesta of Sergestids, these organs have a totally different minute structure. It is a remarkable fact that such similar organs should have been separately evolved in the two groups; it shows that they must subserve some important function, if, as yet, not sufficiently understood. There are also in Parapandalus organs on the pleopods which are doubtfully designated as photophores.

In the Hoplophorids the photophores have reached a very high state of complexity, and here again a variety of types is shown, movement being well developed. The pleopod organs are very similar in all the species of Hoplophorus and Systellaspis examined, but the other types occur very irregularly; photophores in similar positions in two species are frequently entirely different in structure, while in a single species a number of different types of organ is to be found. For the most part the various kinds of organ are entirely distinct and they do not form stages in a developmental series. It is a remarkable fact that the luminous streak behind the fifth leg, which is a conspicuous feature in both Systellaspis and Hoplophorus, should have an entirely different structure in these two closely related genera.

The present investigation is a purely morphological one, but it is impossible to describe these organs of such unusual diversity without touching on their probable function and methods of working. The remarks made are suggestive and cry aloud for more work on this extremely interesting subject.

In conclusion, tribute must be paid to the very excellent technique and quality of the illustrations throughout.

---

* On the Structure of the Photophores of some Decapod Crustacea. By Dr. Ralph Dennell. Discovery Reports, 20, 307–382, plates XXIV–XXVI (1940).

FORTHCOMING EVENTS

Saturday, April 26

North of England Institute of Mining and Mechanical Engineers (in the Lecture Theatre of the Institute, Newcastle-upon-Tyne), at 2 p.m.—Mr. R. D. Beilby: "The Prevention of Gas-Ignition in the Overcut".

Monday, April 28

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. G. Stafford Whitby: "Chemotherapy", I.

Tuesday, April 29

Institution of Civil Engineers (at Great George Street, London, S.W.1), at 1.30 p.m.—Prof. E. N. da C. Andrade, F.R.S.: "The Mechanical Behaviour of Solids" (Forty-seventh James Forrest Lecture).

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 4.15 p.m.—Mr. H. H. Coghlan: "Prehistoric Iron prior to the Dispersion of the Hittite Empire".

Wednesday, April 30

Physical Society (Colour Group) (at the Royal Photographic Society, 16 Prince's Gate, London, S.W.7), at 2.30 p.m.—Mr. H. D. Murray: "Colour Terminology".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. O. R. Tisdall: "The General Practitioner and Scientific Thought".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 4.30 p.m.—Major H. C. Gunton: "Report on the Phenological Observations in the British Isles from December 1939 to November 1940".

Thursday, May 1

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Dr. Agnes Arber: "The Tercentenary of the Birth of Nehemiah Grew".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Engineering Subjects—The Principal, County Technical College, Worksop, Notts. (April 30).

Lecturer in Physics and Mathematics at the Harris Institute—The Principal, Technical College, Corporation Street, Preston (May 2).

ANGLO-AMERICAN COLLABORATION FOR DEMOCRACY

DURING last summer, in the early stages of the Battle of Britain, the Prime Minister was reviewing the first year of the War and spoke in homely terms of the English-speaking democracies, the British Empire and the United States, having "to be somewhat mixed up together in some of their affairs for mutual and general advantage" ; some time earlier, a manifesto issued on behalf of American men of science, like an earlier resolution of the American Association for the Advancement of Science, had frankly recognized the relation of science to freedom of thought and speech under democratic institutions, and the need for men of science to draw closer together in defence of democracy. The offer of naval bases to the United States, which prompted Mr. Churchill's reference, was only a stage in the development of the association of interests for common purposes between Great Britain and the United States which had already commenced before the War, and which has recently been further recognized by the request from the American Association for the Advancement of Science to the British Association for collaboration in the formulation of an international charter of democracy (see NATURE, April 12, p. 448).

The process which the Prime Minister so warmly welcomed last summer has gathered impetus. In accepting the nomination of the Democratic Convention for election to a third term of office as President of the United States of America, Mr. Roosevelt affirmed the determination of his countrymen to maintain unswervingly in foreign policy sympathy and moral and material support for all free peoples. In subsequent speeches down to the historic speech to the White House Correspondents' Association on March 15, following the passage of the Lease-and-Lend Act, the President has repeatedly indicated how clearly the United States appreciates the great issues which are at stake in the present struggle, and the growing determination of that great democracy to afford not merely sympathy but also the maximum possible support in arms, ships and food which are required by those who now hold the bridgehead of freedom and humanity's hopes.

Nor have Mr. Churchill and President Roosevelt been alone in making it clear, in speeches that have brought the two great democracies closer to each other than ever before in their history, that the two peoples are threatened by the same danger. It was a happy choice that brought a former director of the International Labour Office across the Atlantic to represent the United States in Great Britain, and Mr. Winant's address at the Pilgrims' luncheon has already shown how well qualified he is to interpret the common ideals and basis of our civilization, and to promote that co-operation which in this interdependent world is the only alternative to domination or disaster—the co-operation of free peoples to overcome the fear of domination which has brought so much grief to this generation. It is indeed permissible to see in Mr. Winant's appointment the symbol of American acceptance of a common duty to the world.

Viscount Halifax, in his turn, has given equally happy expression to the Anglo-American unity of purpose which has been sealed by the passage into law of the Lease-and-Lend Act. This noble interpretation of the principles which are essential to life as we wish to live it and to see it lived, has been as welcome and inspiring on this side of the Atlantic as to those entering on the new and strenuous programme of aid for Britain to whom his words were primarily addressed. Lord Halifax demonstrated the complete agreement of the British Government with the purposes President Roosevelt described with such vivid force in his speech a few days earlier.

There is every reason to believe that, in the pursuit of this common purpose, the two democracies may find a tie that will make them effective reformers and champions of liberty. Nor is this all. Lord Halifax, like Mr. Winant, looks forward to the post-war world : "This business of rebuilding after the War will be a task far beyond the strength of any single country." New needs will demand new remedies, and there will be room alike for all the courage and imagination of youth and all the clear thinking of experience that can be rallied to the task. No tyranny will frustrate the Anglo-American co-operation that is seeking to win a free world, but even more significant for humanity may be the awakening of the two peoples to the immense responsibility that will rest upon them. In the words of Pascal, to "combine justice and power, making what is just strong, and what is strong, just", may deserve and win the support of all other peoples likeminded with ourselves to strengthen the foundations of world society.

The future structure of the community of nations cannot yet be clearly seen. Much indeed may be learnt from a careful study of the past, and it is already clear, from the discussions of the last two years on different proposals for a federal world, that whatever form of co-operation is to succeed must be based on a real community of interests, and on ideals which are widely shared ; further, it must command an allegiance which is prepared to make real sacrifices, both individual and corporate, in their defence and service.

It is this that gives particular significance to the three recently published slight volumes*. Dr. Butler's three essays on "True and False Democracy", delivered more than a generation ago, are as full of meaning for Great Britain to-day as when they were delivered in California, in Michigan and in Buffalo. Together they indicate the dangers which democracy has to face in either country, and the great community of democratic institutions which is the heritage of both. We have indeed reason to be grateful that the two nations have leaders and representatives on both sides of the Atlantic who are able to undertake so ably and inspiringly the vital task of education on which Dr. Butler lays his main stress. Prof. J. B. Conant's recent visit to Great Britain has disclosed the extent to which American men of science, as has long been known to their scientific colleagues, are actively with us in our war effort.

Dr. Butler's able analysis of the weakness and strength of democracy leads indeed to the conclusion that, had due attention been paid to such warnings, we should never have had to face the present stern challenge to liberty. It is not the United States alone that has need of an aristocracy of intellect and service. The paucity of genuine thinking and neglect of, or indifference to, electoral and social responsibilities among the citizens of the democracies are among the main reasons for the straits in which we are now placed. Dr. Butler's analysis is more searching than Lord Davies's somewhat bitter indictment of leadership in Great Britain, for an electorate accustomed to think for itself, to face facts and accept responsibilities, would not have been slow to rid itself of incompetent or hesitant leaders. It is the moral basis of democracy that is all-important, and necessitates such untiring attention to the education not merely of public opinion but also of the individual citizen. Without that basis, democracy is indeed effete in the face of the totalitarian regime. From it, as Mrs. Roosevelt shows so clearly in her admirable little book, must come the driving force which will call forth the effort required to establish beyond the threat of force a permanent democracy with its background of spiritual belief.

The great merit of Mrs. Roosevelt's incisive contribution is that it sets forth with admirable lucidity the fundamental issues that are involved in real democracy—the difficulty of achieving a balance between planning and freedom, and the particular challenge to youth, and all that is involved in the acceptance of that challenge and those responsibilities. Democracy, she urges, is a method of government conceived for the development of human beings as a whole, and this dynamic conception involves more than fulfilling our duties as citizens, seeing that our nation is truly represented by its Government and that the Government is responsive to the will and desires of the people.

---

* True and False Democracy. By Nicholas Murray Butler. Pp. xiv+111. (New York : Charles Scribner's Sons, 1940.) 1.25 dollars.

The Moral Basis of Democracy. By Eleanor Roosevelt. Pp. 62. (London : Hodder and Stoughton, Ltd., 1941.) 6*d*.

Foundations of Victory. By Lord Davies. Pp. 192. (London and Glasgow: Wm. Collins, Sons and Co., Ltd., 1941.) 2*s*. 6*d*. net.

That will and desire must be made the result of adequate education and adequate material security. We must maintain a standard of living which makes it possible for the people really to want justice for all, rather than to harbour a secret hope for privileges because they cannot hope for justice. Moreover, from this dynamic conception and practice of democracy, there flow not only a gradual rise in the standard of living of all the people, but also that constant sense of vigilance and alertness which makes life an adventure and gives a continuous appeal.

Mrs. Roosevelt's moving picture of the spiritual values of democracy should enlist the warm sympathy of all forward-looking minds, on both sides of the Atlantic. In itself, her book is evidence of how firm are the moral and spiritual foundations upon which may be built the practical schemes of Anglo-American co-operation to which the last, and perhaps most important and suggestive, chapters of Lord Davies's book are devoted.

The central theme of Lord Davies's book is that this is a civil war against a revolutionary movement seeking to impose a new order upon Europe, and that accordingly victory depends upon diplomatic as well as upon military strategy. It is not even sufficient to direct our efforts to the maintenance of morale in Great Britain. The defeat of the enemy cannot be separated from his defeat in the moral and spiritual arena. It is for this reason that Lord Davies thinks our diplomatic efforts should be concentrated in proclaiming our war aims, in order to secure their acceptance by world opinion. Foreign policy and war aims are an integral part of the strategic plan.

Lord Davies insists that the decisive factors in this struggle are war aims and air power. "The former is the rock upon which our morale, our determination to win, rests. The latter is the instrument through which victory can be achieved." He believes that our supremacy in the air can only be achieved with the active assistance and co-operation of the United States, and that Anglo-American co-operation will win the War because their basic peace aims—the suppression of war and liberation of oppressed peoples—are identical, and because their mastery of the air and command of the sea give them the power to insist upon this new order.

Lord Davies recognizes that the basis of Anglo-American co-operation lies in their heritage of representative institutions. Great Britain is the cradle of representative government, the United States the nursery of federalism. The foundations of a lasting peace are to be discerned in the common ideals, the mutual understanding, identity of interests and closest collaboration of the English-speaking peoples. Already the British and American peoples are closer together than were France and Great Britain when the British Government offered the people of France a permanent union on the basis of a common citizenship. Anglo-American co-operation on a broad front is growing rapidly with the war effort of the English-speaking peoples, and Lord Davies visualizes some form of political union of the English-speaking peoples which would hold the peace during the interval, possibly of several years, between the cessation of hostilities and the summoning of a peace conference to review the settlement. Acceptance of such responsibilities by the two great democracies would afford opportunity for real reconstruction, during and after the transitional period, the development of an abiding settlement and some sort of European order or federation.

Lord Davies looks to the existence of resurgents in the numerous countries under Nazi domination to promote such developments as well as to assist in the physical overthrow of the Nazis in the later stages of the War. He would see our foreign policy directed to exploit these possibilities as actively as possible, and would enlist in an international force the numerous allied contingents at present in Great Britain. We should use to the full every opportunity of explaining as widely as possible our fundamental war aims and purpose.

Lord Davies has written a timely book. It offers a challenge to the intelligence and character. which, as Dr. Butler remarks, a triumphant democracy must possess. Slight as they are in volume, these three books offer no mean contribution to the task of education which is so imperative for the maintenance of morale, and to the consolidation of victory, and to that constructive and creative thinking upon which reconstruction and the evolution of any new world order must ultimately be based. Their appearance at this point is indeed a happy augury that the American and British peoples, acting under the inspiring leadership they now possess, will write a new and more splendid chapter in their own history and in that of the world.

AGRICULTURE IN PRACTICE

Soil and Sense
By Michael Graham. Pp. 274. (London: Faber and Faber, Ltd., 1941.) 7*s.* 6*d.* net.

THIS is a most fascinating and instructive book. Its author lays no claim to be either a farmer or a man of science. Yet this illuminating little treatise on several outstanding aspects of modern husbandry contains much stimulating food for thought for those engaged in, or inclined to embark upon, agricultural pursuits; and if 'organized common sense' is still a permissible definition of science, it may not unjustly be included among the manuals of science, as applied to our most vital industry.

It is indeed worthy of a wider clientele, especially at a time when the exigencies of war are establishing, through the process of evacuation, unprecedented contacts between our urban and rural populations. It is calculated, in its breezy conversational style and with its homely metaphors, epigrams and maxims, to stimulate the imagination, and evoke the interest, of the veriest Cockney in the attractions and multifarious activities of Britain's countryside. It exhales the pure atmosphere of a fuller life (especially to those of keen observation like the author himself), than material wealth or an urban environment can possibly bestow. For colourful word painting few modern works of practical utility can bear comparison with its earlier chapters. At the same time its useful lessons are expressed in delightfully popular phraseology far removed from the technical jargon which makes so many English agricultural textbooks inexpressibly dull to the layman. It is fertile in appropriate similes provided out of a storehouse of cultured and versatile knowledge. Seldom indeed has a more attractive medium for absorbing the rudiments of an agricultural education, without intellectual effort, seen the light.

Prefacing his first chapter with excerpts from a typical old farm agreement, the author convincingly and mercilessly exposes, by sound scientific reasoning, and without any display of partisan bias or personal prejudice, the dangerous and myopic fallacy of scrapping—under the political watchword "Freedom of Cropping"—the checks upon soil exhaustion imposed by the restrictive covenants in these old documents, and then ploughing in old turf to restore temporarily the productivity of the starved land. Not that he objects to ploughing in turf. Indeed he welcomes it, so long as it is the half-formed turf of a temporary "ley" (or "lea") such as was initiated some fifty years ago on the Holkham estates of the late Lord Leicester, as a modification of the four- or five-course rotation, developed and expounded twenty years later by Mr. R. H. Elliot under the title of "The Clifton Park System of Farming", and in more recent years effectively popularized, through precept and practice, by Sir George Stapledon, director of the Welsh Plant Breeding Station at Aberystwyth. His theme is, in fact, soil fertility, and the manufacture (by organic and other agencies) and maintenance of humus as the basic condition of its availability to plant life. He recognizes, as did so forcibly the late Prof. Henry Armstrong, the lack of phosphates in the average British soil, but questions the wisdom and the economy of applying basic slag or other phosphatic fertilizers, to the extent usually advocated, in order to make good the deficiency. Climatic shortcomings and leaching may, he opines, defeat the object in view. He regards, as Elliot did, continuous doses of artificials and of lime (in the absence of adequate humus) as conducive to soil exhaustion.

His remedy, like Elliot's, is the employment, in "ley" making, of herbage plants of varying depth of root, and especially of chicory and other deep-rooted herbs. It is, he avers, "the solvent action of the knotting of roots that liberates minerals from the large reserves of even the poorest soils". This problem of maintaining humus and soil fertility under modern systems of husbandry (especially now that motor traction has robbed us of much of the animal manure formerly available) and the extent to which chemical fertilizers can provide manurial requirements, is a subject upon which experts are not wholly agreed. This being so, what purports to be the "common sense" view (ably propounded by the author) merits respectful consideration. It is without doubt true that, in the absence of humus or vegetable matter, lime may prove an exhausting agent, even on "sour" soils. In regard to other mineral dressings the exhaustion, if any, is likely to be caused by seriously upsetting the balance of the manurial constituents of the soil. This has been demonstrated in some parts of New Zealand—which has the finest and least adulterated pastures in the world—by excessive applications of nitrogenous fertilizers in areas suffering from serious phosphate starvation. Incidentally, the illustration (on p. 122) of Mr. Graham's book showing the "mining" activities, at different depths, of the roots of different plants (thus assisting soil aeration and the passage of water) is particularly instructive.

There is no doubt that, although less fertilizer is employed by the average small farmer in Great Britain than in many other countries, much money is wasted by those who can least afford it under the mistaken impression that the same medicine, provided by the chemist, is applicable to all soil and plant requirements. Much, too, is applied wastefully to ill-drained, or waterlogged, land. On these subjects the author directs the would-be husbandman along the path of wise discrimination. In connexion with ley-farming—a subject very apposite to war-time food production in Britain—Mr. Graham makes the surprising, but illuminating, statement that "grazing by *bullocks* is an essential part of grass-farming, without which ley-farming may not be successful". "There is no evidence", he says, "that this sort of farming can be carried out successfully without good hard grazing of the leys by mixed stock. The men who have done it have always grazed hard and well. . . . There seems every reason to think that ley farming will be a failure unless keeping store cattle is a success", and he goes on to say "the bullock . . . must be made profitable *somehow*. . . . Our food supply depends on how he eats grass and what he leaves behind him." This is a view that deserves greater consideration than most of our "arable dairying" enthusiasts have yet vouchsafed to it. The puzzle will be to make the fatting bullock a continuously profitable proposition.

No small portion of this book is devoted to an instructive dissertation on grassland, its constituent plants (gramineous, leguminous, and herbal) and their respective peculiarities, seasonal appearance, relative values and manurial needs. He describes cocksfoot as "the king for ley farming"—although of less feeding value than rye-grass—because it has a deeper root system. The selective grazing of animals, particularly horses, is interestingly noted. Too little perhaps, in view of its deep roots and high protein content, is said about lucerne, or alfalfa, the most valuable fodder crop in the world. The penultimate chapter entitled "Britain as one farm" deserves special study under existing war conditions. In it he summarizes the contentions of previous chapters, advocating a more comprehensive planning of the nation's agriculture to supply the nation's needs and a more economic system of utilizing available implements and labour over larger areas than existing farm units.

Among the author's captivating dicta and slogans are the following: "A good tenant is worth more than a high rent"; "the least skilled man on a farm needs more wit than the 'labourers' of other industries"; "Subsidize wages and drop all other subsidies"; "The money should go to good farmers who feed the land, as tradition says it should be fed, and none should go to those who merely exploit it"; and finally "We are surrounded by a world of nonsense, built out of pieces of sense, put together wrongly. This nonsense world has too much chemistry, forgetting the living earth." Perhaps he is right. At any rate the dictum justifies the title of the book. BLEDISLOE.

GEOLOGY OF COAL

Geology of Coal
By Otto Stutzer. Translated and revised by Adolph C. Noé. Pp. xiii + 461. (Chicago: University of Chicago Press; London: Cambridge University Press, 1940.) 30*s*. net.

THIS volume is largely a translation of Stutzer's well-known work, "Allgemeine Kohlengeologie", but includes a certain amount of revision of the German text by Stutzer himself and much new material, mainly concerning American coalfields, by the late Dr. A. C. Noé, of the University of Chicago. It is designed to supply geologists, mining engineers and others interested in the coal industry, with a full and authoritative account of the many and varied geological problems connected with coal deposits. These are treated broadly in successive chapters dealing with chemical and physical properties of coal, microscopic examination of coal, origin of coal, processing of coal, origin of coal beds, stratigraphy of coal deposits, petrography of coal beds, and disturbances affecting coal beds. Each chapter has its own list of references.

For the first time Stutzer's work is made available in an English translation, and the present edition will certainly find a place on the bookshelves of all who are interested in the geology, mining and technology of coal deposits. The publication of a book of this nature, in which data and illustrations from world-wide sources are brought together, and to the preparation of which a vast amount of research and labour has been devoted, will be widely welcomed by coal geologists as a comprehensive account of the problems in which they are interested. It is alike informative, stimulating and challenging. The general plan of the work seems admirably designed, and with the help of a detailed table of contents and of adequate indexes to subjects, authors and places, the reader has little difficulty in finding any particular subject or reference he may wish.

It is claimed that in the present edition Stutzer's work has been revised and brought up to date. It would, however, be difficult to justify this claim in its entirety. The chapters dealing with the origin of coal, the origin of coal beds, the stratigraphy of coal deposits and the disturbances affecting coal beds, which together make up approximately half the volume, have no references later than 1935, and only six later than 1930. It is disconcerting to find that the very short chapter (4½ pp.) on the processing of coal is based mainly on a text-book published in Leipzig in 1916. It seems anomalous, again, to find that the only reference to Kidston's researches on the Carboniferous flora is to an early paper of 1885, and British readers will certainly note many other omissions that might well have been included in a work published in 1940. It is a pity, too, that in many cases the information on particular subjects or problems is presented as a series of detached notes rather than as a considered and balanced statement. A compilation of this character cannot be expected to be free from errors, but there are a number for which it is difficult to find a reasonable excuse. The inclusion of a reference to a paper on British Carboniferous stratigraphy in the chapter dealing with the microscopic examination of coal on p. 80, and some very obvious errors on pp. 115, 118 and 366, may be quoted as examples.

These defects, however, can be remedied in any later edition, and certainly the volume now issued is a mine of information on all aspects of coal geology and a notable monument to the patient research and erudition of its authors.

M. MACGREGOR.

CLINICIANS AND BIOCHEMISTS

Biochemistry of Disease
By Prof. Meyer Bodansky and Dr. Oscar Bodansky. Pp. x+684. (New York: The Macmillan Company, 1940). 30s. net.

MOST text-books of clinical biochemistry are written chiefly from the biochemist's point of view, and differ little from text-books of biochemistry proper except that practical details are given of the many laboratory tests that have clinical importance. Their arrangement is also biochemical, and it is unlikely that many readers derive much intellectual enlightenment from studying them, apart from those routine clinical biochemists whose job it is to perform these tests.

The book under review is original in that the text is divided up on a clinical-anatomical basis. The successive chapters deal with diseases of the blood, heart, respiratory tract, kidney and urinary tract, digestive tract, liver and biliary tract, pancreas, adrenals, pituitary, thyroid, parathyroids, bone, muscle and male gonads. There are additional chapters on biochemistry in obstetrics and gynæcology, in disorders of nutrition and metabolism and in neurologic and psychiatric disorders. It is apparent that the emphasis is laid on the clinical rather than on the biochemical aspect of the subject. The book is also original in that the treatment of each chapter is theoretical and factual. There are no details of the chemical methods involved in the performance of the various tests; instead are given the normal results of such tests, the findings in the various pathological conditions and an outline of the theories postulated to explain the abnormal results and the cause of the disease. The clinical procedure adopted in performing the tests is generally described.

Such arrangement and treatment has much to recommend it. It is the type of book which usually meets with the criticism of falling between two stools. If this book does so it falls firmly on its feet, and both clinician and biochemist can read it with profit. Each will know a great deal more about the other's problems when they have finished. Biochemistry is still not as fully used as it might be in the hospital ward, and such a book as this, which stimulates interest instead of imparting a mass of practical detail already available in many previous books, or attempting to teach biochemistry to the uninterested medical reader, should do much to make young clinicians appreciate the necessity of the biochemical tests they have done in the laboratory, and may even persuade them to initiate clinical biochemical researches for themselves.

It should be stressed that the book may be *read* rather than studied, since it is written concisely and lucidly with little of the over-attention to detail that is the bane of many American books. For example, the chapter on the pituitary diseases deals only with gigantism and acromegaly, basophilism, dwarfism, cachexia, adiposogenital dystrophy and diabetes insipidus. To those familiar with the multiple classifications adopted by some clinical endocrinologists in Germany and the

It is grievous to think that a casual lorry should have put an end to a life of such rare distinction and of constant service to his fellow-men ; yet it is well to be able to think that the best was left to the last. Other men might perhaps have done his public work, though not with the same dignity, good judgment and perseverance. But no one can think of a writer and thinker—for many decades back—who could have produced the "History of Europe". It is practically the history of Western civilization and he had dreamt of it and worked at it during the many toils which took him afield. It is full of learning well-arranged and beautiful to read. If Fisher could have included more science and technology it would be a faultless masterpiece. I know people who make a point of reading some of it every day.

F. S. Marvin.

STEPS TO AN ISLAND

The Way to an Island

By R. M. Lockley. (Travellers' Tales.) Pp. xi - 208 + 16 plates. (London : J. M. Dent and Sons, Ltd., 1941.) 7*s*. 6*d*. net.

R. M. LOCKLEY has written a number of books dealing with natural history and life on lonely islands, but he has never written a better book than this. I do not mean that there is a greater wealth of accurate observation in this book : I refer rather to the style. The English is admirable ; it is simple and direct, very vivid and holding the reader's attention from first page to last. It is indeed a book worthy of the most celebrated masters of modern English prose—Masefield would surely read it with pleasure.

Perhaps, although Mr. Lockley has already written so much on his bird-haunted isle of Skokholm, one could wish that more of this book were devoted to his life on that island. But, as the author says, he has described that life in other books and this work deals with his earlier life—his school days, his intense love of Nature, his dream of owning an island somewhere between Lundy and North Rona, his setbacks and the final fulfilment of his dream.

His description of hearing as a boy the wood warbler's song is admirable (p. 65) :

> "'See-ee--ee -ee -ee-ee-ee ! ' cried the wood-warbler in his vibrating voice, and his whole body shivered with delight. A million leaves in the tops of the trees swayed in a rustling chorus which swamped the last sighing notes of the singer. Yes, yes, this is the time we dreamed of in the long wait and coolness of winter, the time of contentment and friendliness and fullest perfection. And with my heart full of a rare joy I waited for the three bell-like notes which concluded the wood warbler's song. They seemed to round off that astonishing magic madrigal by giving utterance to the sadness of replete happiness."

Of his first spring on Skokholm—he had passed the winter in hard work repairing the one house on the island—and his difficulties with the garden the author gives an arresting description. Of the garden he writes (p. 184) :

> "The garden gave me pleasure and anxious moments by turns. Something like a ton of bracken and nettle and blackberry roots had been removed and burnt, and by degrees I had planted the rich loam with currant and gooseberry cuttings, broad beans, peas, shallots, early potatoes, parsnips, and so on. But rabbits had found a way in more than once, and I had lost some cabbages I had put down. Then with the first mild weather thousands of snails crept from the cracks between the stones in the herring-bone patterned hedge wall. The snails found my tender young stuff excellent after the years of grazing on tough bracken, nettle, and weed. I collected them by the bucketful every evening, and threw them into the sea. I had no help from the birds. All the thrushes had left the island with the coming of spring, and the single blackbird and his mate took no interest in snails."

But success crowned his efforts (p. 188) :

> "How the plants grew ! The marrow-stem kale shot up and opened leaves like miniature banana palms. The corn grew shoulder high. The potatoes were huge. The lines of blue chicory and yellow dandelion gave this field-garden a gay look. The wild rabbits came out every afternoon and inspected the garden from without the wire-netting fence."

From Skokholm the author and his wife sailed out to, and lived for a day or two upon, the still more lonely and remote ocean isle of Grassholm, accessible only in very fine weather when the ocean swell is at rest. Here they watched the gannets at their nesting colony, observed the habits of the grey seals, and slept on the long grass on the east (and comparatively sheltered) side of the island where they could see, across the gannet-haunted miles of ocean, their own island of Skokholm rise on the eastern horizon.

Truly, this is a book to take the thoughts off these grim days of strife, and transport the spirit to admirable and lovely things in the serene world of Nature.

Seton Gordon.

United States such a rigid confinement to essentials is very welcome.

The references are well chosen; in general the original paper on any subject is referred to, but only papers of the last ten years are quoted afterwards. All the graphs and tables are taken from original papers. Indications for theoretical reading are apt and full; references to the main review articles by Himsworth, Long, Houssay and Soskin should enable any reader quickly to become conversant with the modern views on diabetes mellitus. The references are also surprisingly up to date. Though most of the work on the chemistry and antihæmorrhagic activity of vitamin K was only done in 1939, the subject is well covered in the book, which is dated March 1940. Such topicality leads one to hope that further editions will be called for at short intervals. Physically the book is well produced, with detailed author and subject indexes, good printing and real binding. The casing adopted by most English publishers is generally quite inadequate to withstand the wear that such books as this may be expected to undergo through constant reference over a period of years.

English readers of American books often seem to find some jarring spelling or syntax offending their pedantic ears. This book compares the size of the pituitary to that of the navy bean. Some future international conference on nomenclature might amuse itself by devising series of internationally recognized nuts, beans, etc., graded according to size for the purposes of such comparisons.

MR. FISHER'S AUTOBIOGRAPHY

An Unfinished Autobiography

By H. A. L. Fisher. Pp. xi + 163 + 4 plates. (London, New York and Toronto: Oxford University Press, 1941). 7*s.* 6*d.* net.

IT was a grievous loss to Oxford and to Great Britain when Mr. Fisher was killed in an accident in London at the beginning of last year. He had written as far as his visit to Canada and New England, and had recovered from the serious breakdown which followed his great work on the history of Europe, which had appeared in a cheap form in 1936 and is a prized book by all who value perfect style and profound knowledge. He had begun to work again with his accustomed vigour and devotion when the accident happened, and we have to add his name to that of the many whom we have lost at this critical time in our history. He would have been a wise counsellor at the many grave moments which have fallen upon us since he passed away. Mrs. Fisher gives in her foreword a touching account of the stream of inquirers and letters which poured into New College in his last years. It was a marvellous life. One can scarcely think of anyone who combined so many activities and performed them all with wisdom and success.

Fisher was born in 1865, and his father, who had studied for the law, was selected by the Prince Consort to be private secretary to his eldest son and spent five years in Court life, always retaining the goodwill and affection of the royal family. On his mother's side he was a Pattle and had through that family both his distinguished appearance and his intimate knowledge of India, with which the Pattles were connected by several branches and various official posts. He thus started high in the social scale, and he widened his knowledge and circle of acquaintanceship by a long stay in Paris after he had finished his course at Winchester and New College. He made two lecturing trips to South Africa and the United States and served on the Indian Public Services Commission (visiting India twice) before he was offered the vice-chancellorship of Sheffield between the years 1913 and 1916. A great deal of public work was interspersed with all this, and it ended in his being asked to join Mr. Lloyd George's Government in December, 1916.

This episode in a marvellous career had almost as many varied experiences as the years which had preceded it. It is too long to describe in detail. The different posts which he was asked to fill at different times in the six years during which he remained with Mr. Lloyd George were the mark of a man of almost infinite capacity, though specially wedded to his first love of knowledge and of modern history. It was as minister of education that he took office and at the Board of Education that he did his chief official work. Secondary education was transformed by the liberal raising of salaries, and a scheme for the extension of the school age with the provision of compulsory continued education from sixteen to eighteen was passed but has not yet been put into force.

Fisher left Sheffield finally in 1918, and the interval from that to the wardenship of New College was filled up with a multitude of useful and always intellectual occupations until the wardenship fell vacant in 1925. New College was his home, study his recreation and the adornment of Oxford his hobby ever since.

The Photismi de Lumine of Maurolycus

A Chapter in Late Medieval Optics. Translated from the Latin into English by Henry Crew. Pp. xix+134. (New York: The Macmillan Company, 1940.) 15*s.* net.

"LIGHT concerning Light", the playful title given by Franciscus Maurolycus (1494–1575) to his short text on optics, suggests a certain sense of humour in the author, a prominent churchman and man of science of his day, which might have saved him from the inconsistency of outlook so painfully apparent from the modern point of view in this book. Mr. Henry Crew's charming translation brings within the reach of all a work which is in itself an eloquent comment on the folly of certain chapters in human thinking, especially the kind of thinking which strays over-far from experience and experiment.

As Mr. Crew remarks in his introduction, Euclid furnished the norm for a scientific demonstration throughout the sixteenth century. The assumptions, the data, the theorem and the logical steps to its establishment had to be set out in order. All is well in the early stages, when the law of reflection starts discussion of problems in geometrical optics, and it is even possible to get some distance in theorems regarding refraction, although only the qualitative and not the quantitative law of refraction is known. But when a writer seeks to cast his speculations on the origin of colours, the phenomena of the rainbow, the action of the human eye and the like into the same form, he lays a trap for the ignorant and unwary, who may fail to distinguish the sudden emptiness of speculation from the proper process of thought.

This book, then, makes a re-appearance largely on account of its human interest, though it is a worthy addition to the historical optical literature already available in English. At a time when half the world appears ready to abandon sanity for catch-words and catch notions, anything which by attention to past follies would help mankind to detect its present ones seems like a draught of water in dry weather. The book would make a very suitable present for certain folk of the present day who write pontifically on vast problems with the aid of a little elementary chemistry and biology.

The publishers are to be congratulated on the attractive binding and excellent printing, which make this little book a pleasure to handle. L. C. M.

Quantitative Analysis

By Prof. Harold Simmons Booth and Prof. Vivian Richard Damerell. (International Chemical Series.) Pp. xi+246. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 15*s.*

IN "Quantitative Analysis" Profs. Booth and Damerell have produced a text-book avowedly for elementary students, but it covers a fairly wide field in its thirty-four chapters. The authors have set out with the intention of impressing upon beginners in analytical chemistry the vital necessity for extreme accuracy. Indeed the clue to the whole tenor of the book is to be found in the introductory chapter where the authors state that "one of the most important requirements for successful experimental work is to be honest with oneself. A high degree of personal integrity is absolutely necessary for lasting success in any science". To ensure that the student will thoroughly digest these truths, the authors have taken the greatest care to give very full details of procedure and explanations of experiments. In fact the wealth of advice, warning and instruction on laboratory technique which normally one learns only by long and often costly experience constitutes a novel feature of this text-book.

The actual experimental work described is confined to the determination of simple elements and radicals and has been selected not with the intention of being exhaustive but with the object of illustrating the basic principles of quantitative analysis. The general theory of gravimetric and volumetric analysis is simply but lucidly explained, and each chapter of the book contains a set of questions whereby the student can subject himself to a "self-examination".

This book can confidently be recommended to beginners in chemistry, and if the student assimilates both the chemical knowledge and the wealth of practical detail contained in the volume, he can scarcely fail to emerge as a most careful and highly qualified analyst.

Select Bibliography of South African Native Life and Problems

Compiled for the Inter-University Committee for African Studies, under the direction of I. Schapera. Pp. xii+250. (London: Oxford University Press, 1941.) 10*s.* 6*d.* net.

A "SELECT" biography tends to arouse a certain diffidence, not to say mistrust, in the manner of its reception; but when the material is drawn from a space of four centuries and a literature of the proportions and character of that relating to the natives of South Africa, much weeding is necessary if a practical value is to be secured for anyone who is not already in a great measure expert. The danger of bias, which may be, and indeed often is quite unconscious, has been eliminated in this South African bibliography by calling in the assistance of experts each to be responsible for the department of native studies in which he is an accepted authority, such as, for example, Prof. M. R. Drennan (physical anthropology), or Dr. A. J. Goodwin and Prof. C. van Riet Lowe (archæology) or the Rev. C. M. Doke (linguistics). The editor, whose ability to take an objective and scientific view of native problems has been abundantly demonstrated on many previous occasions, has been responsible not only for the section covering ethnography, both general and tribal, but also for that which deals with the status of the modern native population. It is perhaps unnecessary to comment on the fact that this last-named is the most considerable section in the bibliography, covering 93 pages as against ethnography, 72 pages. The very brief notes following entries, and indicating the scope and character of the item catalogued, will be found helpful and trustworthy by young students.

THE PHYSICAL CONDITION OF THE PLANETS*

BY SIR JAMES JEANS, O.M., F.R.S.

AS the power of telescopes increases the astronomical horizon for ever recedes, drawing many astronomical workers with it, but leaving a few to continue their labours in the older fields. I propose here to discuss some recent work in the oldest field of all—the planets.

The physical condition of a planet depends on many factors, the most important being its distance from the sun. For we have learned in recent years that each planet gives out just about as much light and heat as it receives from the sun, and no more. Thus the planets have but little heat of their own, and are hot only to the extent that they are warmed by the sun.

Yet distance from the sun is not everything. The earth and the moon are at the same distance from the sun, so that their average temperatures are approximately the same, but their physical conditions are widely different. The moon is a dead world in which we see mountains of volcanic rock rising from plains of lava and ash, while the earth teems with life. While the earth's temperature remains fairly steady through the alternations of day and night, that of the moon rushes from one extreme to the other. According to Pettit (1940) the moon's temperature can fall from 101° C. to − 117° C. during an eclipse. The change of temperature is far more violent than anything we experience on earth because the moon cannot, like the earth, draw on heat stored in its soil or atmosphere. It has a surface which is probably composed of lava and ash, which are almost perfect non-conductors of heat, and it has no appreciable atmosphere—an inevitable consequence of the smallness of its mass. The earth is strong enough gravitationally to retain the molecules of its atmosphere, while the moon is not.

Bodies of intermediate mass may retain the heavier kinds of molecules, while the lighter escape. For each planet we can calculate which gases are debarred, by their lightness, from appearing in the planet's atmosphere, although to know which actually do appear we must have recourse to observation.

The light by which we see a planet is simply sunlight which has passed twice through the planet's atmosphere—once in going in and once in coming out. These journeys may produce absorption bands in the spectrum of the light, and from these we can deduce the composition of the atmosphere, at least in part. There may also be some loss of light resulting from reflection at the planet's surface, for no substance reflects light perfectly. The proportion of light lost is different for different colours and by comparing the reflecting powers of the surface, colour by colour, with those of known terrestrial substances, it may be possible to identify the material of which the surface consists. Lyot has recently found that both the reflecting powers and the polarizing powers of the surfaces of Mercury, Mars and the moon are all identical with those of lava and pumice. Thus we can scarcely doubt that the surfaces of all these three bodies consist of the products of volcanic eruption in some form or other.

Let us now consider the various planets in turn, commencing with those nearest to the sun.

MERCURY

Nearest to the sun and so hottest of all the planets is Mercury. Just as the moon always presents the same face to the earth, so Mercury always presents the same face to the sun. Thus on one hemisphere of Mercury there is perpetual day—and a very hot day—while on the other hemisphere it is always night—and probably a very cold night. At the point directly under the sun, where it is always noon, the temperature is found to be about 650° F., a temperature at which lead and tin are both liquid.

It is still debatable whether Mercury possesses any considerable atmosphere or not. It is the least massive of all the planets, with only one twenty-second of the substance of the earth, and its power of retaining an atmosphere is small. Under present conditions it would retain oxygen and all heavier gases, but in the past, when it was presumably hotter even than now, all gases except the very heaviest may well have streamed off into space. On the whole its surface markings are so permanent and clear-cut as to suggest that no atmosphere in fact exists. Yet Schiaparelli noticed fifty years ago that some of the surface features were occasionally seen blurred, or even obscured, as though by some sort of cloud, and Antoniadi has recently (1929) confirmed and extended his observations. As the planet could not retain molecules of water vapour, and so must be completely arid, it has been suggested that the clouds may consist of particles of dust, possibly set free by falls of rock. Even so there must be some sort of atmosphere to save the dust particles from immediately falling back on to the surface of the planet.

---

* From a discourse delivered at the Royal Institution on March 25, 1941.

Venus

After Mercury comes Venus, the slightly smaller twin sister of the earth. The small differences of size and mass do not produce any appreciable difference in the atmosphere-retaining capacities of the two planets, and Venus, like the earth, can retain all gases, including hydrogen. Thus if we approach the problem merely in terms of the present state of the planets, we might reasonably expect Venus to exhibit an atmosphere similar to that of the earth, although perhaps somewhat smaller in amount.

Actually the two atmospheres are found to be very different. Something of this difference is suggested by the general appearance of Venus, which presents only a continuous cloud-like surface to our view. Gerasimovič has made a study of the brightness of this cloudy envelope and of the way in which it changes with the phases of the planet, and has shown (1937) that it cannot be gaseous but must consist of large scattering particles—probably products of condensation, like the ice crystals which form the cirrus clouds in our own atmosphere. We have no means of exploring whatever atmosphere there may be below this stratum of clouds, but the "upper atmosphere" above it can of course be examined spectroscopically.

Hydrogen, nitrogen and the inert monatomic gases cannot in any case be detected spectroscopically, but oxygen and most compounds can when present in reasonable amounts. A study of the upper atmosphere of Venus reveals no oxygen and no water vapour, but an abundance of carbon dioxide. This does not necessarily mean that there is no oxygen or water vapour at all, but it means there is very little. If all the oxygen in the earth's atmosphere were collected and spread out in a layer at atmospheric pressure, this layer would be considerably over a mile in thickness, while the carbon dioxide would form a similar layer only a very few feet thick; for the upper atmosphere of Venus, the corresponding thicknesses would be less than six feet of oxygen and more than two miles of carbon dioxide. In brief, carbon dioxide and oxygen change places. Further, St. John found that the total amount of water vapour in the upper atmosphere of Venus is certainly less than that above the highest clouds on earth.

Why should there be so great a difference in the atmospheres surrounding two such similar masses? And why in particular should the oxygen in the earth's atmosphere be free, while that in the atmosphere of Venus is combined with carbon?

As oxygen combines so eagerly with other substances, we might reasonably have expected to find but little free oxygen left in either atmosphere. It has often been suggested that the free oxygen in the earth's atmosphere may be a direct result of the vegetation on the earth's surface; that as this breaks up compounds of oxygen, carbon dioxide in particular, it sets oxygen free in the air. But this can scarcely be the whole story, since primitive life must have required, and found, some free oxygen when it first arrived on earth. Tamman has suggested (1924) that, while the earth was still hot and its solid crust not yet formed, a considerable amount of free oxygen would be produced by the thermal dissociation of water vapour. He calculated that if the whole of the water, ice and snow at present on earth were restored to the temperatures of this epoch, there would be enough water molecules dissociated to provide all the free oxygen at present residing in the earth's atmosphere. The free hydrogen would not, as at present, be retained but would stream off into space. No doubt some of the free oxygen would in due course combine with the solidifying rock of the earth's crust, but vegetation would afterwards come into being to restore the balance. So long as we can postulate both water vapour and vegetation, there will be no great difficulty in accounting for the presence of free oxygen.

If so, there may be no free oxygen on Venus either because there is not enough vegetation, or because there has not been enough water vapour.

As regards the first alternative, we may imagine life to have come to earth as the result of some unusual accident, some rare coincidence, or some special creation, if we prefer. If the corresponding event did not occur on Venus, the whole situation is explained; there is no oxygen, because there is no vegetation. Or it may be that Venus has never cooled down sufficiently for life to appear. There is enough carbon dioxide in the earth's atmosphere to exert a powerful blanketing effect, checking the outward flow of radiation and so keeping the earth considerably warmer than it would otherwise be. The thousand-fold thicker layer on Venus must form a far more potent blanket, and estimates of the temperature of the lower atmosphere of Venus range from about 80° C. to 130° C. Atmospheric pressure on Venus may well be somewhat less than on earth, so that any water that there may be there is likely to exist in the form of steam. If so, Venus must be highly unsuited to life now and must have been even more so in the remote past.

The other possibility, which has been urged by Wildt (1940), is that Venus has always been deficient in water. As Venus and the earth were almost certainly formed out of the same store of matter—the outer layers of the sun—they would probably start with equal amounts of water vapour. But at a later stage, the smaller mass and higher temperature of Venus may have permitted molecules of water vapour to escape from the atmosphere of Venus, while they were still retained by the earth. If so, any small amount of oxygen set free by thermal dissociation might well be seized by the solidifying rocks, and vegetation could not then come, since there would be insufficient oxygen for it to breathe.

There would also be insufficient oxygen or ozone to screen the atmosphere from the ultra-violet rays of the sun. Wildt accordingly imagines photochemical action occurring on an extensive scale, resulting first in the dissociation of carbon dioxide and whatever water vapour there might be, and afterwards in the formation of formaldehyde (CH_2O) and free oxygen. The free oxygen would continue to combine with the rocks, but the formaldehyde might be expected to remain in the atmosphere. Wildt has accordingly examined Venus spectroscopically for formaldehyde but found none (1940). He states that dry formaldehyde is stable at temperatures higher than about 80° C.; at lower temperatures it polymerizes into a white solid of high but unknown molecular weight. Trautz and Ufer found that the injection of a small amount of water vapour into perfectly dry formaldehyde gas produced masses of dense white cloud. Wildt suggests that the clouds we see on Venus are similar, and so consist of solid particles of hydrates of formaldehyde polymers. According to Auerbach, depolymerization into simple CH_2O molecules does not occur until the temperature exceeds 200° C., a fact which fully explains the failure of Wildt's spectroscopic search for formaldehyde. Wildt thinks it possible that Venus's atmosphere may be entirely depleted of water vapour and its surface covered with particles like those which form its clouds—a sort of formaldehyde snow.

In whatever way it may have originated, we can form a fairly accurate picture of the present state of Venus—a hot dry surface, devoid of vegetation and probably of all life such as we know on earth, surrounded by an atmosphere in which there floats a continuous layer of opaque clouds, which are probably similar in their physical, although not in their chemical, constitution to the cirrus clouds of our own atmosphere.

MARS

Crossing the earth's orbit, we come to planets which are colder than our own. Mars, which comes first, is not enormously colder, its average temperature being about −40° C. Actual temperatures are fairly widely spread about this average, those observed ranging from + 10° C. (summer afternoon on Martian equator) to − 70° C. (polar regions in winter).

The fact that the temperatures are not more widely spread suggests that Mars must be surrounded by a very substantial atmosphere, and observation confirms that this is so. W. H. Wright of Lick Observatory photographed the planet in infra-red light, which penetrates any atmosphere there may be and so photographs the solid body of the planet, and also with ultra-violet light, which has very little penetrating power and so photographs the surface not of the planet but of its atmosphere. He found that the ultra-violet image was measurably larger than the infra-red image, and thus obtained clear proof that Mars has an atmosphere, which he estimated to be from 50 to 60 miles high.

We still know very little of the constitution of this atmosphere. Spectroscopic analysis so far finds no definite evidence of either oxygen, carbon dioxide or water vapour. The rather insensitive test for water vapour merely shows that there cannot be a tenth as much water vapour per square yard as in our own atmosphere.

The two poles of Mars are surrounded by white areas, generally known as "polar ice caps", which diminish in size in warmer weather and disappear almost entirely in summer. They were so named from analogy with the ice-caps on our own planet, but their true nature is probably revealed by the photographs of W. H. Wright, already mentioned. The caps are found to show very clearly in ultra-violet light, but are almost invisible in infra-red light. The only possible inference would seem to be that the caps are merely atmospheric phenomena. They may well consist of clouds of small solid particles, like the clouds which cover the surface of Venus.

The want of oxygen and carbon dioxide in the atmosphere of Mars suggests that this planet also resembles Venus in not possessing vegetation of the kind we know on earth. There are, nevertheless, certain dark areas on the surface of the planet which vary unmistakably, both in colour and extent, as the seasons change. In the past these variations were frequently adduced as evidence of the presence of growing vegetation, but in the light of our present knowledge it seems more reasonable to assign meteorological causes to them—possibly the falling of rain on a desert of volcanic rock or ash.

Thus the general picture we form of Mars is that of a larger and colder moon, which, because of its somewhat greater size and mass, has retained something of an atmosphere, and may still have rains, cloud and fog to vary its appearance.

THE OUTER PLANETS

Mars is the last planet on which a solid surface can be seen. Apart from Pluto, about which we know almost nothing, all the planets beyond Mars are much more massive than the earth, and as they are also much colder we should expect them to retain deep atmospheres, as detailed studies make it clear they do.

Wildt estimates that the atmosphere of Jupiter has a depth of 6,000 miles, with an average density of 0·78. For Saturn the figures are 16,000 miles and 0·41, so that the atmosphere occupies more than four-fifths of the whole volume of the planet.

The greater part of both atmospheres will be at a pressure of more than a million terrestrial atmospheres. Under such pressures, no known substance remains gaseous, so that what we have called the "atmospheres" of these planets must mainly consist of solids and liquids. Also, under such pressures, most substances become denser than water; the principal exceptions are hydrogen, helium, methane (CH_4), ethane (C_2H_6) and ammonia (NH_3). The low density of the "atmospheres" of Jupiter and Saturn suggests that they must consist largely of these substances. Hydrogen and helium, which it is not possible to detect by spectroscopic means, probably figure largely in both atmospheres, because they are abundant in the outer layers of the sun; both planets have ample gravitational power to retain them with ease, even at very high temperatures. The only substances which spectroscopic examination discloses are methane, which occurs in profusion, and ammonia, which is not found to occur in any great quantity. It is remarkable that these two gases account for absolutely the whole of the absorption of light observed in the atmospheres of Jupiter and Saturn. If other constituents are present, they are either in amounts too small to be observed or else, like hydrogen and helium, make no spectroscopic impression on light passing through them.

Still farther away from the sun come Uranus and Neptune, which prove to be merely colder miniatures of Jupiter and Saturn. The observed temperature of Jupiter is − 138° C. and of Saturn − 153° C.; the temperature of Uranus is certainly lower than − 183° C. and that of Neptune probably lower still, perhaps about − 210° C.

In their general structure the two planets are clearly similar to Jupiter and Saturn; the spectra of their atmospheres are also similar, both showing a great abundance of methane, although ammonia has not yet been detected—possibly the extreme cold has frozen it out.

We can now try to form a physical picture of the system of planets as a whole. Leaving out Pluto, because we know nothing about it, and reserving Venus and the earth for later discussion, we see a sequence of planets—Mercury, Mars, Jupiter, Saturn, Uranus and Neptune—in which the physical conditions vary continuously as we pass along the sequence. We find heat giving place to cold, absolute aridity to an abundance of water or ice, while the atmospheres increase in depth and extent and hydrogen probably increases from nil to a large amount, existing in the form either of free hydrogen or of its compounds, especially methane.

The reason why the twin planets, Venus and the earth, do not altogether fit into this sequence is in part because they are more massive than their immediate neighbours Mercury and Mars, and so retain more atmosphere. After allowing for this, Venus fits into the sequence fairly well, but the earth still remains anomalous in having so much oxygen and water vapour in its atmosphere. This is probably a consequence of its clothing of vegetation; life has come to the earth and thrown it out of its place in the regular sequence.

Not long ago it used to be thought that the sun was continually cooling and the planets with it. What the earth now is, it used to be said, Mars must have been in the not very remote past and Venus will be in the not very remote future. If the earth is the only planet on which life now exists, Mars may nevertheless be the planet of spent life and Venus the planet of life yet to come. Our recently acquired knowledge of stellar structure and stellar evolution requires a substantial modification of this view. The sun obtains its energy from subatomic re-arrangement of its substance, light elements combining to form heavy ones, but so long as the supply of light elements does not give out entirely, the effect of these chemical changes on the sun's mechanical structure and on its outpouring of energy is extremely slight. Thus Mars must have had its present chilly temperature since those remote days when it was still warmed by the heat it had brought from the sun, and Venus will retain its present heat until the sun's supply of light elements becomes used up and it collapses into a cooler and smaller "white dwarf". This being so, the idea that life can progress along the planetary sequence is probably illusory. The earth is the planet of life because it is at the right distance from the sun, but there is no justification for thinking either that life of the kind we know on earth once existed on Mars or that it will in due course appear on Venus; these planets are at the wrong distance from the sun.

INDUSTRIES OF THE CROMER FOREST BED

BY J. REID MOIR, F.R.S.

CLEMENT REID, in his well-known description of the deposits of the Cromer Forest Bed in Norfolk, states[1]: "Both the fauna and flora, leaving out the large mammals and other extinct forms, are curiously like that of the 'Broad District' of Norfolk at the present day; and this, like the rest of the evidence, points to a wide alluvial plain with lakes and sluggish streams, bounded on the west by a slightly higher sandy country covered with fir-forests and distant from any hills." The climate of this pleasant hunting country, now obliterated by the North Sea and great thicknesses of glacial deposits, was evidently genial, and we may suppose very suitable for the primitive people inhabiting the region in those remote days. It is, in fact, somewhat difficult to imagine a terrain, rich in wood, flint of first-class quality, and big game, more suitable for the successful activities of the men of the Old Stone Age, and researches carried out in recent years have demonstrated that a succession of races of these people lived in the valley of the ancient Rhine.

Some years ago, I was able to establish that five different periods of human flaking on flints were present in the Suffolk Bone Bed beneath the Red Crag of Suffolk[2], thus extending very considerably the duration of man's existence in the Pliocene epoch. Now I am able to announce that no less than *seven* periods of artificial flaking of flints are present in the basal layer of the Cromer Forest Bed. This, if my conclusions are found to be accurate, means that the duration of man's existence in the Early Pleistocene epoch must also be extended considerably.

The manner in which it is possible to distinguish different periods of flaking upon flints is quite simple, and in most cases irrefutable. A flint implement in the course of time—almost certainly prolonged—has, under natural conditions, become patinated and stained. Its flake scars exhibit a very definite coloration—for example, a dark mahogany brown—and at one or more places this flaking has been cut into by later fractures and these may be of a white, blue or other colour. When, moreover, it is found that the deposit under examination contains assemblages of flint implements differing from each other in their morphological details, and exhibiting patinations comparable with those observed upon the re-flaked specimens, it is evident that we are dealing with artefacts of different ages, made by a succession of races of prehistoric people. The various groups of implements discovered in the Suffolk Bone Bed at one time lay either on, or in, a pre-Crag land surface which was broken up and redeposited by marine action, and in the case of the basal layer of the Cromer Forest Bed, now to be considered, a comparable explanation is postulated.

At certain sites along the north-east coast of Norfolk, this basal layer is exposed either at the foot of the cliffs or upon the foreshore at low tide. The deposit is a very hard ferruginous bed composed of sand, large numbers of flints, and in places marine shells and the remains of terrestrial mammals. Where the bed is present upon the foreshore, it is gradually broken up by wave-action, which washes away the sand matrix and leaves the harder constituents—flints, bones, etc.—upon the underlying surface of chalk.

It is from the large 'sporads' of flints thus formed that considerable numbers of artefacts have been recovered, but many other comparable specimens have been found in the basal layer where it is *in situ* and undisturbed. The seven groups of humanly flaked flints discovered in the basal layer of the Cromer Forest Bed may be described, briefly, as follows:

(1) Specimens exhibiting either a purplish colour with chestnut brown areas, or the well-known 'blacklead' patination. The predominant form is a coarsely flaked hand-axe. Rostrocarinates occur and many striking examples of transitional rostrate hand-axes. There are also racloirs, choppers, scrapers, and points. The specimens tend to be massive in size and are often severely striated and abraded.

(2) Reddish-brown specimens composed largely of flakes of considerable size showing prominent bulks of percussion, and when present, flat striking platforms. A few large core pieces and some borers and scrapers. Flints very seldom exhibit striations, or the amount of abrasion seen on the specimens of Group 1. Hand-axes and rostrocarinates are very rare.

(3) Ochreous-yellow specimens almost entirely composed of flakes generally less in size than those of Group 2 and exhibiting smaller bulbs of percussion. A few racloirs and scrapers. Striation negligible and little abraded.

(4) A small series of greenish-yellow specimens comprising steep-faced scrapers and points. Flakes very rare. Flints exhibit no striations but some signs of rolling.

(5) Specimens of a cream or white colour.

Numerous flakes usually exhibiting small bulbs of percussion. Some fine racloirs, broad scrapers and points. One racloir shows two adjacent bulbs of percussion, and the cutting edge formed by 'resolved' flaking. Some striations but little abrasion.

(6) Blue flakes, some showing signs of use, tending to be large with some well-formed bulbs of percussion. No striations or abrasion.

(7) Black, unchanged flakes, some showing signs of use, and smallish bulbs of percussion. No striations or abrasion.

The above groups are arranged in what appears to be their respective ages as shown by the re-flaked specimens and indicate that in Early Pleistocene times an industry rich in primitive hand-axes, rostrocarinates and transitional forms was followed by a succession of what must be regarded, on the evidence at present available, as flake industries in which core implements are, to all intents and purposes, absent. The presence of hand-axes in Group 1 makes it advisable to refer all these industries to early Palæolithic times, while those in the more ancient Bone Bed of Suffolk, which differ very markedly in many respects from the Forest Bed artefacts, and in which hand-axes are of an exceeding rarity, are to be relegated to the Eolithic period.

In the Estuarine Bed above the basal layer of the Cromer Forest Bed a few artefacts have been found, chiefly by Mr. J. E. Sainty, who has given me invaluable help in my investigations. These specimens are of somewhat primitive types and their flake-scars exhibit, usually, a shiny black coloration, and are derivatives in the Estuarine Bed. The Upper Freshwater Bed, above the latter accumulation, has, so far, yielded no recognizable flint artefacts.[2] A representative series of the Cromer Forest Bed industries has been arranged in Ipswich Museum. The research was carried out under the auspices of the Royal Society and the Percy Sladen Memorial Fund.

CHEMICAL SUBSTITUTES FOR DIETARY PROTEIN

By R. BENESCH,
DEPARTMENT OF AGRICULTURE, UNIVERSITY OF LEEDS

INTRODUCTION

UNDER present war-time conditions the protein supply of the nation is of paramount importance. The problem of finding substitutes for dietary protein, therefore, in the form of simple nitrogenous compounds of a non-protein nature, capable of industrial synthesis, opens up new possibilities in war-time economy. The aim of this discussion is to show that this problem has reached a practical stage.

Experiments have been carried out over a period of years in various countries, investigating the effect of urea, ammonium acetate, ammonium bicarbonate, glycine, asparagine, succinamide, and other similar substances. These experiments were designed to ascertain the result of this 'amide' substitution on :

(*A*) Dairy cattle and goats (for milk production).
(*B*) Heifers, bullocks, etc. (for meat production).
(*C*) Sheep (for meat and wool production).
(*D*) Humans.

The above were all practical feeding experiments. Another series of experiments attempted to discover the mechanism by which protein substitution is brought about.

(*A*) DAIRY CATTLE AND GOATS (FOR MILK PRODUCTION)

Ziemer and Ehrenberg fed goats and milk cows with ammonium bicarbonate in conjunction with acid sugar beet slices, sour whey, and silage (that is, with the ammonium salts of the organic acids present in these feeding stuffs), replacing protein nitrogen by equivalent amounts of ammonia. Extra starch was given to make up the calorific value of the ammonium bicarbonate.

With goats ammonium bicarbonate was able to replace 50 per cent of the food protein for milk production. With milk cows up to 76 per cent of the production protein could be replaced by equivalent amounts of ammonium bicarbonate, which, whilst not reaching completely the effect of good oil-cake food, proved a satisfactory substitute, provided that it was fed in conjunction with a suitable commercial or home-grown starch supplement. However, the extent to which ammonium bicarbonate was utilized was influenced largely by the individuality of the animals ; cows with more than three gallons milk yield not responding very well to the ammonia feeding. The composition of the milk remained perfectly normal in the ammonia-fed animals.

Similar experiments with urea and glycine showed that, in terms of milk production (4 per cent fat content), the efficiency of urea and glycine was about 40 per cent and 30 per cent respectively that of the oil-cake.

Richter and Herbst, also working with urea and glycine, obtained a reduction in milk yield when the replacement of production protein by 'amides' reached 50 per cent.

Eventually mass experiments were conducted by the German *Forschungsdienst*, according to a common experimental plan, in which the protein demand for about two gallons of milk was covered by 'amides'. In general, the 'amides' were found to possess half the efficiency of protein. Therefore a *Wertigkeit* (complementary value) of 50 was allotted to the urea nitrogen. These results led finally to the commercial manufacture of the amide oil-cake mixed concentrate (*Amidoelkuchenmischfutter*) by the German I.G.

(*B*) CATTLE (FOR MEAT PRODUCTION)

In experiments by Fingerling *et al.*, two nine-months-old bullocks had the gluten of their production ration replaced by equivalent amounts of urea, with the result that nearly the same nitrogen-balance was obtained as before. The relative retentions of gluten and urea nitrogen in the total protein, expressed as a percentage of the total nitrogen absorbed, were calculated as 61·7 per cent and 55·8 per cent respectively. When during a subsequent period only the minimum maintenance protein was fed, a sharp drop in the nitrogen retention occurred, proving that the amount of nitrogen retained in the urea period could not have been due to the maintenance protein. The authors, therefore, conclude that the nitrogen of urea can be utilized within fairly wide limits by the growing animal. Hence, they advocate the introduction of urea as a protein substitute into agricultural practice.

Bartlett and Cotton at Reading tested the effect of urea on dairy heifers 7–12 months old by replacing one-third of the protein ration with the 'amide'. Body measurements, handling properties, fatness etc., were observed. No significant differences were found between the 'amide' fed and protein fed animals. With regard to live-weight increases the conclusion was reached that animals receiving nitrogen over and above the low protein level in the form of protein showed better live-weight gains than those receiving the same quantity in the form of urea. The differences, however, were statistically not significant.

In a Rhodesian experiment, by Murray and Romyn, the live-weight increases of Red Poll heifers over a period of ninety-three days was found to be approximately the same by feeding equivalent amounts of urea as by feeding peanut cake.

In America, Hart, Deobald and Bohstedt experimented with four calves, the first receiving a low protein ration, and the others getting the same feed plus urea in the second, ammonium bicarbonate in the third, and casein in the case of the fourth calf. The live-weight gains were 65, 105, 110 and 126 lb. respectively, again confirming a considerable utilization of 'amides'.

(*C*) SHEEP (FOR MEAT AND WOOL PRODUCTION)

Among the more recent experiments in this field there are the investigations with growing lambs by Nehring and Schramm, who replaced one-third of the total nitrogen by urea, glycine and ammonium acetate respectively. Whilst the nitrogen-balances were negative in the basal and low protein periods, they became positive in the 'amide' periods, reaching a maximum with ammonium acetate.

In this connexion mention should be made of various criticisms advanced by some workers against these positive results. For example, the question of excretion of ammonia via the lungs and intestinal gases has been raised. This was investigated by Nehring and Schramm, by Scheunert and by Sauer, with absolutely negative results. Further, the possibility of a mere *flooding* of the blood and organs by the 'amides' has been suggested. This criticism was based on increases in 'rest' nitrogen in the blood of 'amide' fed animals. But whilst these increases amounted to one or two grams over a period of *several weeks*, there was a *daily* nitrogen retention of 2–3 gm.

Nehring and Schramm also tested the effect of dried beet slices plus urea, and of molassed bran plus urea, as part of the previously mentioned German mass experiments. The conclusions were :

(1) The experiments with the two preparations showed that up to 200 gm. of urea per day could be fed without any ill-effects.

(2) The digestibility of the two feeding stuffs was very high, and apart from the urea it was 82 per cent and 85 per cent respectively.

(3) The feeding of the two 'amide' preparations caused an improvement in the nitrogen-balance. As compared with the basal period with hay there was a retention of 2–3 gm. of N. more in the slices, and 1 gm. more in the bran.

Very similar results were obtained by Mangold and Stotz, who experimented with linseed cake plus urea, and with potato flakes plus urea. The percentage of urea in both preparations was about 15 per cent.

Further, Liliencron, feeding glycine to lambs for 150 days, obtained very satisfactory results. Similarly, Kirsch and Sauer, studying the effect of different 'amides' on growing sheep, when 20–30 per cent of the nitrogen was replaced, found no differences between the normal and urea groups with regard to live-weight gain and wool production.

The most conclusive experiment of all, however, was reported by Nehring and Schramm in 1939. Four groups of animals were used. In one, protein was fed in adequate amounts (normal group), in the second, one-third of the crude protein or one-half of the digestible crude protein was left out (deficient group), and in the third and fourth groups this one-third was replaced by equivalent amounts of urea and glycine (amide groups).

This is the first experiment in which both nitrogen-balances and live-weight gains were recorded and related to each other by recalculating the nitrogen retention into live-weight gains with very good agreement. The sulphur-balances, following closely the result of the nitrogen-balances, confirmed the anabolic utilization of the nitrogen retained.

The results can be summarized in the accompanying table :

	Groups			
	Normal	Deficient	Urea	Glycine
N retention in gm./day ..	4·87	3·13	4·86	4·90
S ,, ,, ,, ..	0·519	0·342	0·379	0·432
Daily live-weight gain in gm.	102·5	75·4	93·0	101·0
Live-weight gain minus wool increase in gm./day ..	93·2	63·8	82·8	89·6
Live-weight gain calculated from N retention minus wool N in gm./day	100·1	53·8	97·2	99·4

These results of the nitrogen investigations, supported by the determination of the sulphur-balance and related to the results of live-weight gains, are regarded as proof that 'amide'-like substances like urea and glycine can be utilized in the growing ruminant under certain conditions in place of protein for the production of new body substance.

Experiments, which gave negative results, but which were in the author's opinion invalidated by various flaws, have been omitted for the sake of brevity.

(*D*) Humans

Whilst in the ruminant a definite retention of non-protein nitrogenous compounds has been established, the question of a retention of non-protein nitrogen in the human is completely unsettled, and although results hitherto obtained are contradictory and inconclusive, they seem to point to a negative answer. This agrees with the evidence on the mechanism of non-protein nitrogen utilization, put forward in the next section.

Influence of Micro-organisms

As far back as 1843 the view was expressed that Infusoria might have a special nutritional significance. Later, Pasteur and A. Mayer succeeded in forming protein of micro-organisms in yeast moulds from ammonia. These results were confirmed by M. Mueller with asparagine and ammonium hydrogen tartrate, by showing that rumen bacteria prefer these substances to protein for anabolic purposes, thereby producing considerable quantities of protein. Zuntz interpreted these results by assuming that 'amides' could be used by the ruminant by way of assimilation by bacteria in the rumen, and their subsequent digestion in the truly enzymatic digestive tract (Zuntz's bacteria hypothesis).

In 1920, on the basis of extensive experiments, Voeltz concluded that urea can assume the role of food protein in the metabolism of the ruminant, whereby urea is first built up into bacterial protein in the digestive tract, 80–90 per cent of which is afterwards absorbed from the intestines.

The first quantitative data on the problem were supplied by Schwarz, who found that the nitrogen of the bacteria and infusoria accounted for 11·7 and 20 per cent respectively of the total nitrogen content of the rumen. He calculated the weight of micro-organisms per 100 kgm. rumen content as 2·79 kgm., which contains 41 gm. of nitrogen, corresponding to 256 *gm. of protein*, 80–90 per cent of which can be utilized, according to Voeltz. The protein requirement of the ruminant, however, is put at 0·6 lb. per 1,000 lb. live-weight, corresponding to 272 *gm. of protein*. There is, therefore, stored in the micro-organisms a sufficient amount of protein for covering the protein requirement of the animal. Unfortunately, the crucial point, whether there is an increase in the micro-organic nitrogen of the rumen during 'amide' feeding has never, to my knowledge, been *directly* investigated.

With regard to the question of the subsequent digestion of the bacterial protein formed in the rumen, Bruner showed that a glycerol extract of pancreas, containing trypsin, dissolves Gram-negative, but not Gram-positive bacteria. Pepsin, amylase and lipase show no distinct effects on the two groups of bacteria. Therefore it seems possible that not only does the bacterial synthesis in the rumen depend on variable conditions, but that also the bacterial protein thus formed can be digested to a variable degree by the digestive enzymes.

Research into the creation of favourable conditions for protein synthesis is, therefore, *imperative*. It is obviously necessary to influence the activities of the rumen micro-organisms, so that within natural limits protein bricks of all necessary kinds in the right proportions are manufactured in order to ensure the synthesis of a corresponding amount of milk, meat, wool, etc. This is clearly linked up with the whole question of protein make-up, biological values, etc.

Very interesting are the results of Klein and his co-workers, who on the basis of the results of metabolism experiments and from the mycological and metabolic changes of the rumen paste and of the fæces, concluded, that in certain protein-deficient combinations in the rumen, protein can be synthesized from the nitrogenous fractions of 'molasses-amides'.

A further contribution in this connexion are the experiments by Lenkeit and Becker on the fate of the urea of 'amide-flakes' in the rumen. Two series of experiments were carried out, one *in vivo* and one *in vitro*. In the former, the decomposition of urea into ammonia and carbon dioxide was instantaneous, but in the latter, working with rumen extracts, it could be followed analytically. There was a progressive decrease of urea nitrogen and increase of ammonia nitrogen, leading to the complete decomposition of the urea after twenty-four hours. *But* 10–20 *per cent of the original urea nitrogen does not appear in the form of ammonia.* The explanation of this fact probably lies in the fixation of ammonia nitrogen in the metabolism of the animal or in the micro-organisms present.

CONCLUSION

This whole problem of 'amide' substitution is, therefore, a very important one, especially in present war-time conditions, although it might even be considered in peace-time as a means of reducing the cost of the most expensive constituent of the production ration, namely, protein.

Under war-time conditions it appears essential to be able to feed for production purposes with substances which can be produced synthetically at home at a reasonable price. These 'amides' have, however, to be fed in conjunction with suitable foods. This problem has already been largely solved in Germany, where four preparations are manufactured industrially:

(1) Dried beet slices with urea solution.
(2) Molassed bran with addition of urea.
(3) Linseed meal with urea.
(4) Potato flakes with urea.

In this connexion the following suggestions are offered:

(1) We in Great Britain could make immediate use of all the results of the German experiments, without going through the tedious processes through which they have gone.

(2) Although it took a war to impress the importance of silage-making upon the British farmer, in the case of 'amide' substitutes he would just receive the ready-made feeding-stuffs (like any other cake) from industry, and therefore the inertia of the farmer would be more easily overcome than in the case of silage, which he has to produce on his own farm.

(3) Ammonium salts can be fed in conjunction with silage, a fact very significant in view of the introduction of silos on to many British farms.

(4) It should be the task of the industrial chemist to find cheap methods of synthesizing the various 'amides'.

(5) Bacteriological research should ascertain the optimum conditions for protein synthesis in the rumen, as well as find the particular groups of bacteria best suited for the purpose. The synthetic feeding stuffs could then be *inoculated* with these strains, and thus it might be found possible to feed even more concentrated 'amide' foods than the Germans were able to use. That this idea is a very practicable one is shown by the opinion, expressed by many workers, that the bacterial activities in the rumen occur first and foremost under the influence of bacteria *ingested from the outside.*

(6) The enormous saving in shipping space which could be attained by the use of synthetic 'amide' foods should be strongly emphasized. Even assuming the complementary value of 'amides' to be only 50 per cent, a 50 per cent reduction in shipping space would be effected, since, instead of 100 parts of cake, 50 parts of 'amides' plus 50 parts of cake could be fed.

We have, therefore, in this problem a unique opportunity for the industrial chemist, the theoretical scientist, that is, biochemist and bacteriologist *and* the practical agriculturist, that is, stock-feeder and dairyman, to co-operate in the solution of a problem which is vital for the feeding of the nation, and therefore for the successful prosecution of the War.

OBITUARIES

Sir Frederick Banting, K.B.E., F.R.S.

MAJOR SIR FREDERICK BANTING died in Newfoundland on February 21. He was on his way to England "on a mission", as the Prime Minister of Canada has said, "of high national and scientific importance". The pilot of the American bomber in which Banting was flying attempted a forced landing after the development of trouble with the engines, and in the resulting crash Banting and two of the crew members received injuries which proved to be fatal. In his death the Empire has lost one of its most distinguished citizens and the human race one of the greatest benefactors of our time. Canada could ill afford to lose him. There was no more important figure than his in our general war effort.

Frederick Grant Banting was born in Alliston, Ontario, on November 14, 1891, of Irish and Scottish ancestry. After receiving his preliminary education in the public and high schools of Alliston, he began his medical course at the University of Toronto in 1912. He enlisted as a private soldier in 1915, but was ordered back to finish his university training. He completed his medical course in 1916 and immediately joined the Canadian Army Medical Corps. He proceeded to France and was wounded at Cambrai in September 1918. He received the Military Cross for valorous conduct during the Cambrai engagement.

In 1919 and 1920 Banting served as resident surgeon in the Hospital for Sick Children, Toronto. He then moved to London, Ontario, where he began to build up a practice. He spent part of his time as research assistant in the Department of Physiology of the University of Western Ontario. In the course of the preparation of a lecture on diabetes the idea which was to change the course of his life presented itself. Banting was determined that this idea should receive an adequate trial and on the advice of his associates interviewed Prof. J. J. R. Macleod in the University of Toronto. In his lectures on carbohydrate metabolism to his senior students during the academic session of 1920–21, Prof. Macleod outlined Banting's hypothesis, and while he fully appreciated the difficulties of such an investigation he did feel that adequate opportunities for a trial should be provided. The work was begun on May 16, 1921, in collaboration with myself. The actual results of the experiments are recorded in our notebooks and in our published articles ; but the memories of that intimate association during the spring, summer and autumn in 1921 are now difficult to describe. Banting was always happiest when the investigations demanded great mental and physical activity. In these circumstances the days were always too short and continuous observations for several days and nights were not infrequently made. There is no doubt that his dogged perseverance was a highly important factor in the success which attended the insulin investigations. Banting always retained that freshness of mind and modesty of bearing which characterized him when he was conducting his first researches. These qualities were blended with an iron determination and an exceptional measure of courage to produce a character which will be vividly remembered by all who knew him intimately.

After the discovery of insulin a great many pathways were open to Banting. He would have had no difficulty in becoming a successful diabetic specialist. He often mentioned the possibility that he would return to the practice of surgery. Many institutions placed their facilities at his disposal, but he was steadfast in his determination to remain in Canada and probably always intended to spend at least a part of his time in medical research. His active interest in the clinical applications of insulin was shortlived and he soon turned his attention whole-heartedly to physiological problems. He did excellent work while investigating the functions of the suprarenal cortex and in several other intensive studies. It is greatly to his credit that after the initial dramatic discovery he was able to content himself for prolonged periods with programmes of research which promised no immediate results of practical value.

Banting directed and actively participated in cancer research for many years, and he was very proud when the experts in this field stated that his group was making a substantial contribution. Nothing gave him greater pleasure than to spend his time in experimental work which demanded his full attention. He often regretted that he could not spend more of his time in this way.

Banting was probably one of the few medical men of science in the Empire who actually made preparations for war researches well before the outbreak of hostilities. He was almost entirely responsible for the inception and organization of the researches in aviation medicine which have been carried out under the auspices of the National Research Council of Canada. His energy and enthusiasm in this work knew no bounds. He demonstrated an organizing ability which astonished even his intimate friends. Canada's war activities along medical lines owe much to the stimulus which it has received from Banting's efforts. It is probable that his last work will rank among his greatest achievements.

Banting appreciated deeply the honours which were showered upon him, but nothing diverted him from the development of medical research in Canada. He thoroughly enjoyed vacations, during which he was able to give scope to his talent for transferring the beauties of the Canadian landscape to canvas, but these periods away from his laboratory were always short. He had gathered around him a group of active young workers whose efforts have already been rewarded by a considerable measure of success. Their chief was keenly aware of all the difficulties in the problems which he asked them to attack. He was inclined to be intolerant of those who favoured the leisurely approach and felt that a research worker should throw himself heart and soul into the struggle. His philosophy of life was that men are prevented from reaching their goal by their inability to "think and work hard enough and long enough".

During the last few years Banting had the opportunity of becoming intimately acquainted with most of the active workers in medical research in Canada and of studying their methods in their laboratories. His passionate devotion to the open-minded experimental approach to medical problems and his ability to communicate his enthusiasm to other people will be dominant factors in the development of this work in Canada for many years to come.

C. H. BEST.

Dr. J. Rendel Harris

WE regret to record the death of Dr. J. Rendel Harris, Biblical scholar, archæologist and orientalist, which took place at Selly Oak, Birmingham, on March 1 at the age of eighty-eight years.

James Rendel Harris was born in 1852 and educated at Weymouth Grammar School and Clare College, Cambridge, of which he became a fellow and lecturer after he had graduated as Third Wrangler in 1874. Although a mathematician—he served as moderator and examiner in the Mathematical Tripos—he turned to Biblical and patristic studies, to which he became ardently devoted, rapidly attaining an outstanding position in textual criticism. In 1882 he left Cambridge for the United States, where he remained for some years, holding the chair of New Testament Greek in Johns Hopkins University, Baltimore, and later that of Biblical languages at Haverford College, Pennsylvania.

In 1893, Harris returned to Cambridge, and for ten years he was University lecturer in palæography, travelling extensively the while in the East in search of manuscripts. His success in this field of research, combined with his profound scholarship, bore fruit in notable and lasting contributions to Biblical and Syriac studies. After a brief tenure of the professorial chair of theology at Leyden he became director of studies at the Settlement for Social and Religious Studies of the Society of Friends at Woodbrooke, near Birmingham.

At Woodbrooke, Harris continued his studies in Syriac, but turned in an increasing degree to research in anthropology and folk-lore, devoting himself more particularly to the examination of early Mediterranean cults and their relation to forms of popular and other beliefs in the Christian Church. In "The Cult of the Heavenly Twins" (1906) and "Boanerges" (1913), the former dealing with the legend of the Dioscuri, he showed, with a wealth of comparative illustration and much detached evidence, that many of the pairs of saints in the Christian calendar could be traced back to a connexion with a cult of the Great Twin Brethren. Further studies on analogous lines, issued separately, dealt with the cults of Dionysos, Apollo, Artemis and Aphrodite; two major works were "The Ascent of Olympus" and "Picus who is also Zeus".

Prof. Richard Bär

SWISS physics and Swiss physicists suffered a severe loss, when, on December 13, 1940, Prof. Richard Bär died in his home in Zurich (where he had been professor of physics in the University)—a home whose hospitality many of his colleagues from all parts of the world will remember, having passed the friendly town on pleasure trips to the Alps and having met there not only with the friendliest reception but with one of the most distinguished of Switzerland's learned and literary circles.

Only now, after his premature death, it has been known how lavishly R. Bär had used his wealth to alleviate the lot of the distressed—in the first place of those uprooted by any kind of spiritual intolerance. He had a sort of shyness of giving and would, ostensibly, deny his assistance but send the applicants to a friend of his, pretending that his friend was in charge of an ample assistance fund (which he actually was, but the fund was supplied by R. Bär). I am told that the reception of about thirty displaced scholars at Istanbul was mainly due to R. Bär's initiative, who seized the prospect as soon as it turned up and arranged matters by a personal visit to Istanbul, to which he invited two influential friends.

To most physicists R. Bär is best known by his vigorous and fully successful attempt to disprove by clear and decisive experiments the doubts which F. Ehrenhaft (Vienna) had thrown on the reality of the "elementary quantum of electricity". The doubts were serious, and a detailed experimental refutation was needed to support our theoretical convictions. His later work included important discoveries in the domain of electrical discharge through gases, of the Raman effect and of ultra-sonic waves. It was right in the middle of very beautiful results on the latter phenomenon—diffraction of light by a liquid that is permeated by ultra-sonic waves and thereby turned into a diffraction grating—that his untimely death has occurred. To all this work of his a singular fact, which seldom occurs, gave a peculiarly inspiring tinge: he had begun as a pure mathematician (he had been David Hilbert's assistant during 1916–17) and ended up as an experimental physicist.

ERWIN SCHRÖDINGER.

WE regret to announce the following deaths:

Prof. C. G. Cullis, professor of mining geology in the Royal School of Mines (Imperial College of Science and Technology), on April 27.

Mr. Francis Druce, the well-known botanist, hon. treasurer of the Royal Meteorological Socity during 1913–18 and 1925–32, and of the Linnean Society during 1931–40, by enemy action.

Prof. F. Francis, emeritus professor of chemistry in the University of Bristol, on April 15.

Mr. Hans G. P. Meier, librarian of the Warburg Institute, by enemy action.

Miss J. A. Paterson, librarian of Bedford College for Women (University of London), by enemy action.

NEWS AND VIEWS

The Democracies and Honour

By means of the radio, Mr. Winston Churchill and General Smuts, who will surely go down in history as two of the leading statesmen of these days, recently gave addresses which will mark, possibly the close of a stage, possibly the opening of a new period of activity, in the progress of the War. Mr. Churchill gave a careful and moderately worded survey of the present position in the Balkans, North Africa and the Atlantic. He did not minimize the difficulties of the situation, but he made it quite clear that we could not have done otherwise than we did in answering the call of Greece; to have left Greece to her fate "would be fatal to the honour of the British Empire, without which we could neither hope nor deserve to win this hard war". It is by actions such as this, and by our bearing under the pitiless rain of blows aimed at our cities and our merchant ships as well as at our armed forces, that we have gained the admiration and support of the people of the United States, and in spite of all the arguments about American interests and safety being threatened by Nazi doctrines, "the action of the United States will be dictated not by methodical calculations of profit and loss, but by moral sentiments and that gleaming flash of resolve which lifts the hearts of men and nations, and springs from the spiritual foundations of human life itself".

By the honourable discharge of our obligations to the utmost of our available power, we have encouraged the peoples of the Balkans, and others as well, to believe in the good faith of the democracies. Whereas the Germans, Mr. Churchill said, have made "a river of blood and hate between themselves and the Greek and Yugoslav peoples", the British Empire has won admiration and sympathy. As General Smuts put it: "Great Britain has been investing in friendships, as Germany has been investing in hatreds in the process of war, and Great Britain has thus been building up the moral capital with which the real new order will be floated after the peace". Both speakers urged the need for a just appreciation of the significance of events in the Mediterranean area, but stressed that the vital theatre of war is in the West, in Britain and on the Atlantic, where the recent extension of the American neutrality patrol has given us most valuable assistance.

Aircraft Production

Speaking in the House of Lords, in reply to a request from Lord Sempill, Lord Beaverbrook recently disclosed several facts of technical interest with regard to R.A.F. equipment. One significant statement was that the Napier 'Sabre' engine has proved successful and is in production, both in Great Britain and the United States. This engine was put into production without going through the usual period of testing—a procedure contrary to all normal peace-time practice. It was designed by Major Halford, and develops a horse-power of 2,400. It is at present being fitted to the Hawker-Siddeley 'Typhoon', a new fighter capable of a speed of more than four hundred miles an hour, with a greater range than any previous single-seater type. Aircraft from the United States, including the new 'Catalina B.P.Y.' flying boat, the Curtiss 'Tomahawk', the Boeing 'Flying Fortress' and entirely Canadian built 'Hurricane' are now being received in quantities, nearly a thousand to date, and the air ferry system, by which many are delivered by air across the Atlantic, will soon be extended so that fighters as well as bombers may be sent in this way. Such journeys have been made in 7½ hours, coast to coast, compared with 20 hours, the schedule time for the American Clipper to Lisbon. The fact was disclosed that the only aircraft that has been lost during this service was unfortunately one that was carrying Sir Frederick Banting as a passenger (see p. 535 of this issue).

The development of a new high explosive bomb is proceeding successfully, and recently Squadron Leader Garner, one of the officers responsible for the technical side of this work, flew over the town of Emden with the "greatest bomb that has ever been dropped from an aeroplane", observing the effects for himself. The supply of raw materials, and equipment such as guns, navigation instruments, radio apparatus, etc., has given anxiety, but is improving. Most aircraft and aero-engine manufacturers have agreed that their demands for materials are now being satisfied, but it is admitted that a certain equipment shortage still exists. The dispersal of production centres, as an antidote to enemy bombing, is claimed to be a success. One plant, until recently on a single site, is now dispersed to forty-two centres in five different counties, and at the same time duplicate production of each item has been arranged so that the loss of any one plant cannot entirely hold up production of a unit.

Scientific Liaison with America

In a written reply to a Parliamentary question on April 29, Mr. Butler, Under-Secretary for Foreign Affairs, said: "After consultation with the appropriate authorities in the United States, His Majesty's Government have drawn up a comprehensive scheme, which has already been put into operation, for co-operation in scientific matters with the United

States of America. His Majesty's Government have selected and sent Dr. Darwin, the director of the National Physical Laboratory, as director of a Central Scientific Office, working under the direction of the British Supply Council in North America. Dr. Darwin's duty will be to collaborate with United States research bodies, to act as a channel for the exchange with the appropriate United States authorities of technical and scientific information, and generally to co-ordinate scientific and technical inquiries to and from the United States authorities, except in those matters which are already dealt with through the Service attachés. In addition, Dr. Conant, the president of Harvard University, recently visited England as President Roosevelt's representative in order to establish a corresponding mission in this country."

Advisory Committee on Engineering in Warfare

THE Lord President of the Council, with the approval of the Prime Minister, has appointed an Engineering Advisory Committee under the chairmanship of Lord Hankey to advise the Government upon engineering questions connected with the war effort and in particular: "To consider how the resources of the engineering profession can best be utilized in connexion with the war work of Government departments, and to nominate engineers who might suitably be invited to undertake particular tasks. To suggest means of improving or supplementing the methods adopted by Government departments for utilizing engineering science for war purposes. To advise on problems referred to them in connexion with the development of new engineering devices, and to advise on methods of bringing such devices speedily into production, and on means of meeting new war requirements in the engineering field. To examine new ideas or devices in engineering likely to assist the war effort, to test their technical validity, and to bring to the notice of the Government those which appear to merit further consideration by the department concerned."

The Committee will consist of Lord Hankey, Chancellor of the Duchy of Lancaster (*chairman*); Lord Falmouth (*vice-chairman*); Sir Henry Tizard, rector of the Imperial College of Science and Technology. The rest have been selected after consultation with the presidents of the Institutions of Civil Mechanical and Electrical Engineers and are as follows: Mr. J. R. Beard, of Merz and McLellan, consulting engineers; Dr. A. P. M. Fleming, director of the Research and Education Departments, Metropolitan-Vickers Electrical Co. Ltd.; Mr. W. T. Halcrow, consulting engineer; Prof. B. W. Holman, assistant professor and University reader in mining in the Imperial College of Science and Technology, London; Dr. C. C. Paterson, director of the Research Laboratories, General Electric Co. Ltd.; Mr. H. R. Ricardo, technical director of Ricardo and Co. Ltd., consulting engineers; Dr. A. Robertson, principal of the Merchant Venturers' Technical College, Bristol.

Post-War Problems for Chemical Industries

THERE has been an increasing tendency of late for presidential addresses to deal with topics that lie outside the scope of the scientific or technical society concerned. We have had physicists dilating upon metaphysics, chemists on agriculture, biologists on politics, and nearly all on education or economics. This practice is not to be summarily condemned, because it indicates that at least some scientific men are abandoning their old attitude of 'splendid isolation' from human affairs, though at times one is reminded of Bernard Shaw's dictum that no one ever learned to do one thing by doing something else. Mr. F. Heron Rogers, in his address to the nineteenth annual meeting of the Institution of Chemical Engineers, held on April 4 in London, proved no exception to this tendency. In his view, war is inevitable, and the 'fittest' who survive in life's struggles are those who are "strong in arms and in honour".

Probably the most serious after-war problem, says Mr. Rogers, will be that of finance, conjoined with the maintenance of our industries and finding work for all. In planning post-war industries, regard must be had for safety of buildings, etc., and this will be best attained by dispersion and by troglodytic working in caves. Great Britain must be made less dependent upon other countries for its necessities, such as mineral oils, timber and food. A calcium carbide industry is essential for producing acetylene and the numerous useful substances derivable from it, while further research on coal-tar products is needed to increase the number of useful aromatic compounds, like solvents, dyes and intermediates. Basic to our industrial life is research on the problem of eliminating sulphur, phosphorus and arsenic from carbonaceous materials, the solution of which would give an enormous impetus to the iron and steel industries and ease all our metallurgical operations. Research is also needed on the utilization of waste materials, which includes problems of extraction, dehydration, disintegration, pressure-filtering, and similar engineering processes. Given a period free of unwise governmental and political interference, and freedom from subsidized competition, great strides in which chemical engineering would play its part could be made towards post-war safety and happiness.

Psychological Terms used in Head Injuries

THE Brain Injuries Committee of the Medical Research Council, in War Memorandum No. 4 (London: H.M. Stationery Office. 1*d*. net), has compiled a short glossary of psychological terms commonly used in cases of head injuries. The object of the glossary is to secure a greater measure of uniformity in the terminology used in case-notes of patients with head injuries. There is always some difficulty in defining within fixed limits psychological terms, a difficulty that is increased by the fact that many of the terms are also used in popular speech with somewhat vague reference, for example, confusion, hysteria. When a patient suffering from a psychological derangement resulting from, or coincident with, head injury is referred by a physician to a special centre, it would be advantageous if the same meaning were attached to the same words. To further this aim sixteen words in common use have been defined. It is possible that another committee might have arrived at a slightly different phraseology, but although general acceptance cannot be expected, yet here is a very useful beginning, and the glossary will probably have a gradually widening sphere of application. Some of the terms defined are: *coma*, *confusion*, *delirium*, *traumatic stupor*, *concussion*, *malingering*, *hysteria*.

An Early Marine Engineering Institution

In *Engineering* of April 4, Eng.-Captain E. C. Smith gives a short history of the almost forgotten Institution of Marine Engineers, which existed from 1876 until 1879. It came to a close ten years before the present Institute of Marine Engineers was founded, and it does not appear there was any connexion between the two. The Institution grew out of a Registry of Sea-Going Engineers, afterwards called the Associated Marine Engineers, founded in the City of London. In January 1876, the *Marine Engineering News*, the forerunner of the present *Marine Engineer*, was founded, and the editor of this and the secretary of the Institution were one and the same person, Matthew Augustus Soul, a patent agent. Another leading figure in the activities of both journal and society was Nicholas Proctor Burgh, the writer of several books on engines and steam, on the latter of which he held some unusual views. The other promoters of the Institution were consulting engineers in the City of London. The aims of the Institution were admirable. Papers were to be read, a museum and library formed, and a provident fund started; but evidently affairs did not flourish, for both Institution and *News* came to a close in 1879, leaving little trace of their doings.

Meteorology in India

No drastic changes are indicated in the Report on the Administration of the Meteorological Department of India in 1939–40 (Pp. iii + 35 + 8 plates. Delhi: Manager of Publications, 1940. 1.2 rupees; 3*s*. 9*d*.). A start has been made on the construction of new buildings at New Delhi for the Upper Air Office, which is to be transferred to that city from Agra. Thirty acres of land have been acquired for this purpose, and the buildings were begun in December 1939; they were expected to be ready for occupation towards the end of 1940. The forecasting office at New Delhi, which was closed as a measure of economy in 1932, at a time of financial stringency, was re-opened, and at about the same time a new wireless station attached to the Poona Meteorological Office began to function. These last two developments allowed the Department to complete its "regional synoptic" scheme for the broadcasting of station weather reports. The stations included in these broadcasts, and in similar broadcasts from Karachi, Calcutta and Rangoon, are shown in plate I of the report, and those included in the "Collective Synoptics" in the same plate.

In addition to carrying on the ordinary routine work, so far as war-time restrictions permitted, special investigations were made, among which was one into the seismological features of the Satpura Range earthquake of March 14, 1938. Daily measurements of ozone in the upper atmosphere were begun at the headquarters' office towards the end of 1939 with the aid of a Dobson photo-electric spectrophotometer. Assistance was given to a scientific expedition from the United States under the leadership of Dr. R. A. Millikan, of the California Institute of Technology, Pasadena, mainly by the staff of Agra Observatory. This expedition made observations of cosmic rays at Agra, Gwalior, Peshawar and Bangalore, using large balloons to which were attached recording electroscopes and ion counters fitted with *radio sondes*.

New Instruments in Physics

An interesting account of the debt of modern physics to recent instruments comes from the Bell Telephone Laboratories in New York and is given by Karl K. Darrow (*Review of Scientific Instruments*, 12, 1–10; Jan.; 53–61, Feb. 1941). The instruments are classified into three types according as they are devoted primarily to observation, to measurement or to achieving new conditions. In the first article consideration is given to those instruments in which substances can be subjected to new combinations of physical forces or in which one variable is pushed to extreme limits. Bridgman's scheme for achieving pressures of the order of 100,000 atmospheres, Beams's ultracentrifuge rotating at more than 20,000 turns per second, the piezo-electric or magnetostriction oscillator, the Dickel and Clusius use of convection and thermal diffusion to separate isotopes, the attainment of vacua of the order of 10^{-8} or 10^{-9} mm. mercury, by the aid of oil diffusion pumps and 'getters', the attainment of temperatures of only a few hundredths of a degree absolute, and of high electric voltages, and magnetic field strengths are all dealt with. The second article is devoted to instruments of observation and instruments of measurement without enforcing too sharp a distinction to the two types. Both articles are well illustrated and give an excellent idea of the present limits reached in most branches of modern physics. The developments in that protean tool, the thermionic vacuum valve, and its resulting developments in acoustics are so great that another article would have been necessary to deal with them.

The Smithsonian Institution: Annual Report.

The report of the Smithsonian Institution for the year ending June 30, 1940, includes the report of the secretary, the financial report of the executive committee of the Board of Regents, together with reports on the United States National Museum, the National Gallery of Art, the National Collection of Fine Arts, the Freer Gallery of Art, the Bureau of American Entomology, the International Exchange Service, the

National Zoological Park, the Astrophysical Observatory and the Division of Radiation and Organisms. The last-named refers to further work on the problems of photosynthesis and factors affecting plant growth both from a nutritional and radiation point of view. Many measurements have been made of the rate of carbon dioxide uptake and the intensity of fluorescence during the induction period of photosynthesis, and respiration and chlorophyll studies have been continued with a recording spectrographic carbon dioxide apparatus. A standardized technique has been worked out for the extraction of plant growth substances from the oat seedling. Publication of the final revised values of all solar constant results from all observing stations from 1923 to the present time is expected during the coming year. Archæological excavations in south-east Mexico have been continued in co-operation with the National Geographic Society. Excavations at the Lindenmeier site in northern Colorado have afforded much additional evidence of the presence of Folsom man.

Publications handled by the International Exchange Service, which serves as the official agency in the United States for exchange with foreign countries of documents and scientific publications, considerably decreased during the year, as the exchange of publications was suspended between the United States and all European countries except Great Britain, Finland and the Soviet Republic. A list of foreign depositories of Government documents is included in the report. The work of the Astrophysical Observatory concerning the radiation of the sun has been continued, and Dr. C. G. Abbot has endeavoured to evaluate the separate influences produced on weather by long-range solar periodicities, and changes in phase of the weather responses have been found to be due to seasonal influences.

Recent Earthquakes recorded at Kew

During the week April 13–20, six large earthquakes were recorded at Kew Observatory. Three were on April 15, and there was one each on April 18, 19 and 20. The first on April 15 was very distant and the second was the important earthquake with epicentre near Colima (Mexico) (Nature, April 26, p. 507). This began recording with *iP* compressional on all three components at 19h. 22m. 19s. G.M.T. on April 15, and there followed a full suite of pulses, including *iS* on all three components at 19h. 32m. 39s. G.M.T., eL_Q on N and E at 19h. 46m. G.M.T., and eL_R on the vertical and E components at 19h. 50m. G.M.T. The earthquake finished recording at midnight on April 15, but what was probably the *iP* wave of an aftershock recorded on the vertical component seismograph at 19h. 58m. 25s. G.M.T. on April 15, superposed on the first. The maximum of the chief earthquake attained a ground amplitude of 880 μ at Kew. The shock on April 18 only gave rise to small amplitudes. The one on April 19 recorded *iP* dilatational on the Z component at 8h. 4m. 23s. G.M.T. and probably had its epicentre 7,220 km. away. The earthquake on April 20 attained an amplitude of 69 μ at Kew and was the second largest in the week. It began recording at 17h. 47m. 17s. G.M.T. with *iP* on the Z component probably from an epicentral distance of 5,440 km., and finished recording at 18h. 40m.

Earthquakes recorded in Switzerland

The Swiss Earthquake Bulletins from Zurich for November and December 1940 have just been received. Eight large earthquakes were recorded in November, and 10 in December. The earthquake of November 7, 1940, was recorded at all four observatories of Zurich, Chur, Basel and Neuchâtel and was felt with intensity IV at Gemeinde Muotatal, and at Schwyz with intensity III–IV. The earthquake of November 10 may have had its epicentre near Bucharest, and several aftershocks were also recorded. The shock of November 19 may have been near the Pacific Coast of northern Japan. On December 12 an earthquake, recorded at Chur, Zurich and Basel was felt with intensity IV in the region of the Mürtschenstock, Kt. Glarus, whilst the shock well recorded on December 22 at all four observatories, and in particular at Neuchâtel at 19h. 12m. 36·9s. G.M.T., probably had its epicentre in Central America.

Announcements

The title of reader in histology in the University of London has been conferred on Mr. Keith C. Richardson in respect of the post held by him at University College.

The Institute of Wireless Technology and the British Institution of Radio Engineers have fused, and in future the combined body will be known as "The British Institution of Radio Engineers Incorporated with the Institute of Wireless Technology". The president is Mr. S. A. Hurren, and Mr. G. D. Clifford has been appointed general secretary. The first annual general meeting of the combined body will be held in June, when the election of a council for 1941–42 will take place. All communications should be addressed to the Institution at Duke Street House, Duke Street, London, W.1.

A recent issue of the *Evening Standard* (London) quotes a British United Press message stating that traces of "a hitherto unknown prehistoric civilization have been found at Ipiutak on Point Hope, Alaska". It was already known that a very early and well-developed culture existed in Alaska, and the above message suggests new finds, confirmation of which will be awaited with interest.

There seems to be some misunderstanding concerning the leading article entitled "Relationship of Pure and Applied Biology" which was published in Nature of April 12, p. 427. As a leading article, the views expressed are, of course, those of the editors of Nature (formulated after considerable inquiry), and not those of a single individual. Neither is the article a summary of the discussion (to which reference is made) at a joint meeting of the Association of Applied Biologists and the Society for Experimental Biology. Summaries of discussions are published as such, and not as leading articles.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

A Possible New Approach to the Study of the Hydrogen Bond in Protein Structure

IN a recent review[1] Astbury has pointed out that the role of the hydrogen bond in protein structure, usually ascribed primarily to the keto-imino group, is largely unknown. Determination of the structure of such polar groups in the aqueous medium necessary for the normal functioning of the protein molecule is not easily achieved by means of the usual X-ray and infra-red methods. The monolayer technique has, however, proved of value in certain cases[2], and recent measurements upon simple compounds containing the –CO.NH– link indicate that cross hydrogen bonding between such groups does occur in water provided that the molecular spacing is suitable.

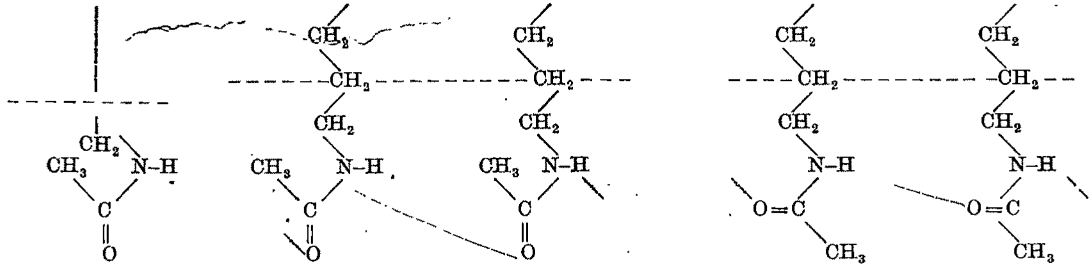
Condensed monolayers of acetamides and ureas were shown by Adam[3] to exist in two forms with a definite transition temperature, the latter being unusual in giving solid films even at an area of 26 A.^{2}. (Solid monolayers are usually only obtained with close-packed, vertical chains at 20–21 A.^{2}.) These and other facts are readily explicable by assuming cross hydrogen bonding between the molecules in the monolayer. A comparison between substituted amides and the corresponding esters which cannot form cross hydrogen bonds, for example, octadecyl acetamide and acetate, methyl stearamide and stearate, shows that the former tend to give very stable solid, and the latter much less stable fluid, films. The half-expansion temperatures ($T_1/_2$) given by Adam[4] are also much higher for the compounds for which cross hydrogen bonding in the monolayer is now postulated (amides, ureas, aldoximes and acids), and the tendency towards solidification is also very apparent (see accompanying table).

Calculation of the hydrogen bond distances in the various cases gives results in quite good agreement with known values; for example, acetamides 2·8 A. at 21 A.^{2}, ureas 3·2 A. at 26 A.^{2}, acids 2·8 A. at 24 A.^{2}.

The above principles are shown up most clearly by the acetamides which have now been studied in detail by both force-area and surface potential methods. The figure below shows the head-group configuration deduced for the expanded state and for the high- and low-temperature condensed forms.

Chain-length $C_{16}H_{33}$ in all cases.

Head-group ..	$-O.CO.CH_3$	$-COCH_3$	$-COOCH_3$	$-COOH$	$-CHNOH$	$-CONH_2$	-NHCON H
$T_1/_2$	20°	33°	34°	37·5°	42°	44°	48°
Nature of condensed film	Liq.	Liq.	Liq.	'Plastic solid'	Not known	Solid	Solid



EXPANDED FORM
$A > 47$ A.^{2}
$\mu = 302$ milli-Debyes
No cross hydrogen bonding.
Liquid film.

HIGH *T*. COND. FORM
A c. 24 A.^{2} (tilted chains)
μ c. 350 *m–D*.
Weak hydrogen bonding (bond distance *c*. 4 A.).
Liquid film.

LOW *T*. COND. FORM
$A = 21$ A.^{2} (vertical chains).
μ c. 390 *m–D*.
Strong hydrogen bonding (bond distance *c*. 2·8 A.).
Rigid solid film.

(Water surface undefined but parallel to the horizontal dotted line.)

In the acetates configurations almost identical with the first two are known[5], but there is nothing at all analogous to the third, where stabilization is obtained by cross hydrogen bonding. In addition to the hydrogen bond distances it is also possible to calculate, approximately, the free energy difference between the –CO.NH– group when forming hydrogen bonds with water (as in the expanded films), and when cross-linked (as in the low-temperature condensed form). The latter is found to be the more stable by about 800 cal./gm. mol.

The stabilizing action of the cross hydrogen bonds can be decreased, leading to liquefaction, by strongly acid substrates (for example, $5N.H_2SO_4$), as well as by increase of temperature. The effect of other reagents, such as urea, is being examined.

Similar considerations can be advanced to interpret the monolayer behaviour of the ureas, other amides, aldoximes, unsubstituted and α-amino acids, as well as mixed films, and will be given with further details in a forthcoming publication.

Organic Bond Strengths and the Heat of Vaporization of Carbon

KINETIC studies on several independent chemical reactions have led to a value of about 104 kcal. for the heat X of removal of the first hydrogen from methane. Thus Trenner, Morikawa and H. S. Taylor[1] obtained 108 ± 5 kcal. from the reaction of deuterium atoms with methane, Patat[2] a value of about 103 kcal. from the *ortho-para* hydrogen conversion by methyl radicals, and Rice and Dooley[3] a value 100 ± 6 kcal. from the thermal decomposition of methane at high temperatures. Butler and Polanyi[4] have measured the velocity of the homogeneous thermal decomposition of alkyl iodides at low pressures, and their results, together with some thermo-chemical data, lead to the value $X = 103{\cdot}6$[5].

From this value and the known heats of reaction, $2CH_4 \rightarrow C_2H_6 + H_2$ and $H_2 \rightarrow 2H$, the C–C bond strength in ethane is 88·2[5]. (Rice and Johnstone[6] from the concentration, at various temperatures, of free radicals in ethane obtained a value of about 80 kcal.)

In his recent book "The Nature of the Chemical Bond"[7] Pauling has recommended an average bond strength for C–C of 58·6 kcal. It is the object of this letter to point out this serious discrepancy and to suggest an explanation; the variations in bond energies established by Rossini[8] are too small to account for it. Since Pauling's C–H bond strength (87·3) "is the value given by methane", that is, the average of the heats of the four successive hydrogenations of a carbon atom, a possible explanation is that the *first* C–H bond broken in methane is considerably stronger than the others. This would lead to too low a value for the C–C in ethane. Taking this first bond strength as 104 and assuming Pauling's average value, the average of the other three C–H bonds would be only 82 kcal. Two arguments oppose this interpretation: (1) Voge[9] has calculated the energies of these successive reactions approximately by quantum mechanics and obtained no such large differences. (2) The heat of successive substitution of the hydrogens in methane by a halogen varies but little along the series given by each halogen. Thus from the data for the heats of formation of the appropriate compounds given by Bichowsky and Rossini[10], these substitution heats are (for the processes $CH_4 + \text{Hal.} \rightarrow CH_3\text{Hal.} + H$, $CH_3\text{Hal.} + \text{Hal.} \rightarrow CH_2\text{Hal.}_2 + H$, . . . etc.): for substitution by Cl, − 21·1, − 21·4, − 21·1, − 20·7, by Br, − 35·0, − 32·5, − 32·0, − 31·0, by I, − 49·0, − 46·8, − 45·3 (fourth step unknown). It is difficult to see how such constancy for all three halogens is compatible with a large variation in the C–H bond strengths.

If, therefore, this hypothesis is excluded, Pauling's table of carbon bond strengths must embody some systematic error. The obvious possibility is uncertainty in the heat of formation V of carbon, as monatomic vapour, from carbon in the standard state (graphite or diamond). Two methods exist for the determination of V: (*a*) the spectroscopically observed dissociation energy of carbon monoxide can be related to it by known combustion heats; (*b*) by observation of the vapour pressure of graphite. Goldfinger and Jeunehomme[11] have considered that method (*a*) leaves three values possible: − 168·8, − 123·6, and − 107 kcal. They calculated the vapour pressures corresponding to each and compared these calculations with experiment. Their results show that the lowest value is very improbable, but, although the most modern and accurate determinations agree best with the highest of these three values, they adopt $V = -123{\cdot}6$, the value recommended from considerations of spectra by Herzberg[12]. As Herzberg pointed out, the vibrational levels are insufficiently known for a Birge-Sponer extrapolation, so that the evidence for V depends on the interpretation of certain predissociation limits and the assumption that these are not 'accidental'; moreover, Schmid and Gerö[13] have considered these data as supporting a value of V of only 73 kcal., which is on chemical grounds very unlikely. The spectroscopic results are not, therefore, unequivocal, while the high value 168·8 is supported by some calculations (of which the details were not given) by Penney[14], who obtained $V = 170$, "a value unlikely to be in error by more than 10%".

Now it can be shown that in these average bond strength systems, if V is too low by x, the C–H value will be too low by $\frac{1}{4}x$, the C–C by $\frac{1}{2}x$, and the C=C by x. If we take the high value 168·8 for V, Pauling's C–H of 87·3 becomes 98·6, his C–C of 58·6 becomes 81·2, and his C=C of 100 becomes 145. A similar correction to the 'average' bond strengths of Sidgwick[15], who took $V = 150$, gives for the aliphatic series C–H 98·4, C–C 81·1, C=C 143. These corrected values agree, to within the uncertainty inherent in 'average' bond strengths, with those derived from consideration of the decomposition kinetics of alkyl iodides[4,5].

The single assumption, therefore, that the heat of vaporization of graphite to monatomic carbon vapour is 168·8 or thereabouts is sufficient to reconcile the serious discrepancies between 'kinetic' and 'thermochemical' values for carbon bond strengths. In view of this fact, it would be of interest if further spectroscopic research could give a definitive answer to this question of the heat of dissociation of carbon monoxide.

Use of Silver Nitrate for the Histochemical Demonstration of Ascorbic Acid

SILVER nitrate in acid solution has been widely used for the study of the distribution of ascorbic acid in tissues and cells[1]. A survey has recently been made, using this method, of its occurrence in chick-embryos[2]. During this study a previously unreported phenomenon was observed in newly calcified bone: this was a heavy dark deposit which filled many of the newly formed trabeculæ of cartilage and membrane bone. The histological picture was similar to that produced in developing bones by the use of von Kossa's silver nitrate technique for the demonstration of calcium. A related phenomenon has been observed in the long bones of adult rats, which become bright yellow on treatment with acid silver nitrate. In specimens from both these types of bone prepared for histological examination there are seen dark deposits in many of the trabeculæ, quite different in character from the small black granules seen in other tissues treated by this method.

In view of the possibility that the atypical deposits seen might have been produced by the precipitation of a silver salt, followed by photo-decomposition of the salt during the preparation of sections, the following experiment was made. The femurs and frontal bones from twelve chick embryos of various ages were used. One frontal bone and one femur from each embryo was treated in the normal fashion and one frontal bone and one femur was placed in 5 per cent ammonia for 10–15 minutes after fixation in acid silver nitrate and washing in water. Fixation, washing and treatment with ammonia were carried out in brown bottles in each instance. In all instances in which acid silver nitrate produced discoloration of the bone, subsequent treatment with ammonia restored the normal appearance, and atypical deposits were absent in histological preparations. Similar results were obtained with rat bone. Treatment of rat adrenals with ammonia after fixation in acid silver nitrate had no effect on the histological picture.

These results indicate that in some tissues the histological picture produced by the reduction of silver nitrate in acid solution by ascorbic acid may be complicated by a process which is probably due to the precipitation of silver salts followed by photo-decomposition; this complication can be obviated by treatment of the specimen with 5 per cent ammonia. It is suggested that this treatment with ammonia after fixation in acid silver nitrate constitutes an improvement in the technique for the histochemical demonstration of ascorbic acid, in that it increases its specificity.

Dependence of the Direction of Rectification in Copper Pyrites on Voltage, Temperature and Time of Measurement

The reversal of rectification by heat in molybdenite[1] led to the study of the rectifying properties of copper – copper pyrites contacts. In most cases, it has been found that below 1 steady volt the normal direction of easy flow is from the metal, but it reversed between 20° and 200° C. For voltages of the order of several volts, the conductive direction is from the crystal, but it reversed between 20° and – 78° C. The relation between the transition voltage and the transition temperature indicates that above a critical temperature of about 500° K., or above a critical P.D. in the neighbourhood of 20 volts extrapolated at the absolute zero, the direction of rectification is always the same. A similar phenomenon occurs in thermocouples when the cold junction is above the neutral point, or when the temperature difference between the two junctions exceeds twice the neutral temperature.

On changing from D.C. to A.C., it is occasionally observed that the direction of the rectified current is opposite to the direction of the larger current. This is explained by a time lag in the current, arising from the contribution of some integrative action related to the direction of the applied voltage.

Sense of Hearing in Fishes

In his review of our knowledge of the sense of hearing in fishes, von Frisch[1] only quotes one observation in the field, and in his summary says, "spontaneous reactions to musical tones are not to be expected, since the sound signals used by us have no biological significance for fishes. Reliable reactions can therefore only be obtained by conditioning to tones."

It may therefore be of interest to put on record an observation that I made some years ago in British Guiana on the response of fishes to sound under natural conditions. I was at the time visiting at frequent intervals Plantation Ogle, a sugar estate in the low-lying coastal area south-east of Georgetown. The estates are drained by a number of shallow canals along which the sugar-cane is towed in barges to the factories, and there are many low humpbacked bridges over these canals.

I find in my note-book the following, dated September 16, 1916. "In crossing a bridge over one of the trenches I noticed that numerous small fish were surface feeding in small groups in the water, but at an accidental noise they all dived deep. I tried waving my arms suddenly without noise but this had no effect. Clapping my hands or ringing my bicycle bell, on the other hand, caused them to dive so suddenly that the whole surface of the water was disturbed." I repeated the observations on several days and distinctly remember one experiment in which I laid my cycle on the ground and crouched low so that I could only just see the surface of the water. When I rang the bicycle bell, the only movement being that of my thumb which was in any event quite out of sight of the fishes, the response was immediate and striking.

There is no doubt in my mind that these fishes heard and reacted to a sound which, according to von Frisch, should have "no biological significance" to them; but what natural warning sound, if any, it simulated I am unable to suggest.

Perhaps some resident of British Guiana could repeat my experiment and get some of the fish identified.

I may add that I have recently tried the effect of a bicycle bell on goldfish in a pond here at Rothamsted but cannot see that the fish respond in any way.

The Cleavage in Biology

THE leading article on the "Relationship of Pure and Applied Biology" (NATURE, 147, 427; 1941) paints a lamentable picture of the separation of pure and applied biology, lamentable because, as it claims, each is needed to fertilize the other. The article explains how in the universities research has become an end in itself and purity its ideal. It implies also that in research stations utility often provides an opposite and exclusive ideal. Each of the two ideals justifies its own kind of enthusiasm for research and persuades us of the reality of the opposition between them. Nothing but good can come of showing that the opposition is unnecessary; that snobbery and counter-snobbery are equally artificial, and that pure research can develop as it should develop only if it is continually harassed by the demands of necessity. It is the absence of necessity or apparent use that in past times has often led science, or some parts of it, into backwaters where the inevitable weeds of scholasticism have clogged its stagnant channels.

All this is clear enough; but it is not the root of the matter. There is, as the article says, underlying the cleavage of ideals a cleavage of organization and material resources. With a few important exceptions there is a division in biological research between those who have to teach in the universities and are free to follow pure research in their spare time, and those again who work in research institutes of medicine or agriculture and who to a greater or less extent are expected to achieve practical results. Each party develops its own comfortable philosophy, comfortable at least in a stable environment. *Il n'est point de sot métier.*

The separation of teaching from applied research does harm to the research. New recruits to research from the universities have to unlearn a great deal of what they have learnt and, having in this way lost their simple faith, stand a poor chance of being allowed to teach again. But consider the harm it does to the teaching. A professor of botany told me recently that it was no use trying to develop the teaching of botany into something more useful since botany was only taught to people who would teach botany to people—and so on for ever. This is the principle of the 'fundamental training' seen from the other side of the hedge. Is it any wonder that the standard university text-books scarcely mention any of the uses that can be made of a knowledge of plants and animals? And that they confine their statements about genetics and cytology, for example, to a reiteration of formulæ which have obviously meant as little to the men who write them as they will to the men who read them?

Surely then the remedy is not, as the article proposes, an interchange of personnel between institutions which continue to pursue divergent paths of pure and applied research. Such a policy would touch only the surface. No, the union of interests must be complete. The divergence must be suppressed; and it must be suppressed by the fusion of pure and applied research, by the fusion of both with teaching.

A radical reconstruction is therefore needed in the relations of teaching and research, of universities and stations. Let no one object that fearful obstacles lie in the way. Of course they do. Thirty years will be needed to accomplish the change. But accomplished it will be.

Once an organic union of the two parties is established the rest will follow. Syllabuses will be revised, the necessary 'fundamental training' will become much more fundamental and much more of a training. The sterile separation of botany and zoology will become a fruitful union. The combination of small departments will bring them to a size suitable to the work in hand. The importance of chemistry and statistics and even downright craftsmanship will be admitted and exploited; and, by accident or design, the impossible hope of NATURE will have been realized—a training in biology will have become an education in itself.

C. D. DARLINGTON.

John Innes Horticultural Institution,
Merton Park,
London, S.W.19.
April 18.

As Dr. Darlington points out, the divergence between pure and applied biology must be suppressed "by the fusion of pure and applied research, by the fusion of both with teaching". Thirty years, indeed, will be needed for this, if not much longer. To effect this remedy immediately is, of course, impossible; then surely the suggested interchange of personnel should be the immediate aim with complete fusion as the ultimate aim.—Editors of "NATURE".

"The Man of Science as Aristocrat"

IT is indeed a privilege that in NATURE we can enjoy an article by Mr. H. G. Wells. I, like him, would like to preface the remarks I have to make upon his contribution by paying my modest tribute to NATURE. I know nothing more wholesome than a perusal of the "Letters", at least 50 per cent of which must be pure gibberish to most people, but absorbing to the few interested in their particular subject raised. Humility of mind over such abysmal ignorance of so many subjects is a fine correction in these days of the 'cock-sure'.

H. G. Wells obviously comes under the head of a man of 'general intelligence'. I make no such claim. I get included by virtue of "a broad curiosity outside the ranks of the specialist worker".

In a debate on Mr. Wells's recent lectures in the United States and why he was allowed to go and air such curious views Mr. Peake, speaking for the Government, put up an admirable defence of his conduct on the ground that we all knew Mr. Wells and that we must look upon him as one of our "invisible exports". I have never quite decided whether Mr. Peake meant very subtly that we can all see through Mr. Wells or not, for although he derides the patent laws and condemns them—"we must all work for the common good"—, I see no urgent advocacy of the abolition of copyright. The miserable capitalist world that recognized Mr. Wells's genius has by its machinery not only kept him from starvation and being 'bumped off', but also made him incidentally one of the most privileged of the privileged classes.

Success in literature has been his, with its reward. If he had levied toll on the world for his invention of the cinematograph, would the "arrogance and detestableness of his nature" have been brought out? Certainly not. It was not brought out by his success in literature for the reason it was not there. A more lovable, maddening man I have never met.

Mr. Wells makes a plea for the man of science to look upon himself as an aristocrat. This, indeed, must make Robespierre turn in his grave, and surely in some States must put some of our friends in danger. To jump from the proletariat, ignoring the *bourgeoisie*, to be an aristocrat, would certainly endanger, I should imagine, Prof. Kapitza's life. Dangerous advice from a socialist; but we get his meaning. I do not think his tongue was in his cheek when he wrote that, but, when Mr. Wells writes, the position of his tongue is important, which goes to show the superiority of the spoken over the written word.

My point is, why should the man of science look upon himself as an aristocrat? Granted, he may be doing work which will be of use to the world and not to himself; a soldier also does that. A man of science works at the subject he adorns because that is his bent in life and where he can best satisfy himself. It does not follow—brutal as it sounds, it must be made clear—that because a man of science is brilliant in his sphere he can take on any job and shine at it. A man can be a brilliant man of science but unable to make his way in life in any other direction. Even Sir Isaac Newton never shone as a member of Parliament. A well-known fellow of the Royal Society complained to me the other day that working as he did in a particular Ministry he was valued for pay on the basis of a major, and I am brutal enough to think that that is about right, once a specialist gets out of his groove.

I agree that the man of science and the specialist working in his groove have produced in our time the motor-car, the aeroplane and the radio, which by the 'wisdom' of man have been turned into the Panzer Division, the night bomber and lying propaganda. All this is indeed desperate, but it does show that technical minds outstrip political wisdom and that it is easier to discover X-rays than to placate Europe.

The sort of article Mr. Wells has given us tends to get all values wrong. Technical research may benefit the world or not, that depends on how it is ultimately used; but for the advancement of the general happiness of mankind concentration by the brains of the country is required on government and planning. That is the most difficult and important of all science. I suppose Mr. Wells would class it as politics and fire squibs at it; but because it is neglected and despised, because there are no chairs and no places for its students in the Royal Society, the most difficult of all subjects is being neglected as science.

Let us get our values right. The man who by his political efforts can get adequate milk to children deserves more of his fellow men than the inventor of the quantum theory; but in the narrow world of science, who gets the most attention and encouragement?

Aristocracy means government by the best. If the man of science means to come out of his shell and help us in the problems and perplexities of life, good luck to him. What we can do without, however, is the specialist, usually with the pen, divorced from all the responsibilities of public life but laying down high priestly criticisms of all and sundry, as if knowledge, foresight and wisdom lay with him alone.

J. T. C. MOORE-BRABAZON.

Ministry of Transport.
April 25.

ACCORDING to Mr. H. G. Wells, it would appear that inventors and research workers must be stoically and aristocratically resigned to even worse conditions under democracy than they have hitherto endured under pluto-aristocracy.

But, surely, if democracy abolishes the rich patron, it must be prepared to wear his mantle and do his job.

The precedent is already to hand, for example, in the Civil List, from which State payments—pensions or gratuities—are already made to deserving individuals. It would, of course, be necessary to organize an extensive machinery for administering State patronage—as of right—to all deserving cases; but the advantage to the cause of national progress might be very great. Inventors, research workers, artists and the like would at last be protected from the "Smart Alecs"—they would be rewarded by the State in proportion to the benefits they had rendered to the community.

As to the scale of payments—a progressive manufacturing firm may spend from 1 per cent up to 2 or 3 per cent of its annual turnover on research and development; a wise and progressive democracy might well do the same, and spend as much on research and development as we have hitherto done on national defence.

The same organization might, with great advantage, have the duty of recommending the bestowal of national honours for public services rendered.

'Pancake' Ice in the Pennines

ON February 2 during a severe frost a visit was made to High Force in Upper Teesdale. The Force was a spectacular and beautiful sight, with a considerable cascade of water descending between great curtains of ice, and heavy icicles draping all the surrounding cliffs formed by the Whin Sill. But it was the pool below the fall itself that invited special attention and comment. Here on the agitated surface were floating rounded pieces of ice, formed apparently at the height of the frost on the pool-surface, which later became disintegrated. Some fragments, however, may have been derived from the surrounding walls, or have descended by the cascade from the upper reaches of the river. Mr. Bentley Beetham, of Barnard Castle, who accompanied me and who has before seen the Force under frozen conditions, favours the first-mentioned alternative for the origin of the ice-glaçons.

It was noticed, moreover—and this is the main point of interest—that the glaçons were not merely rounded, presumably by attrition in the agitated water, but also had their borders sharply raised in the manner of 'pancake' ice of the polar seas. The 'pancakes' were up to about one foot in diameter, and would seem to have been formed under such conditions of temperature and movement—in order to provide the correct plasticity and shape respectively—as are to be found in the well-known examples in the arctic and antarctic seas. The latter have been strikingly illustrated in Wright and Priestley's "Glaciology" of the Scott Antarctic Expedition, 1909.

It is not known that pancake ice has been described from other than polar regions.

TOWARDS A NEW GEOGRAPHY

By WILLIAM A. GAULD,
MONMOUTHSHIRE TRAINING COLLEGE, CAERLEON

WHATEVER shapely forms the new world of reconstruction will take no one is certain as yet. It will be well if we stand firm in the belief that what we must start from is not some blue print or paper scheme, but from where we are now. The way the nation thinks must be determined, to a large degree, by the way it is taught. An overhaul of our educational system, an examination of the validity of the principles and facts inculcated into the minds of young people, might be a valuable contribution by educationists to the new order democracy hopes to build.

It is with this idea in mind that this article takes up the question of geography as a subject learned and taught. Greek interest in the *oikumene* started off a long lineage of environmental study from Strabo to Bodin, Buckle, Ritter, Herbertson, Geddes and many others. The duality of the environmental concept-man and Nature has been constantly attracting philosophy and science. We are now some distance from Montesquieu, who explained the virtues of the English constitution by the vices of its climate; but determinism will out, and mole hills of causality become mountains of effect. Convention ties the geographers to the bed rock of physical elements, and their human geography is still too much a product of the soil.

In a chapter on the geographical factor in his "National Character", Prof. Ernest Barker, quoting in some degree from the work of Edouard Meyer, has shown some of the fallacies of determinism. It is man, he says, who arouses the dormant energy of natural resources and makes them geographical elements. Coal and iron had been in our soil for millennia before man used them and made them factors in our economic situation. Again, the sea was at our gate for countless ages before we became a maritime nation. Prof. Toynbee in his recent work gives full play to environmental forces in tracing the history of civilizations, and he finds psychological factors as potent as physical, and spiritual vitality as determinant as climate and soil. Febvre again goes so far as to say that it is human activity, not soil and situation, which governs the game. There is no 'law of islands' imposed on human society, only variety and difference. Michelet could say of Flanders, "it has been created so to speak in defiance of Nature. It is a product of human labour". All of which seems to imply that man is a geographical agent, and that if history, as Prof. Rait says, is largely what geography makes it, geography is no less the product of history. The environment of to-day is the sum of all our yesterdays.

It is true that our geographers of to-day allow more room to human initiative and will than of old, but they have a speciality to conserve, and they make strange claims for it. Now it is merely 'a point of view', now 'a synthesis'. As a way of looking at world phenomena the geographical aspect is possibly a necessity in particular cases, but that scarcely makes it a subject. The claim to be a synthetic study results from the method. If you collate data from all and sundry sources you must synthesize or suffer mental indigestion. The trouble is that in fact the geographer has to select what is digestible, but a partial synthesis is not scientific. This may be illustrated by reference to that excellent little classic on "Modern Geography" by the late Dr. Marion Newbigin. It presents a sequence of the varied content of conventional geography. There are the physical aspects of natural landscape, the biogeography of plant and animal life, and the relations of these with human society and its activities. It presents a rational picture of man and Nature; but what concerns us now is that the relationships which in the synthetic view should be cardinal, are but fractional. The elements exist in themselves, and they get on very well without being related. Synthesis in fact is a deliberate and consciously applied process, not one which operates in virtue of the coincidence of distributions.

Again, we may say that the physical map is the foundation of regional analysis, that certain results follow from given terrestrial forms; but there is nothing inevitable in any particular set of circumstances, and differences in effect may be more striking and significant than identities. The result of generalizing as to relations from specific examples is analogous to seeing the wood without perceiving the trees. Climate and vegetation regions there may be; but the real interest and importance often lies in the differences in superficially identical distributions. Grasslands may look all alike on the vegetation map, but they are not so in reality. The transformation of the Argentine pampas by artificially sown grasses is not represented on most maps in current usage.

Geographers seem to spend an inordinate amount of time in the classification of phenomena, and the atomization of regions in particular seems to have reached to ridiculous lengths. The 'natural region', once so fundamental as the epitome of physical and human interactions, has become a wanton unloved by the many, though most are loath to abandon it. It would have been better perhaps to leave it in its original literal sense as a Nature-made region as distinct from the cultural region which bears the impress of human activity. At any rate, hunting down regions as an end in itself has gone far enough. At best they are just frameworks, and what really matters is what is built into them.

A word may be said here about what might be termed 'map idolatry'. The map has been the sheet anchor of the geographer. There is a curious belief that it is a basic element, and that everything begins and ends in a map. Now maps are often as beautiful as they are useful, but even the best of them is merely a symbolic representation of selected facts. They are built up of layered distributions which are necessarily incomplete. A map leaves out much more than it can ever contain, and a great deal has to be read into it before it can mean very much. In short it is an auxiliary, not a fundamental element. It is a mistake to suppose we can base a serious study on empirical documents. A map is to the geographer what the time-chart is to the historian, merely a convenient method of setting out a proportion of the facts, not an original source material, for it is already a synthesis.

If the geographer still clings to deterministic frameworks, it may be claimed that he has escaped from causality. It is true that a rather vague 'possibilism' of Gallic origin has been substituted—influences replace conditions. So far the change in emphasis has not produced any great revolution, and text-books and the man-in-the-street still argue causally on environment. Yet the dominance of man as a geographical agent is obvious. His intelligence, if not always his wisdom, is at work, and he has altered the face of Nature so much that a cultural has replaced the Nature-given pattern. Examples are abundant. Railway and road construction, airways and shipping lanes, irrigation, the transplanting of crops and resources, plant genetics, and so forth. The rape of the earth may be only one side of the story ; but at least it is evidence of human energy and activity.

What emerges is that the whole traditional approach to geographical questions needs revision, in that conventional geography still assumes man as an effect and not as a cause. Since palæolithic times man has never left the terrestrial scene, and both Nature and man are dynamic forces, and in a general sense man has been historically the dominant partner.

Any human group and any area may be said to be affected by two elements. One is made up of the internal and local influences operating by direct contact, and the other comprises all those external agencies which may be local or world wide, and which may or may not be more potent than those native to a given group or area. In contemporary society the 'home geography' is more and more a reflection of wider impacts which are breaking down isolation and modifying local characteristics. This species of universal leavening is, of course, a slow process, no doubt desirably so, and the universal pattern is much less well defined than local regional features at the moment. Yet this, too, carries with it the implication that human forces and actions have wrought and are still working transformations which demand a new approach to geographic studies. If, as has been implied, man throughout history has modified the natural landscape and given it ever-changing influences, it follows that the geography of the past, apart from physical changes, must be largely the record of his activities. Here is the true historical-geography, and most of that has yet to be written. This evolutionary aspect of environment, changing in substance and in incidence, is a matter of history, a 'natural history', with its central theme the place of man, creative man, in the development of the natural world.

"Geography is about maps, history is about chaps", so the schoolboy is reported. Discussions about the relations of history and geography, the meaning of historical-geography, and so on, have been held frequently, but as yet the bridge between the two subjects is still to seek. The study of a border-line marginal area necessarily makes difficult the fixing of limits. Framed as is our academic practice within a group of 'subjects', there seems no place for the historian-geographer or the geographical-historian. He should be obviously a free agent, free to draw on historical and geographical matter with whatever emphasis truth seems to require. He should not have to argue the historical factor in geography or the geographical factor in history according as to whether he is in the historical or the geographical camp. In practice he has to live and must perforce line up with one or other of the recognized 'subjects'. The divorce of man and the *oikumene* as subjects of study has resulted in the cleavage we now see. The pre-historians and the archæologists at the moment seem to be most successful in the handling of the dual theme. Too much of what passes as historical-geography suffers by the separation of bones and flesh. The historian is too often content with an introductory chapter and ignores the fact that his 'stage' is there all the time, and the scenes change, while the geographer it might be said is too interested in the decking and stage 'props' to notice much difference in the actors. There is an aridity which results from the isolation of physical and material factors as subjects of study apart from their human setting. It is man who gives them the stature that they have.

The major function of geographical study is to delineate the features of the contemporary world, and while the present has its roots in a past, and is not intelligible without some reference to that past, there is a justifying substance in contemporaneity. Things happen somewhere now as well as then. When the servant girl in Mr. Coward's play asks "Where is Africa ?" her query expresses very well our general attitude to strange places. For most people acquaintance with the world about us is embodied in a cartographical outline dimly recollected from schooldays, with some detail here and there perchance remembered, but no catholic knowledge of the living societies, modes of activity and organization which function inside the framework. Geography in general education covers that area of knowledge which is concerned with international questions, political and economic features, trade and communications, and the exploitation of resources. An understanding of the nature of an integrated world order, a society of elements separate and self-contained but forced into contacts and relationships —this seems an obvious need. The older latitudinarian treatment of political and economic geography might well be revived to offset our current practice of putting everything into the regional pot. Here again the difficulty is in determining what is specifically geographical and what is not, and the question arises also as to the desirability of separating out an aspect which may only have significance in its relation to more directive and active forces. What is wanted both in the regional analysis and in the broader studies on a world basis is, so to speak, less anatomy and more physiology, less of structures and more of functions. The world is a going concern and its mechanism is in motion, while we tend to regard it as if it were at rest.

'Human geography' was a term introduced to describe all the geographical elements which were not Nature-given. It admitted man as a factor in the equation, rather grudgingly perhaps. It is a long jump from this to the latest school of geographical philosophy, that of geopolitics. Swedish in origin, this geopolitical school has found its home in Nazi Germany. It thinks of blood and soil as destiny, and its main tenet is that State, race, and land must be regarded as an organic whole, as a metaphysical entity in which the citizens exist only in and for it, while at the same time it is more than the sum of the nationals who compose it. This spurious pseudo-science is in the Ratzel tradition, and we are right back at determinism again. It is the concept of *Lebensraum* which justifies the essential geographical basis of this ideology, for terrestrial expansion of living space is a concomitant of it. The best that can be said of this warped and distorted philosophy is that man is given a more potent if not a higher place than in some other terrestrial philosophies.

The recent revival of mechanical conceptions of society are perhaps a reflexion of the instability and lack of conscious political purpose of a world society in which economic factors and modes of physical contact are establishing a new segregation of population, and in which time-distance has so largely replaced linear distance.

If there is any validity in these reflections on the present condition of geographical study, it becomes evident that some changes in principles and methods are called for. The restoration of man and his mind to their proper sphere as purposive and active elements rather than passive agents, is beginning to appear in some kindred sciences such as physics and biology. Dr. Isaiah Bowman has written of the "timeless creative experiments" which man is participating in, and geography as one of many forces which are involved in it. Man appears in the world but is not altogether of it. As a tool-using animal he gave expression to powers and forces not hitherto known to Nature, and if he remains still part of Nature he carries some evidences of spiritual resources which Nature may utilize, but she cannot endow him with them. Let the argument start from the spiritual ancestry of man rather than from his animal origins, put human will and aspiration and effort first, and the terrestrial domain second—it is after all underneath our feet if we stand up—and the old premises which have clamped us down so long must vanish, and maybe a new birth will be given to a most ancient part of knowledge.

MARINE ANIMAL OILS OF CANADA

By Prof. T. P. Hilditch
University of Liverpool

THE varied and abundant fauna of the rivers of Canada and especially of the Atlantic and Pacific Oceans on the eastern and western shores of the Dominion form an important section of its natural resources. Canadian salmon, pilchard and cod are well-established edible commodities, but it is perhaps less widely known that in recent years the Canadian production of fatty oils from the flesh, livers, or other specific parts of certain fish and marine mammals has greatly expanded, whilst the quality of the oils is generally of a high standard owing to the increasing use of plant and conditions of extraction in accordance with the results of modern research on the chemical and technical properties of marine animal oils.

Up to the present the fish oils which have been most largely produced in Canada are from pilchards, herring, salmon, cod and halibut. Pilchard and salmon oils are extracted in quantity on the Canadian Pacific coasts, herring oil mainly on the Pacific, but also on the Atlantic shores, whilst halibut is taken from both oceans, and cod mainly but not entirely from the Atlantic side. The total annual fish-oil production of British Columbia varies from 2·5 to 4 million gallons per year, of which pilchard oil usually provides 1·5–2·5 million gallons; the Canadian annual production of cod liver oil of all grades is usually more than 150,000 gallons, although this is only 25–35 per cent of the amount of this oil produced in Newfoundland. There are, however, oils from a large number of other species of fish—coalfish, rockfish, rays, grayfish, ratfish and others as well as the more familiar ling, hake, mackerel or haddock—from which fatty oils could be produced in quantity. Again, more than 500,000 gallons of whale oil are made annually from whales taken off British Columbia; nearly half this output is from sperm or toothed whales, the rest from the baleen whales; seal oil is obtained in less amount (50,000–70,000 gallons per year) on the Atlantic coasts, and porpoise and dolphin oils, although not in much demand, could be obtained in quantity since these members of the Delphinidæ are plentiful off all the coasts of Canada.

Marine animal oils differ to quite a large extent in composition, although there are fundamental similarities in the kinds of fatty acids present in the form of glycerides or wax esters. Those of the cod or halibut liver, herring, salmon or baleen whale flesh, and many others are all comparatively similar, especially in containing major proportions of glycerides of highly unsaturated fatty acids with 20 or 22 carbon atoms in the molecule; but even in this group there are well-marked differences in the general proportions of the component fatty acids which seem to be mainly determined by species—perhaps also by dietary and other factors. Some of the other oils which have been mentioned differ more radically in chemical composition. Those of the sperm whales are largely wax esters and not esters of glycerol, the alcohols in combination with the mixture of fatty acids being largely cetyl, $C_{16}H_{33}(OH)$, and oleyl, $C_{18}H_{35}(OH)$. Ratfish liver oil seems to consist to a very large extent, not of glycerides, but of fatty acid esters of complex ethers of glycerol with a higher fatty alcohol. The Delphinidæ oils contain large amounts of *iso*-valeric acid in conjunction with the more usual kind of higher fatty acids, in the form of mixed triglycerides. It is natural that such variation in composition should afford scope for a variety of technical uses.

Probably, however, the most interesting of the fish oils at present are those which are found to be exceptionally rich in the fat-soluble vitamins. Halibut liver oil and, still more, the visceral oil, are well known in this connexion, but this is by no means the only instance. The production of exceptionally vitamin-rich fish oils, which serve as a valuable source of vitamin-A concentrates for incorporation in edible fats, is one of the most important fish-oil industries to-day. Although unsuitable *per se* for margarine or soap manufacture (by reason of odour and of proneness to atmospheric oxidation), fish oils and, more particularly, baleen whale oils, are converted by hydrogenation into more stable fats of high quality. But a number of other uses have been found for these oils, some of which may be less familiar. In contrast to their nutritional values, fish oils and their soaps find considerable use as toxic agents in insecticides, especially in fruit growing; the applications of these oils in the leather and textile industries are probably better known than the growing use of hydrogenated fish oils in the manufacture of tinplate; they can be transformed into rubber substitutes as well as into varnishes or linoleum.

The wide range of utility of the marine animal oils, potential as well as actual, is extremely thoroughly covered in a recent Bulletin edited by Dr. Brocklesby*; but the work can be commended for other reasons which will appeal to readers of NATURE. Instead of being limited to the purely technical aspects, the discussion of the latter is based entirely upon the fundamental chemical and physical properties of the fats, which are dealt with so adequately that the book forms a remarkably complete guide to the chemistry of fats as a whole. Moreover, the component acids and glycerides of the marine animal oils are considered in the light of modern research in this field (to which the chemists of the Pacific Fisheries Experimental Station have made their own contributions) and not solely with reference to the technically useful, but otherwise often uninformative, 'analytical characteristics' such as iodine values, specific gravities, etc.

The late Sir William Hardy, first director of Food Investigation of the Department of Scientific and Industrial Research, planned that the work in his research stations should involve equally the technical applications of science and the fundamental principles underlying these applications—a tradition which is still followed by the Food Investigation Board. It is evident that the balance between 'pure' and 'applied' science is similarly maintained by the Canadian Fisheries Research Board; in consequence the monograph now published will be read with as much interest and benefit by other scientific workers as by the technologists for whom it is primarily intended.

ELECTRIC HEATING OF BEEHIVES

THE British Electrical and Allied Industries Research Association has issued a preliminary report, by its director and secretary, Mr. E. B. Wedmore, describing experiments on the heating of beehives*. It also describes the construction and preliminary testing of certain units for keeping beehives at any required temperature. Tests are to be made shortly at the Rothamsted Experimental Station under working conditions on a large scale.

In Nature, the heat required by a colony of bees is produced by the consumption of honey. This is an expensive fuel, and might be helped out and controlled to advantage by the use of electricity. Many observations of temperatures within the hive in relation to the life and requirements of the bee have been made, and the craft has turned in the direction of controlled heating of hives. The aim of the present report is to bring the problem into perspective and to record some preliminary observations on effects within the hive of changing external temperatures and conditions, and of the use of certain heating units.

In obtaining figures of convenient magnitude, and in considering electric heating, it is convenient to measure all energy in electrical terms. The complete combustion of 1 lb. of an average honey with an average water content represents two watts for one month, and honey in the hive may be taken as being worth 6*d*. per lb. (If removed, extracted, strained, bottled, packed and carted, it may be worth, say, 1*s*. 4*d*. wholesale.) Thus the production of heat by the complete combustion of honey costs 3*d*. per watt per month if the efficiency is 100 per cent. The heat is, in fact, produced by the bees deliberately performing mechanical work, and while the oxygenation is probably fairly complete, there is wear and tear to be made good as well as shortening of the bees' life, so that the actual cost per watt per month to the beekeeper must be higher, but most probably less than twice 3*d*.

If sugar is used, the heat of combustion is about doubled, but if reduced to syrup by adding water, this additional water content has to be dealt with. The physiological loss is greater and the syrup has to be prepared. Taking the sugar syrup at 6*d*. per lb. of sugar including labour and wastage in storing, the cost per watt per month will be between 1½*d*. and 3*d*., not allowing for maintenance of and interest on the cost of apparatus.

Electrical energy could be substituted for honey consumption only if the heat be provided at the right time, the right place and in the right quantity. Assuming 100 per cent efficiency in each case, we have then for the cost of 1 watt per month: (*a*) by consumption of honey in the hive at 6*d*. per lb., 3*d*.: (*b*) by consumption of sugar in the hive at 4*d*. per per lb., 1½*d*.; (*c*) by use of electrical energy at 1*d*. per unit, ¾*d*. It is clear, therefore, that there must be some definite additional indirect gain if heating by electricity is to be justified, the cost of the equipment must be low and the technique of its use simple and efficient.

With the commencement of frosts in October, breeding is greatly reduced, and it ceases in December or earlier. Bardenbacher's tests suggest that brood raising may be advanced about three weeks by appropriate heating in the spring season, and one such advanced colony may well do the work of two. It is pointed out that in spring there are good hopes of stimulating brood raising by making it easier for the bees to maintain the requisite temperature, especially at night and in cold periods, and at the same time reduce the indirect losses caused by condensation of moisture.

Data as to the thermal properties of a hive and its contents are given. The hives are usually constructed of cedar or firs of varying quality, and some are painted. Probably reduction of forced movement of air within the hive in really cold weather by guarding the entrance is more important than any external packing.

---

* British Electrical and Allied Industries Research Association Technical Report, Reference W/T5: Electric Heating of Beehives—Preliminary Report. By E. B. Wedmore. Pp. 19+5 plates. (London: British Electrical and Allied Industries Research Association, 1941.) 3*s*. 6*d*.

To obtain currents of 1–20 watts from a 230-volt circuit requires resistances which, if wire-wound and suitably insulated, are relatively costly. On the other hand, two miniature lamps of suitable rating in series will give results of the right order at a moderate cost with reasonable life, and will admit of wiring a number of hives in parallel off a mained loop from hive to hive.

The hive used for preliminary experimental work consisted of a standard National body on a base with deep cover, a 6-in. lift being used to carry the heating units and packing so that the deep cover just overlapped the top of the body box. The hive was located in a well-ventilated wooden shed to protect it from winds. In certain tests a small fan was used to blow a stream of air at a speed of about 12 m.p.h. diagonally at the entrance. The hive used represents roughly the minimum size of stock hive that would be employed for wintering in Great Britain.

It has been shown that a small increase in the difference between the internal and external temperatures of the hive has a useful effect in reducing condensation and consequent dampness. Two periods have to be considered, namely, the quiescent period and the early brood-raising period. The useful applications already made belong to the early brood-raising period; the difficulties met with are mainly difficulties of control.

Twenty-four heating units are being built for Rothamsted Experimental Station, where they will be used with and without thermostatic control during next winter.

FORTHCOMING EVENTS

Monday, May 5

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. G. Stafford Whitby: "Chemotherapy", II.

British Psychological Society (at 55 Russell Square, London, W.C.1), at 1.20 p.m.—Mrs. Winifred Raphael: "War-Time Grouses in Industry".

Thursday, May 8

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 2.30 p.m.—Prof. S. Chapman, F.R.S.: "Electrical Works by Helios, or The Sun and the Ionosphere".

Friday, May 9

Geologists' Association (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. C. E. N. Bromehead: "The Early History of Mining".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Teacher of Engineering Workshop Practice and/or Woodwork and Drawing, and a Teacher of Mathematics and Science, at the Mexborough Schofield Technical Institute—The Secretary to the Managers, Education Office, Mexborough, Yorks. (May 10).

Senior Assistant Master to teach Science and Mathematics at the Sparkhill Commercial School—The Chief Education Officer, Higher Education Department, Education Offices, Council House, Margaret Street, Birmingham 3 (May 12).

Principal of the Shrewsbury Technical College—The Secretary, for Education, County Buildings, Shrewsbury (May 21).

Professor of Mechanical Engineering—The Registrar, University of Sydney, Sydney, N.W.S., Australia (June 1).

SCIENCE IN MODERN LIFE

DR. J. B. CONANT's address at the meeting of the Royal Society which followed a luncheon in his honour on March 20 added one more to the many utterances, among which Dr. Raymond B. Fosdick's review of the Rockefeller Foundation in 1939 is specially notable, indicating how clearly scientific workers in the English-speaking democracies have appreciated the seriousness of the threat to science and all other cultural and spiritual values of our civilization in Nazi power and philosophy.

It is true that, as President Roosevelt has said, unless we win there will be no freedom for either management or labour. The ultimate stakes are freedom of speech and expression, freedom of worship, freedom from wrong, freedom from fear. By winning we strengthen their meaning, increase the structure of mankind and strengthen the dignity of human life.

The struggle, however, no less than the reconstruction to follow, will demand some sacrifice of privileges until success is achieved. Restraints must be accepted for the service of security, the improvement of standards of healthful living and the provision of markets for manufacture and agriculture. In peace, as in war, clear and resolute thinking is required to determine the limits which can wisely be accepted without detriment to that creative thought, that fearless, disinterested search for truth upon which man's real progress always depends.

It is at this point in the relations of science and society that there is a decided clash between two schools of thought which has tended to darken counsel. The supreme importance of freedom of thought, of teaching and of investigation if science is to advance or even exist, and if creative minds are to be brought to bear on the solution of the many problems confronting mankind or to express in fresh forms the aspiration of man's spirit, is not doubted by those who stand together in the struggle against Nazi tyranny. It is no service, however, to that cause, to refuse to recognize, as Prof. M. Polyani and others do, that science itself is to some extent a social activity, the direction and extent of which are determined at least in part by the society in which the man of science finds himself.

Recognition of this fact, which has recently been ably argued in a pamphlet, "Science and Socialism", issued by the University Labour Federation, is fundamental to any constructive attempt to remedy the present position, or indeed ultimately to scientific advance itself. We have here one main and sufficient reason for the keen interest and sympathy of men of science everywhere in the struggle against domination to which the British Commonwealth is committed. They at least have been quick to recognize that the control of man over Nature, the making of the machine the servant and not the master of mankind, and that the "world of increasing hope and enjoyment for the common man, the world of honoured tradition and expanding science", of which Mr. Churchill has spoken, are not to be had in a world dominated by totalitarian tyranny of any form.

To maintain to-day the isolation of science from the problems of life, whether of war, of unemployment, of disease and poverty is as absurd as to maintain the mutual independence of electricity and magnetism. We must at least attempt to think dialectically about the relations of science with society if science itself is to exert its full creative and productive powers, still more if society is to attain that higher level of living and of civilization which scientific advance has already made possible.

To recognize, however, that science changes its social environment and is itself modified by that environment, that the extent of scientific resources and the direction in which they are used are dependent on the nature and outlook of the society in which the man of science works, is quite another matter from admitting the right of external authority to intervene in the quest for truth, enlarging the knowledge of the universe, which is of the essence of science. Scientific workers may not be able to obtain adequate support for carrying out a particular investigation unless they have succeeded in making its purpose sufficiently intelligible to enlist the sympathy of those controlling public funds. Their work is to that extent conditioned by the general outlook and culture of the community. It is another matter altogether if the community through its leaders or representatives should attempt to dictate the methods to be used and the results to be obtained in the investigation.

This is the point which is commonly overlooked by so many who have recognized the reaction of society on science. Their enthusiasm for the different position which, on paper at least, science and the scientific worker occupy in the U.S.S.R., sometimes betrays them into uncritical adulation of that position. "Science and Socialism", referred to above, is no exception. The planned control of scientific research does indeed imply that science is a concern of the State and establish the existence of a social function of science. It affords further evidence of the exiguousness of the distinction between 'pure' and 'applied' science. It emphasizes the need for every citizen to approach the problems of life with a scientific outlook.

To maintain further, however, that in such a society there is no distinction between the professional man of science and the layman is at once to incur the charge which Prof. Polyani brings against any totalitarian régime in the "Contempt of Freedom". There is no peculiar 'holiness' in science, and they do it a disservice who assert that science is something mysterious which cannot be comprehended by the ordinary citizen. To eliminate jargon and promote the effective exposition of what science is doing is one of the first duties of the man of science and one of the greatest safeguards of freedom of thought in a democratic society.

Scientific workers must admit the reactions on the direction and extent of their work which are imposed by the nature of the society in which they live. They can co-operate with their fellow citizens to widen those bounds and minimize any restraints. They can themselves seek to direct their work to serve the needs of society, the purposes of the community of which they are members. They can, however, in no wise admit the direction of their work by any external authority.

It is this allegiance and this clash of loyalties that is overlooked and obscured by so many writers of 'left' views. The danger of a totalitarian regime to scientific work and freedom does not depend on whether that regime is Communist or Fascist in political thought. The scientific worker's first allegiance is to truth itself, and his first duty to his fellow men the defence of feedom of thought and investigation and utterance. On that point there can be no compromise, and any support he may give to the furtherance of a political programme must not be inconsistent with that allegiance.

"Science and Socialism" betrays an obtuseness on this point no less lamentable than that of the Polyani school to the idea of planning. Scientific workers as a body are only too anxious to see society enjoying the higher standard of living, the ampler leisure and richer culture which science has made possible and to co-operate in the establishment of such an order. Their support cannot be given as implying unconditionable alignment with any political system or party. They must retain their freedom of thought and judgment. The scientific attitude cannot be abandoned even if it conflicts with an official social philosophy.

It can be readily admitted that there are many things to be redressed in the present order of society and that scientific advance itself has directed attention to such weaknesses. A capitalist society, however, has no monopoly of weaknesses and scientific investigation might equally lead to exposures calling for drastic reform under a socialist or any other conceivable order of society. The scientific worker cannot pledge himself in advance to keep silence as the price of support from any political party or system. He is first and foremost a servant of truth and bound to follow wherever she leads.

It is indeed possible that that loyalty might well lead scientific workers to a fairly general support of many tendencies generally regarded as socialist but for the excess which characterizes the statements of socialist propagandists as in "Science and Socialism". They have indeed no inherent objection to the planning of science, but whether that is done by men of science alone or in co-operation with others there are real difficulties. Mannheim's "Man and Society in an Age of Reconstruction" remains the outstanding contribution to the evolution of a type of planning in which democratic control could be maintained by institutional safeguards.

The continuance of scientific advance and the very existence of civilized society depend on the establishment of an ordered society in place of the anarchy and *laisser-faire* of the last twenty years. That in itself implies some measure of planning, and the urgent task to which scientific workers must make their own contribution is that of determining the conditions and technique by which we can advance to a higher form of freedom involving social co-operation and the maintenance of individual vitality and initiative in a planned society. This task will call for creative thought, for the steady widening of the fields in which scientific thought and method are brought to bear —an experimental attitude in social affairs and a readiness to learn from the lessons of history, which are far more characteristic of a democratic than of any type of totalitarian regime. Scientific workers can only make that contribution by clearing their minds fearlessly from all prejudices and preconceived ideas and by refusing to allow their loyalty to truth to be compromised by any support which they may, in the defence of freedom or the establishment of order and the furtherance of reconstruction, be called upon to give to a political party or institution. They must learn the art of co-operation with their fellow citizens, of interpretation and exposition, of spreading a scientific outlook and approach to the problems of society and of world order, abandoning all claims to be a class apart, without surrendering that higher loyalty which bids them follow wherever truth may lead them.

MIGRATION

Migration to and from the British Isles

Problems and Policies. By R. S. Walshaw. (Issued under the auspices of the School of Social Sciences and Administration in the University of Liverpool.) Pp. 94. (London: Jonathan Cape, Ltd., 1941.) 5*s*. net.

During the course of the present War population problems necessarily recede into the background. In a violent life and death struggle for our very existence as a nation, we do not need to consider, as immediately applying to our war effort, those interesting questions of births and deaths and migration which produce their effects over long periods of time. They have their grave importance in normal times, and they have had their cumulative effect in putting our man-power exactly where it is. If we were obliged—which God forbid—to contemplate a succession of gigantic world-wars, then the whole population structure would have to be studied with the single view of providing men for the services and for munition production, allowing only a minimum of those ineffective members of society who are chiefly to be found among the aged.

Mr. Walshaw's excellent little book is issued under the auspices of the School of Social Sciences and Administration in the University of Liverpool. The introduction is by Mr. Caradog Jones, reader in social statistics in that University, who rightly remarks that when peace comes again there will probably be an increase of public interest in migration questions. To show how such questions can affect even our war effort, we may quote his statement that the Dominions "are only ready to welcome the strong, the skilled, the intelligent." If such a drain of our best elements were to continue for any length of time, it is clear that the ultimate population would be less able to wage a successful war.

It is not always realized how large the drain has been in the past. Thus, during the nine years from 1905 until 1913 inclusive, the average net annual outward migration, from the United Kingdom, was 183,000; and even after the War of 1914–18 the average net annual outward migration for the six years 1921 until 1926, inclusive, was 120,000.

We all know how the birth-rate has been falling in Great Britain, and that the population, in spite of appearances, is not reproducing itself. Various estimates have been made as to the year in which we shall reach a stationary condition of population, and, as a rough guide, it may be said that if there had been no war, that condition would have been reached sometime about 1950. Now that we are at war we must expect that stage to be reached sooner. The author points out that, when we have reached a state in which there will be a natural decrease, in place of the increase to which we are accustomed, "the subject of external migration will begin to occupy a far more important place in the public mind than it does now."

One of the chapters deals with the ebb and flow of British migration to and from the continent of Europe, and it is stated that of the British in Europe in the year 1930, half were resident in France. "During the sixteen years 1922 to 1937 British immigration into the United Kingdom from Europe amounted to as many as 233,000 people". By the end of 1937 very few British subjects remained on the Continent, and one can read this with a certain sense of relief; though to counterbalance this we must remember that 67,000 British subjects are in the hands of the Germans, in the oldest part of the Empire, namely, the Channel Islands.

The most important matter discussed by the author is British migration to and from the Dominions, and he mentions the significant fact that, for the first time in our history, in 1931 we gained in population by inward migration. Most of those who came back were recent settlers who had failed to establish themselves and were stranded when the great depression arrived. With regard to the general question of migration to the Dominions, certain principles have been accepted by all the Governments concerned. It was, for example, agreed that a better distribution of the white population of the Empire is desirable, and that emigration required constant co-operation between the home and oversea authorities, and that full use should be made of the agency of such bodies as the Salvation Army, the Y.M.C.A., and so on. But the whole complex matter deserves study in the book before us, and Mr. Walshaw sets out clearly the various changes of policy and circumstance. A few matters stand out: thus, the Dominions have made it clear that they cannot absorb additional secondary producers unless there is a large increase in the number of primary producers.

On the question of the numerical effect of emigration from Great Britain, the author makes the following statement, which would seem to be incorrect: "In the British Isles . . . even after allowing for the losses of the war [of 1914–18], the cessation of emigration caused the population to be over a million more than it would have been had the pre-war trend continued". Actually it is easy to show that, if there had been no war, the population of Great Britain would have been some two millions greater than it actually was, as shown by the census of 1921.

It may be remembered that, at the International Population Congress, which was held in Paris in 1937, Prof. A. M. Carr-Saunders and Mr. Walshaw contributed a paper on recent population movements in Ireland, which raised the question as to whether the population of Great Britain was not likely, if present tendencies continued, to be eventually of predominantly Irish descent. Mr. Caradog Jones says in the introduction to this book, "Men accustomed to town life have been encouraged to settle in countries where the primary need is for workers on the land, their places being taken by countrymen from Southern Ireland". Mr. Walshaw remarks that "In view of the unimpeded influx of Southern Irish citizens into Great Britain . . . expenditure by the United Kingdom on the transference of its own citizens to the Dominions would already appear somewhat anomalous".

The question deserves impartial and objective study. To begin with, we must realize that southern Ireland is a small country and that the number of migrants that it sends out, nowadays, does not reach the huge proportions of the past. Southern Ireland uses emigration as a safety-valve, and its population remains nearly constant, with a tendency to decrease; between 1924 and 1936 the average excess of births over deaths was about 17,000 a year. The census of 1936 gave the population as 2,968,000, a diminution of 3,500 since 1926.

If we consult the figures of the census of Great Britain of 1931, we shall find that there were resident in Great Britain at that time, 359,163 persons who were born in southern Ireland; of these, 55,487 were living in Scotland. Taking the population of Great Britain in 1931 as practically 45 millions, it will be seen that the percentage of persons born in southern Ireland was 0·8. Of course, to those born in southern Ireland we should add those of Irish parents but born in Great Britain. There are indirect ways of getting at this figure, but not very exact. Perhaps the southern Irish now living in Great Britain might amount to 4 per cent of the whole population. There is some reason to suppose that this stock breeds rather more rapidly than the British stock.

As to quality, a large number of Irishmen who migrate to Great Britain find employment on heavy labouring work, but more than half the immigrants were women. The author thinks that some, at least, of the male immigrants are above the average in physical capacity. In the post-war world, this particular population problem should be studied attentively. Meanwhile, if the southern Irish now living in Great Britain throw in their lot whole-heartedly with the rest of us, during this period of the War, so critical for them as well as for us, we shall have no cause to complain.

EDUCATIONAL WORK IN THE UNITED STATES

(1) Educational Yearbook of the International Institute of Teachers College, Columbia University, 1940

Edited by Prof. I. L. Kandel. Pp. xiii+397. (New York: Columbia University, 1940.) 3.70 dollars.

(2) Student Teaching

An Experience Program. By Raleigh Schorling. (McGraw-Hill Series in Education.) Pp. xiii+329+33 plates. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 17*s.* 6*d.*

(3) Psychology in Education

By Herbert Sorenson. (McGraw-Hill Series in Education.) Pp. xiv+489. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 19*s.*

(1) THE determination of the English-speaking peoples to maintain educational thought and practice at a high level, even in the present distracted times, is illustrated by these three books from the United States. The first of them is the seventeenth annual issue (1940) of the well-known "Educational Yearbook", devoted on this occasion to problems of adult education. On this subject, profoundly important to democracy, the yearbook enables us to compare notes, not only with the United States, but also with the British Commonwealth of Nations, and with many other countries. One is not suprised to learn, however, that the editor found it "unfortunately impossible to secure articles from Soviet Russia and Nazi Germany".

The articles on Denmark and the Netherlands were written before the great devastation, and may still be taken, so far as they go, to represent the real mind of these stricken lands. As to England, it is here placed on record that adult education has been deemed far too important for maintaining the morale of the nation to be allowed to languish.

One of the general impressions left by a perusal of this comprehensive yearbook is that no definition of what is meant by adult education is yet possible. It may mean anything from courses at the university level to what the editor rather grandly calls "the liquidation of illiteracy"; that is, teaching people to read. Another clear impression conveyed by these reports is that sound adult education must come in response to the felt needs of the people, and from nowhere else. It cannot come by way of formal organization provided from above. "It is most successful and vigorous when it is spontaneous and springs from a desire to learn and an interest in self-education". At first sight it is strange to find that for adult education at its best we have to look to usually laggard England rather than to Scotland or the United States. This is partly due to the far greater provision for university education in these two countries, but partly also, we believe, to causes more creditable to England.

A remarkable fact, of special interest to readers of NATURE, is that even in English adult education there is only a slight demand for courses in science. Why, it may well be asked, should students in classes arranged by the Workers' Educational Association show such an overwhelming desire for social and literary subjects as to throw science definitely into the shade, notwithstanding the immensely important contribution of science to modern civilization? Even the relatively few science courses that are asked for are mostly elementary, and do not involve any serious scientific discipline. The report in the yearbook explains the fact by "the failure on the part of scientists to make clear the humane aspects of scientific study", and the inability of scientific specialists "to interpret their subject to others who are not specialists like themselves". But the recent provision of "mathematics for the million" is perhaps one sign among many that science is recovering its voice.

I am not sure, however, that this is the only way, or even the really effective way, in which science can be made to appeal to the more intelligent classes of the community. Men of science must, I think, address themselves to the task of breaking down the barrier set up last century between science and the humanities. It is not merely a question of making science easier to grasp, but a question of showing that science truly so called is from end to end as human as anything can be. The task will not be easy, for since the industrial revolution science has bestowed upon us not only marvellous benefits, but also an amount of noise, smoke and greasy dirt which apparently makes the W.E.A. student willing to forget science awhile, with all its works and ways.

(2) The breaking down of the old barrier between the scientific and the humane is exemplified in the work entitled "Student Teaching", a recent addition to the excellent McGraw-Hill Series in Education. The book is meant for students preparing to become teachers. Two generations ago, a similar book, whether British or American, would have contained no trace of the precision

which we associate with scientific method. A generation ago—*experto crede*—traces of that method began to appear. In the present volume the scientific method is well to the fore, chiefly in the form of statistics, charts, and "check-lists", some of which, by the way, would seem to most English teachers embarrassingly personal. The reader is supposed to be almost as well acquainted with intelligence quotients as with the multiplication table; but he is warned against accepting both as of equal validity.

Of course there is little that is of real scientific value in all these devices, but they do suggest that in pedagogy the scientific attitude has come to stay. Yet the author has written a rather jolly book, furnished with telling illustrations, and everywhere suggesting that a teacher deals with live children and not with laboratory abstractions.

(3) A further addition to the McGraw Series takes for its theme education as psychology sees it, there being few fundamental problems in education which do not find a place in Dr. Sorenson's book. They include the problems of growth and development, emotional reactions, behaviour, capacity to learn and the best methods of learning, measuring and marking achievement, and the forces of heredity and environment. The author adheres to no one school of psychology. He is, however, a thorough modernist. He represents in the main the new psychology of experiment, not the old psychology of introspection.

Dr. Sorenson's book provides a good example of the scientific humanism for which I would plead. It is to be hoped that the book will become known in Britain. Finally, I should like to see more evidence that the best British work in educational psychology (for example, that of Prof. Cyril Burt) is known in the United States.

T. RAYMONT.

CONTRASTS IN FIRST-YEAR GEOLOGY

(1) Introduction to Geology

General Geology, by Dr. E. B. Bailey; Palæontology, by Dr. J. Weir. Pp. xii+498. (London: Macmillan and Co., Ltd., 1939.) 18*s*.

(2) Geology

Principles and Processes, by Prof. William H. Emmons, Prof. George A. Thiel, Prof. Clinton R. Stauffer, Prof. Ira S. Allison. Second edition. Pp. xii+451. (New York and London: McGraw-Hill Book Co., Inc., 1939.) 21*s*.

A SUBJECT of such wide scope as geology cannot be presented fully in a first-year university course, and the difficult problem of selection must therefore be solved by lecturers in the way most appropriate to the needs of their students. The two first-year text-books under review are examples of solutions so extreme that neither is likely to correspond very closely with average requirements. The first covers an unusually broad field and deals with minerals, rocks, structures and map-reading, crystallography and microscopical petrography, physical geology, palæontology and historical geology. The second, by a group of authors, three of whom are at the University of Minnesota, is restricted to a much more detailed account of the materials of the earth and of geological processes; earth history is omitted, except for a table of the main divisions and outstanding events of geological time.

(1) The "Introduction", for which Dr. E. B. Bailey is largely responsible, is based on the first-year lectures delivered at the University of Glasgow during the years of his professorship (1930–37). The chapters devoted to palæontology are written by Dr. J. Weir and make up a little more than a quarter of the book. Another colleague, Dr. W. J. McCallien, has contributed two-thirds of the numerous illustrations, all of which are line drawings. Most of these are clear and effective, but a few of the more complex subjects are not very satisfactorily portrayed.

It is disappointing to find that Bailey's treatment of his topics is of very uneven value, both in manner and matter. His style of writing is highly individual and informal: somewhat journalistic, often graphic and entertaining, generally easy to read, but all too often marred by colloquialisms and carelessness of phrase and definition. As an example of inconsequential writing, the following would be hard to beat: "In some of the interior States of America it is laid down by law that salt must be fed to cattle. The reason is that our blood and other juices are salt solutions" (p. 78). Another curious statement (p. 115) is that the simple chemical composition of ore minerals is responsible for their habit of occurring in veins. The definition of a volcano—"an accumulation of material brought to the surface in a molten condition or by hot explosive gases" (p. 225)—is quite inadequate. Is a bed of volcanic ash a volcano?

The treatment of crystallography is very unorthodox, and the author's intention to help the student introduces difficulties that should not normally arise. The fact that the Miller indices of a crystal face are proportional to the parameters divided by the respective intercepts is not stated. What can a student be expected to gather from the statement that "The biggest index of a face symbol shows the axis-end from which the face starts" (p. 139)? The attempt to elucidate optical properties is seriously confused by the innovation (p. 161) of referring to the extinction directions of any birefringent section as X-er and Z-er axes (instead of saying they are relatively 'fast' and 'slow'), irrespective of the orientation of the section or of its uniaxial or biaxial character. Moreover, there are several mistakes. The refractive index of individual sections of a mineral in a rock slice is said to "range from zero to a definite maximum" (p. 162), and optic axes are said to be isotropic (p. 163).

The general liveliness of the book may be exemplified by the prophecies that much of the Yellowstone Park may be blown sky high within the next few thousand years (p. 76), but that during this time New York is not likely to be dangerously shaken by earthquakes (p. 244); and by the statement in a brief chapter on geophysical surveying that "A few good scientists believe that they possess the dowsing faculty". A particularly daring flight of fancy (p. 94) is that "What may be a single sill carries Stirling Castle, the Forth Bridge at Queensferry and long stretches of the Roman Wall in Northumberland (the Great Whin Sill of the North of England)". On p. 236 we read that "What is probably the same sill comes down to earth in the Lanarkshire coalfield". Actually, not even the 'Great Whin Sill' is a single sill.

In Part VII (pp. 381–479), which deals with historical geology, Bailey is at his best, and teachers and students alike will find this section both interesting and stimulating. This comment is equally true of Weir's highly competent survey of palæontology in Chapter v and Part VI. The biological aspects are much more thoroughly reviewed than in other elementary books and the student is systematically guided, with the aid of a profusion of admirably chosen illustrations, through the complexities of a subject that is here made much less forbidding than usual. The treatment is well balanced, vertebrates and plants receiving a full share of attention as well as invertebrates. Dr. Weir is to be congratulated on a presentation which is a model of its kind.

(2) The Minnesota "Geology" is the second edition of a text-book which first appeared in 1932. It has been revised, rearranged and completely reset, and in its now greatly improved form it becomes one of the best of the American books of similar scope. The first edition contained a chapter on earth history which has now been omitted, but other chapters have been expanded and new ones on sediments and igneous rocks introduced. There are also many new and original illustrations, by no means confined to subjects from North America, including beautifully reproduced photographs, well-designed block diagrams and other effective figures and maps, all of which add to the general appeal and educational value of the book. It was a happy thought to furnish many of the illustrations with inset maps showing unfamiliar localities. On the other hand, no locality at all is given for Welch's well-known photograph of a pothole in Glenariff (Fig. 137), which, moreover, is said to be after R. S. Tarr. In a few other cases the failure to indicate the scale of an illustration reduces its value; for example, Fig. 164, an arresting and highly instructive view of folds in the ice of the Ross Barrier.

The treatment is clear throughout, and generally logical and systematic; precise data are presented whenever possible; and the text is attractively written. The chapters on the atmosphere, natural waters, and sediments are particularly well done, though river meanders—always a difficulty—are unduly neglected. The clear distinction between processes of external and internal origin is somewhat blurred by the introduction of a class of sediments of magmatic origin and by the use of the term metamorphism to include replacement by groundwaters.

The later chapters, dealing mainly with internal processes, fail to reach the high standard attained in the earlier part of the book and are relatively old-fashioned in outlook. Another surprisingly bad definition of a volcano appears. This time "a volcano is an opening in the earth's crust through which hot rocks are thrown out" (p. 285). Details are given of many volcanoes and their eruptions, but they are not presented so as to build up a scientific picture, and no reference is made to the heroic and illuminating work of Perret. On p. 319 basalt is given as the aphanitic equivalent of peridotite as well as of gabbro. Magma formation is wrongly ascribed to relief of pressure by faulting and folding (p. 320). The gneiss figured on p. 389, and referred to as an example of a rock formed by dynamic metamorphism, is obviously a migmatite. Mountain building and other earth movements are said to be probably due to earth shrinkage. Alternative hypotheses receive no mention, nor is there any discussion of the many difficulties that stand in the way of accepting the shrinkage hypothesis.

A chapter on "Probable Conditions within the Earth" deals with geomagnetism and evidence from isostasy and seismology, but makes no mention of the outstanding work of Vening Neinesz. The nickel ore of the Sudbury intrusion is still given as an example of magmatic segregation, despite the fact that it is now known to be of later introduction (p. 423). The selected bibliographies with which most of the chapters are furnished require considerable revision. Some of the standard works to which reference is made have appeared in later editions than those cited.

Defects of the sort mentioned above make one hesitate to recommend the book as a whole for general reading, but so much of it is admirable that it should certainly be given a place in every college library. With further improvements on the lines indicated, a third edition, which should certainly be called for in due course, might well take first place among elementary text-books on physical geology.

PROGRAMME FOR SOCIAL REFORM

Programme for Victory
A Collection of Essays prepared for the Fabian Society by Prof. Harold J. Laski, Harold Nicolson, Herbert Read, Prof. W. M. Macmillan, Ellen Wilkinson, G. D. H. Cole. Pp. vii+187. (London: George Routledge and Sons, Ltd., 1940.) 5*s*. net.

THE common element in these six lectures is the belief of all the authors that something called the 'old order' is gone for ever, and that the only issue of our time is the question what is to take its place. Broadly speaking, the old order was the world of unplanned production and distribution on one hand, and international anarchy on the other. All are convinced that planning has come to stay, and that the independent State, certainly the small independent State, has no future. What they are not so certain about is whether this planning will or will not be carried out at the expense of personal freedom; whether we shall plan for social equality or for the protection of privilege; and whether it is to be conquest or the voluntary coming together of peoples in free supra-national associations which is to put an end to the proud sovereignty of the nation-State. It is the choice between these alternatives that the authors are concerned to shape.

Beyond this the word 'programme' is something of a misnomer. For with one or two exceptions there are no very concrete proposals in these lectures. There are general principles, and there is a good deal of eloquence. Prof. Laski is the most definite. He does say explicitly that a programme of social reform must be put in hand while the War is on, if fine words about democracy are to carry conviction to our oppressed allies. He suggests that that programme should include the repeal of the Trade Disputes Act, the abolition of the household means test, better allowances to the sick, the injured and the aged, and an effort to rescue public education from the rack and ruin into which it has been allowed to dissolve.

Mr. Harold Nicolson on world government is by contrast studiously vague. He says that he has deliberately chosen this title in order to avoid getting embroiled in the prejudices associated with "League of Nations" or "Federal Union". This tactful avoidance of prejudice, however, results in his telling us nothing at all about the kind of world government that he envisages, except that it would be a "loose Federation" based upon the "free co-operation of all free peoples". What kind of powers this Federation is to have, how it is to be organized, over what geographical area its writ is to run—for answers to such precise questions as these the reader will turn to this distinguished diplomat in vain.

Perhaps the most fresh and stimulating of all the contributions is that in which Prof. Macmillan deals with the problem of the British Colonial Empire. The significant fact upon which this lays emphasis is not that the Colonial peoples have been shamefully exploited (although sometimes they have); but that they have so little to exploit. We did not reduce them from a state of paradisical bliss to their present plight of disease and poverty. Their standards were wretched enough before ever the whites came interfering; and the great needs are, and always have been, money for development and for civilized services of all kinds.

In the remaining papers Mr. Herbert Read expresses fears lest a bureaucratic socialist State should stifle the voice of free artistic expression; Miss Ellen Wilkinson demands social justice; and Mr. Cole sums up with a moving plea for a liberal socialism which will combine the values of nineteenth century democracy with the techniques of twentieth century economics.

With the general attitude of these authors there will be widespread sympathy and agreement. But the book is not a programme. It merely gives an urgent stimulus to the demand that a programme consistent with this attitude should be quickly and precisely formulated. BARBARA WOOTTON.

A Junior Biology

By Kenneth C. Sparrow. Pp. viii+187. (London: William Heinemann, Ltd., 1940.) 4*s*.

THIS book is designed to cover a scheme of work for the first two years (of a five-years course), thus leading up to the School Certificate years. In biology, of all subjects, it is extremely difficult to make a judicious selection of material which will provide a connected and correlated course; but the author has succeeded well. Yet, many teachers of biology would be ready to join issue with the author for considering seeds and seedlings and the development of young animals so early in the course. Though the logical thing to do, from the biological point of view, it is exceptionally difficult from the educational point of view, for children are not familiar with seeds and seedlings, neither are they with incubating eggs. They are, on the other hand, with mature plants and birds, and that is where many teachers would prefer to begin.

There are some attractive photographs in the book, but they seem to have been chosen too casually; for example, Fig. 5, entitled "A Typewriter", shows more of a sturdy youngster than the machine it is intended to illustrate; the compression ignition engine cannot convey anything to a reader of such tender years, neither can the two excellent photographs of the development of the chick; the diagram of a model of the lungs would convey more if two illustrations were given representing the two extreme positions; and it is always misleading to group several animals or plants together without indicating their relative sizes as is done in Fig. 29 where the octopus is indicated as being not much bigger than the snail.

The book is essentially practical in outlook, which is all to the good. It should satisfy those teachers who accept this type of course. The work is so designed as to stimulate the spirit of discovering things and finding out their meaning. This is very desirable since though it may be that the young reader will forget most facts stated in the book, he ought to leave it with a real desire to discover things biological for himself.

Semimicro Qualitative Analysis

By William Lloyd Evans, Alfred Benjamin Garratt and Laurence Larkin Quill. Pp. vii + 246. (Boston, New York, Chicago and London: Ginn and Co., 1940.) 10*s*. 6*d*. net.

RECENT years have witnessed in inorganic chemistry the developments of a new technique involving analysis by semimicro methods, and the authors of "Semimicro Qualitative Analysis" have produced a most useful book for students in this field. A tremendous amount of detail, rendered more compact by an extensive system of abbreviations, has been compressed into this volume which includes five sections: an introduction describing apparatus, reagents and methods of procedure, one section each on the identification of cations and anions, a condensed outline of the theory of qualitative analysis, and finally a series of appendixes which is very comprehensive. The make-up of the book is somewhat novel in that it is of the loose-leaf variety, containing block outlines of methods, and flow sheets of experiments. It is therefore both a text-book and to some extent a laboratory note-book.

Semimicro analysis is not meant to displace the normal macroanalysis where larger quantities of materials are manipulated, but a course of this new technique supplies valuable training for a student since many of the rarer compounds are now, of necessity, analysed by micro methods.

The experimental details, which follow closely the better-known classical methods of analysis, are very clearly stated with ample explanations and directions. The theoretical part is couched in simple terms, but contains sufficient detail to enable the student to appreciate the methods employed in the experimental section. The appendixes will be found exceedingly useful since they contain much detailed instruction on the preparation of reagents, care of apparatus, general reactions of groups together with the usual tables of constants and lists of elements and symbols.

A course of microanalysis is almost essential now to aspiring chemists, and to such students this volume can be recommended with confidence as an indispensable item of their equipment.

Practical Pharmaceutical Chemistry

By F. N. Appleyard and Dr. C. G. Lyons. Fourth edition. Pp. vii+174. (London: Sir Isaac Pitman and Sons, Ltd., 1939.). 6*s*. 6*d*. net.

THE fact that this text-book by Appleyard and Lyons has made its fourth appearance in ten years is sufficient evidence of its popularity. This new edition differs from its predecessors only by a slightly expanded chapter on qualitative organic analysis.

Since this work is intended for those students entering for the Chemist and Druggist Qualifying Examination, it is not exhaustive, in that the work necessary for the Preliminary Scientific Examination is only reviewed briefly. Instead attention is focused on more advanced topics. At the same time adequate instructions and explanations are given of the principles underlying analyses of pharmaceutical products, particularly volumetric analysis.

The fact that the experimental details are condensed to fit in with a special curriculum probably accounts for the fact that some of the sections, for example, those on the assay of alkaloids and on permissible adulterants, appear rather short. In those sections and in the chapters on gasometric and gravimetric methods, the authors have obviously selected specimen examples to illustrate the technique required. The sections on organic preparations and organic qualitative analysis are very well done, and the field covered should prove adequate for the purpose of pharmaceutical students.

The practical work described in the text-book forms a suitable complement to the theoretical studies necessary in this course. Undoubtedly this new issue will maintain the high popularity earned by previous editions.

CARBON DIOXIDE ASSIMILATION IN HETEROTROPHIC ORGANISMS

BY DR. H. A. KREBS,
THE DEPARTMENT OF BIOCHEMISTRY, UNIVERSITY OF SHEFFIELD

BEFORE 1936, only autotrophic organisms—plants and a small group of bacteria—were known to assimilate carbon dioxide. Recent experiments have shown that carbon dioxide is also assimilated by many heterotrophic cells, including animal tissues. Although this reaction provides no more than a small fraction of the total carbon requirements of heterotrophes, it is of great interest, for it is one of the metabolic processes which is indispensable for the normal life of animal tissues, bacteria and moulds.

CARBON DIOXIDE ASSIMILATION IN PROPIONIC ACID BACTERIA

In 1936 Wood and Werkman[1], studying the fermentation of glycerol by propionic acid bacteria, made the unexpected observation that the end-products of the fermentation—mainly propionic and succinic acids—contained more carbon than had been added in the form of glycerol. Since the medium contained calcium carbonate (to neutralize the acids formed during the fermentation) the authors suspected that this might have provided the excess of carbon. In fact less carbonate was recovered than was originally present, and the authors thought it justifiable to conclude that propionic acid bacteria are able to utilize carbonate or carbon dioxide and to convert it into an organic compound. In 1938, Wood and Werkman[2] showed that the quantities of carbon dioxide used, and of succinic acid formed, are approximately equimolar. The experimental data conform with the assumption that there are two main reactions when glycerol is anaerobically fermented, namely :

$$(1)\quad \underset{\text{(glycerol)}}{CH_2OH.CHOH.CH_2OH} \longrightarrow \underset{\text{(propionic acid)}}{COOH.CH_2.CH_3} + H_2O$$

$$(2)\quad \underset{\text{(glycerol)}}{CH_2OH.CHOH.CH_2OH} + CO_2 \longrightarrow \underset{\text{(succinic acid)}}{COOH.CH_2.CH_2.COOH} + H_2O$$

Some of the intermediate stages of reaction (2) are outlined by the following scheme of Wood and Werkman[2,3] :

(3) 
$$(3)\quad \begin{array}{c} CH_2OH \\ | \\ CHOH \\ | \\ CH_2OH \\ \\ \text{(glycerol)} \end{array} \xrightarrow{-4H} \begin{array}{c} CH_3 \\ | \\ CO \\ | \\ COOH \\ \\ \text{(pyruvic acid)} \end{array} \xrightarrow{+CO_2} \begin{array}{c} COOH \\ | \\ CH_2 \\ | \\ CO \\ | \\ COOH \\ \text{(oxaloacetic acid)} \end{array} \xrightarrow{+2H} \begin{array}{c} COOH \\ | \\ CH_2 \\ | \\ CH(OH) \\ | \\ COOH \\ \text{(}l\text{-malic acid)} \end{array} \xrightarrow{-H_2O} \begin{array}{c} COOH \\ | \\ CH \\ \| \\ CH \\ | \\ COOH \\ \text{(fumaric acid)} \end{array} \xrightarrow{+2H} \begin{array}{c} COOH \\ | \\ CH_2 \\ | \\ CH_2 \\ | \\ COOH \\ \text{(succinic) acid)} \end{array}$$

According to this scheme pyruvic acid is the intermediate which actually fixes the carbon dioxide. The primary product of the fixation reaction is oxaloacetic acid ; this afterwards undergoes reduction to succinic acid.

Scheme (3) is now supported by three independent sets of observations :

1. The utilized carbon is present in the carboxyl group of succinic acid. This was shown by Wood, Werkman, Hemingway and Nier[4] with the help of carbon dioxide containing the heavy isotope ^{13}C.
2. Fumaric and malic acids, the postulated precursors of succinic acid, can be detected in the medium[5]. This applies to anaerobic conditions where succinic acid cannot be converted into fumaric and malic acids. Scheme (3) is the simplest, and therefore the most satisfactory, explanation for the simultaneous formation of the three dicarboxylic acids.
3. Added oxaloacetic, fumaric and l-malic acids are readily reduced to succinic acid as expected according to (3)[5].

It is probable that the assimilation of carbon dioxide by way of reaction (3) occurs in many other bacteria, although *B. coli* is so far the only other micro-organism for which the absorption of carbon dioxide has been directly demonstrated[4,6,7]. The occurrence of reaction (3) in other bacteria is indicated by the fact that they, too, form succinic acid from carbohydrate, glycerol or pyruvic acid. The evidence favours the view that the succinic acid is formed in these cases in the same way as in propionic acid bacteria, namely, through reaction (3). Experimentally, there is an important difference between propionic acid bacteria and other organisms ; in the latter the (assumed) uptake of carbon dioxide is counterbalanced by the simultaneous production of carbon dioxide ; carbon isotopes are therefore the only means of obtaining direct proof of the carbon dioxide fixation. The special position of propionic acid bacteria is due to the fact that from these organisms side reactions producing carbon dioxide are absent when glycerol is fermented.

CARBON DIOXIDE ASSIMILATION IN ANIMAL TISSUES

The discovery of carbon dioxide assimilation in animal tissues arose from a study of the fate of pyruvic acid in pigeon liver. This tissue is capable of synthesizing a 5-carbon chain from the 3-carbon compound pyruvate. Glutamine ($CONH_2.CH_2.CH_2.CHNH_2.COOH$) is formed from ammonium pyruvate[8], α-ketoglutaric acid ($COOH.CH_2.CH_2.CO.COOH$) from sodium pyruvate[9]. α-Ketoglutaric acid is very probably an intermediate in the synthesis of glutamine. The synthesis of α-ketoglutaric acid was found always to be accompanied by a synthesis of malic acid[7]. This observation provided the clue to the mechanism of the reactions taking place in the presence of pyruvic acid. Since α-ketoglutaric acid is known to undergo an oxidation to succinic acid and afterwards to malic acid, the simultaneous formation of α-ketoglutaric and malic acids might be expected if sufficient oxygen is available. However, a detailed investigation of the conditions under which α-ketoglutaric and malic acids were formed made it clear that the bulk of the malic acid could not have been formed by the oxidative breakdown of α-ketoglutaric acid. Thus the conclusion had to be drawn that a synthesis of malic acid from pyruvic acid takes place in addition to the synthesis of α-ketoglutaric acid.

When this was first observed[7] it was already known[10] that α-ketoglutaric and malic acids arise simultaneously when oxaloacetic acid is added to animal tissues. The following anaerobic reactions occur in the presence of oxaloacetic acid[10].

(4) oxaloacetic acid $\longrightarrow$ pyruvic acid + CO_2
(5) oxaloacetic acid + pyruvic acid $\rightarrow$ citric acid + CO_2
(6) citric acid $\longrightarrow$ α-ketoglutaric acid + CO_2
(7) oxaloacetic acid $\longrightarrow$ $l(-)$ malic acid

When oxygen is absent the reactions (5) and (6), which are oxidative, are each coupled with the reductive reaction (7), and the net effect of (4), (5), (6) and (7) is thus:

(8) 4 oxaloacetic acid $\rightarrow$ α-ketoglutaric acid + 2 malic acid + $3CO_2$

Since pyruvic acid yields α-ketoglutaric and malic acids in somewhat similar proportions the simultaneous synthesis of α-ketoglutaric and malic acids from pyruvic acid may be explained by the assumption that oxaloacetic acid is formed first from pyruvic acid and carbon dioxide:

$$(9)\quad COOH.CO.CH_3 + CO_2 \longrightarrow COOH.CO.CH_2.COOH$$

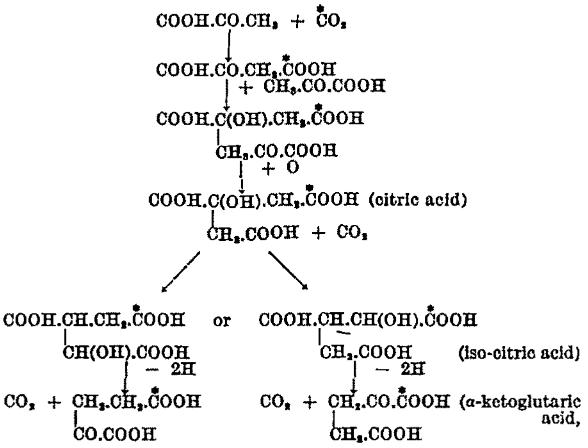
or

$$COOH.CO.CH_3 + H_2CO_3 \xrightarrow{-H_2O} COOH.CO.CH_2.COOH$$

and that this reaction, the 'carboxylation' of pyruvic acid, is followed by reaction (8). All the experimental results agreed with this assumption. Moreover, the rate of pyruvic acid disappearance was found to depend on the carbon dioxide pressure and this supported the view that carbon dioxide takes part in the metabolism of pyruvic acid.

SCHEME SHOWING THE FATE OF ASSIMILATED CARBON DIOXIDE IN PIGEON LIVER

(The carbon atom introduced in the form of CO_2 is marked with an asterisk. If a carbon isotope is used, two different forms of iso-citric and α-ketoglutaric acids both containing the isotope are formed.)



Yet the evidence could not be regarded as conclusive so long as the absorption of carbon dioxide had not been directly demonstrated. In living tissues there are always metabolic processes in which carbon dioxide is produced, and these more than counterbalance the carbon dioxide uptake. In the balance sheet there is, therefore, a production of carbon dioxide. The use of carbon isotopes is the obvious method of tackling this problem. If carbon dioxide containing an isotope is used, the α-ketoglutaric acid synthesized from pyruvic acid should contain the isotope, if the mechanism suggested by the reactions (8) and (9) is correct (see the accompanying scheme). The decisive experiment was carried out by Evans and Slotin[11]. They used carbon dioxide containing the radioactive ^{11}C and found that α-ketoglutaric acid, as expected, contained radioactive carbon. This result completes the proof of the occurrence of reaction (9) in pigeon liver.

EFFECT OF VITAMIN B_1 IN ANIMAL TISSUES

The rate of pyruvate utilization is much reduced in the liver of pigeons suffering from severe beri-beri, and addition of the vitamin restores the normal level of pyruvate removal[7]. This holds for conditions under which the synthesis of oxaloacetate from pyruvate and carbon dioxide is the chief reaction responsible for the removal of pyruvate and it may therefore be concluded that the 'carboxylation' of pyruvate is dependent on vitamin B_1. Since the carboxylation might involve more than one step—for example, a phosphorylation of pyruvate followed by the actual condensation with carbon dioxide—it remains to be investigated for which particular step of the carboxylation the vitamin is required.

Barron and Lyman[12] assume that vitamin B_1 is a general coenzyme of pyruvate which takes part in a number of different reactions of pyruvate. There are, however, important arguments in favour of the view that the vitamin is a specific catalyst of the actual carboxylation and that it is directly concerned with the formation of the C-C linkage. The vitamin has no effect on the rate of pyruvate removal in the *muscle* of B_1 deficient pigeons[7], and this indicates that the vitamin is not a 'general' coenzyme of pyruvate. A second argument is based on the principle of enzyme specificity and on what is known about the action of vitamin B_1 in yeast. In yeast[13] vitamin B_1 (in the form of its pyrophosphate ester combined with a specific protein) catalyses the conversion of pyruvate into acetaldehyde and carbon dioxide :

$$(10)\quad CH_3.CO.COOH = CH_3.CHO + CO_2$$

This reaction also occurs in moulds, plants and certain bacteria but is absent from animal tissues. The action of the vitamin in animal tissues must, therefore, be different from that in yeast. At the same time it is certain (Peters[14]) that here, too, the vitamin is concerned with the metabolism of pyruvate. Furthermore it is highly probable, in view of the high specificity of enzymes in general, that the reaction of pyruvate in animal tissues is analogous to (10). It has been suggested that this analogous reaction might be the "oxidative decarboxylation" of pyruvate leading to acetate and carbon dioxide :

$$(11)\quad CH_3.CO.COOH \xrightarrow{+\ O} CH_3.COOH + CO_2$$

But as we know of no biological catalyst capable of catalysing an oxidation in one case, and a non-oxidative reaction in another, it is difficult to regard the catalytic mechanisms of (10) and (11) as analogous. The carboxylation of pyruvate, on the other hand, is analogous to (10) : both reactions are non-oxidative, both involve a C-C linkage, and in both carbon dioxide is a reactant. They differ in that an α-ketonic acid is involved in (10) and a β-ketonic acid in (9) and in that (9), a carboxylation, is the reverse of (10), a decarboxylation. From the point of view of enzyme chemistry these differences are not fundamental, for it is known that one and the same catalyst can decarboxylate α-ketonic acids as well as β-ketonic acids[7] and that enzymic processes are reversible. The analogy between (9) and (10) is in these circumstances a very weighty argument in favour of the view that vitamin B_1 is specifically concerned with reaction (9).

The facts so far known do not make it necessary to assume that the vitamin catalyses other reactions in animal tissues, but it is by no means improbable that this is the case. McHenry[15] has shown that vitamin B_1 is necessary for the synthesis of fat in the intact organism. Since this is a complex process dependent on the supply of energy, the effect of the vitamin may be indirect ; but it is also possible that a condensation analogous to (9) in which carbon dioxide is replaced by a carboxylic acid, occurs in the synthesis of fatty acids and is directly catalysed by the vitamin.

EFFECT OF VITAMIN B_1 IN BACTERIA

In staphylococci, vitamin B_1 is known to be required for the 'dismutation' of pyruvate :

$$(12)\quad 2\ \text{pyruvate} \xrightarrow{+\ H_2O} \text{lactate} + \text{acetate} + CO_2$$

This was shown in a striking experiment by Hills who found that the rate of the dismutation is much reduced in staphylococci grown in a vitamin B_1 deficient medium and restored to the normal level by added vitamin[16].

If the function of vitamin B_1 in staphylococci is the same as in pigeon liver, that is, to bring about the synthesis of oxaloacetate, it should be possible to replace vitamin B_1 in Hills' experiment by oxaloacetate. Smyth[17] has shown that this is the case. In vitamin deficient staphylococci, oxaloacetate restores—temporarily—the normal rate of pyruvate dismutation. Oxaloacetate has no effect on "vitamin sufficient" cells. These facts are all explained if we assume that the vitamin acts by forming oxaloacetate from pyruvate.

It is not at once clear how the formation of oxaloacetate is connected with reaction (12). If the presence of oxaloacetate influences the rate of dismutation, as it does, the latter must be more complicated than the scheme (12) suggests. A satisfactory explanation of the oxaloacetate effect is afforded by the assumption that oxaloacetate participates in the dismutation. From what is known about the metabolism of oxaloacetate in other organisms, it is probable that oxaloacetate acts as a hydrogen carrier in the manner indicated by the following scheme :

$$(13)\quad \text{pyruvate} + \text{oxaloacetate} \xrightarrow{+\ H_2O} \text{acetate} + CO_2 + \text{malate}$$

$$(14)\quad \text{malate} + \text{pyruvate} \longrightarrow \text{oxaloacetate} + \text{lactate}$$

The net effect of these two reactions is (12). This hypothesis is supported by several experimental observations : the reduction of oxaloacetate to malate, and the oxidation of malate to oxaloacetate, postulated by the hypothesis, have been found to occur. Malate, moreover, has the same effect as oxaloacetate in vitamin deficient cells[17].

Biological Significance of Carbon Dioxide Assimilation in Heterotrophic Organisms

The significance of the carbon dioxide assimilation through reaction (9) obviously depends on the biological significance of the oxaloacetate formed by this reaction. So far two important functions of oxaloacetate are known. One of them, hydrogen transport in respiration, has already been mentioned. A second function is that of a parent substance of a number of essential cell constituents.

Hydrogen transport by oxaloacetate was first discovered in 1935 by Szent-Györgyi[18]. He observed that oxaloacetate is rapidly reduced to malate in respiring muscle tissue and that malate can undergo rapid re-oxidation to oxaloacetate. The system

$$\text{oxaloacetate} \underset{-\,2\text{H}}{\overset{+\,2\text{H}}{\rightleftharpoons}} \text{malate}$$

is now known to be an essential link in the respiration of many, if not all, animal tissues and also of a number of bacteria.

As a parent substance oxaloacetate takes part in the synthesis in animal tissues of a series of organic acids—citric, α-ketoglutaric, succinic, fumaric, malic acids—and of at least two amino acids, glutamic and aspartic acids and their respective amides, glutamine and asparagine.

Carbon Dioxide as a Growth Factor

Favourable effects of carbon dioxide on the growth of micro-organisms have been known since the work of Bang[19] in 1897, but early investigators believed that the effect of carbon dioxide was rather indirect, for example, by replacing oxygen and thus lowering the oxygen tension. More recently it has become clear that the effect is direct and specific. It has been found in numerous micro-organisms.

The widespread occurrence of the carbon dioxide effect may be taken to indicate that carbon dioxide takes part in some fundamental metabolic process, common to many organisms. The synthesis of oxaloacetate is a reaction sufficiently fundamental to offer an explanation for the necessity of carbon dioxide. This hypothesis can be experimentally tested. If it is correct, it should be possible to replace carbon dioxide by malate, or fumarate, or asparagine, or other substances which can serve as a source of oxaloacetate.

Carbon Dioxide and Anaerobiosis

The fact that air inhibits, or prevents, the growth of "anaerobes" can in many cases be explained by a simple chemical theory[20]: anaerobes lack the enzymic catalase, but at the same time they possess enzymes which cause molecular oxygen to react with the hydrogen of substrates. The end-product of this reaction is hydrogen peroxide. The latter oxidizes, and thus destroys, vital cell constituents.

The absence of catalase, however, does not account for *all* the inhibitory effects of 'air' on bacterial growth. Propionic acid bacteria (with the exception of one species) contain a powerful catalase. Yet these organisms grow poorly on the surface of agar, whilst growth is abundant in the deeper layers of agar stab cultures where the conditions are semi-anaerobic. Werkman and Brown[21] go so far as to call propionic acid bacteria 'anaerobes'. Van Niel[22] speaks of a "strong tendency towards anaerobiosis".

In a stab culture of a carbon dioxide producing bacterium the pressure of carbon dioxide will be greater inside the agar gel than on its surface, and it is in some cases feasible that the differences in surface and stab growth are due to these differences in the carbon dioxide pressure. It is easy to demonstrate that this view is correct in the case of propionic acid bacteria: the differences in surface and stab growth disappear when the cultures are kept in an atmosphere containing 5 per cent or more carbon dioxide. Under these conditions the organism grows readily on the surface of agar. Theobald Smith[23] carried out similar experiments on *Brucella abortus* as early as 1924.

The work reviewed in this article shows that carbon dioxide is an active metabolite in heterotrophic cells. It can condense with pyruvic acid to form oxaloacetic acid. By this reaction carbon dioxide is 'assimilated'. Oxaloacetic acid has at least two important functions in cell life; it acts as a hydrogen carrier in the energy-giving processes and is a parent substance of a number of cell constituents. Of special interest is the fact that the condensation of pyruvic acid with carbon dioxide depends on vitamin B_1.

THE USES OF PSYCHOLOGY IN WAR-TIME

BY DR. C. S. MYERS, C.B.E., F.R.S.

PSYCHOLOGY and three of its applied branches —medical, educational and industrial psychology—have made enormous strides since the War of 1914–18. In 1914 these branches were in their infancy; to-day they may be said to have passed their adolescence. Indeed, industrial psychology has so widely developed that the term has become a misnomer. It is now concerned with all occupations, and (in developing vocational guidance) even with pre-occupational life: it should be styled 'occupational psychology'. In 1914 tests of intelligence were only just coming into general use in the medical and educational worlds. Now they are officially recognized by the Ministry of Health, the Board of Education and the Board of Control.

MEDICAL PSYCHOLOGY

In 1914 our present attitude towards the psychoneuroses ('functional' nervous disorders) and their treatment was only just developing. To-day that attitude is approaching stabilization, with maturer experience and the mellowing and blending of certain early crudities of the rival Austrian, French, German and Swiss schools. During the early years of the War of 1914–18 a 'shell-shocked' soldier wandering from his post in a psychoneurotic fugue (or trance) was regarded by Army disciplinarians either as a deserter fit only to be shot for his crime or as a madman certifiable as insane and destined for a lunatic asylum. But by the end of 1916 special hospitals for the reception of cases of war-neurosis and for their psychological treatment by medical specialists had been established in France, both at British bases and in army areas; and similar provision, together with special courses of training for medical officers, was being made at home.

Some of the many lessons learnt have not been forgotten during the present War, although so far the occurrence of war-neuroses has been comparatively rare. To each Army Command throughout Great Britain at the outbreak of war medico-psychological specialists were appointed, acting under a War Office consultant; and a special military hospital was established. A corresponding system was provided for the British Expeditionary Force, and by the Ministry of Health for civilians and soldiers. Intelligence tests, administered by psychologists, are now being officially employed to prevent the retention of men suffering from, or near the border-line of, mental deficiency. The recruitment of men so dull as to make it difficult for them to become satisfactory soldiers has always been a serious problem in war-time. It is especially grave to-day with the increased pace of modern warfare and with the greater skill demanded by a mechanized army. Advice has also been sought by the Admiralty from psychologists during the present War on the improvement of methods for the rejection of the colour-blind.

AVIATION PROBLEMS

The psychological laboratories of two British universities are now engaged in research on individual differences in the speed and degree of adaptation of the eye to darkness—a problem of especial concern to the Royal Air Force. For the same fighting service research is also being conducted on other psychological problems of flying, for example, on the kinds of error to which the pilot is most liable when subject to the stress and fatigue occasioned by prolonged periods of flying 'blind'. Other experiments having a war-time reference are also being carried out in psychological laboratories, for example, concerning methods of communication and concerning the effects of certain drugs and other chemical substances on mental efficiency.

VOCATIONAL GUIDANCE AND SELECTION

I well remember visiting one of our most distinguished mathematicians during the last War at Boulogne in 1915. I found him sorting and counting railway tickets in a small cabin in the marshalling yard of the harbour station! It took some time before his outstanding abilities were utilized in solving the problem of gunnery range-finding. To-day more systematic efforts are being made to avoid such errors of placement. All three of our fighting services are beginning to avail themselves of the psychological principles and methods of vocational guidance and selection which have been developed with increasing success during the past twenty years in choosing the best job for a given applicant and in choosing the best applicant for a given job. Throughout the various commands, army officers are now being trained by civilian psychologists in the application of some of these methods to recruits, so as to help in their selection for commissioned and non-commissioned rank and for special work (for example, driving or gunnery), and to reveal recruits of very low intelligence, within the various arms to which they have already been allocated. This scheme may be usefully extended to recruits *before* their allocation, to men, no longer recruits, who need transfer from work (for example, tank or pioneer) to which they have already been unsuitably allocated, and to the better selection and allocation of officers. To improve present methods, the War Office has recently appointed a small advisory committee of psychologists. The Royal Air Force is, correspondingly, employing civilian psychologists with the object of sorting out recruits already allocated to its air-staff; the psychological problems of selection of its ground-staff have as yet scarcely been touched. Tests have also been applied to naval units, and the Admiralty has lately invited a vocational psychologist to survey and to report on its present methods of education.

Several local investigations of a less official and less centralized character have also been carried out by psychologists at the request of army officers specially interested in the grading of recruits and their distribution to specialized work. For example, tests have been devised on behalf of a tank brigade for gunnery and for driving efficiency. The commander of an artillery regiment has invited psychologists to test the intelligence of his recruits, and has used the results to help in selecting such specialists as gun position officers' assistants, range-takers, etc. The intelligence has been tested of large batches of recruits in the Royal Army Medical Corps, whose scores were found to range from 0 to 94 (the maximum possible score being 100); the object of this inquiry being to assist in the classification of recruits and in their selection for special duties demanding a fairly high level of intelligence, including the work of instructors and of non-commissioned officers, and, in the case of the most 'backward' recruits, for an appropriate course of special instruction. At the request of a War Office directorate, the best methods of choosing instructors in a certain kind of technical work have been psychologically investigated; and certain recommendations have been adopted. All such work should lend no support to the current popular fallacy that the psychological methods employed in vocational guidance and selection consist solely in the application of tests. These are, in fact, merely accessories to other systematic methods based on psychological principles. They are invaluable servants, but must never be the masters, of the vocational psychologist.

TRAINING

During recent years the attention of certain industrial psychologists in Great Britain has been directed to improvements in methods of training. In most factories the novice has hitherto learnt his job and still learns it by passively watching a more expert operative, by listening to such words of explanation and advice as the latter may be willing or able to give while engaged on ordinary production work, and by 'trial and error' during subsequent routine practice. But the industrial psychologist now insists that training must be isolated as far as possible from production; that a 'school' for novices must be separately established; that the instructor must be most carefully selected; and that the course of training must be systematically planned. He urges this procedure because the expert operative cannot teach satisfactorily while busily engaged on production, and because he often proves a bad teacher, unable to describe what movements he uses or why he uses them, or even believing that he employs certain movements whereas actually he employs others. For the course of systematic instruction installed by the industrial psychologist, the easiest movements and the most advantageous position of parts and tools must have been previously determined. These are demonstrated and taught to the novice, and the reasons for adopting them must be carefully explained to him. As a beginner, he is taught always to inspect his products; and a 'museum of faults' is placed on exhibition, from which he may learn what errors he is likely to commit, how they may be avoided and how, if they do occur, they may best be dealt with.

These new methods of instruction have produced surprisingly good results. Not only have they enormously shortened the period of training, but they have also vastly improved the efficiency of the novices thus trained. They have proved of especial industrial value in war-time, when, as in many engineering works, unskilled persons are necessarily being engaged to take the place of semi-skilled workers who have had to be transferred to more highly skilled work. With appropriate modifications they appear to be also applicable to certain kinds of military training. But so far, in this connexion, during the present War, psychologists have been mainly employed by the fighting services in devising apparatus which will improve and facilitate training, and in addressing officers on the general principles of the subject, at training centres. Books and articles have also been published on the psychological factors involved in leadership, in propaganda work and in the causation of war.

WORKING CONDITIONS

Industrial psychology has afforded valuable help to firms engaged on Government contracts, in regard to the arrangement of shifts and the distribution of hours of work and rest-pauses, especially when, at the outset of war, excessive working hours were being urged. It has also helped to solve the difficulties of factory lighting and ventilation caused by the 'black-out', which resulted in unusual fatigue, absenteeism and higher labour turnover. For the Red Cross Society and Order of St. John of Jerusalem, an investigation in industrial psychology has been conducted into the easier packing and handling of parcels destined for prisoners of war.

SOCIAL CONDITIONS

Several systematic studies have been and are being conducted by educational and social psychologists on the effects on children of evacuation and air-raids; and other psychological investigations of similar, but wider, social import, under the ægis of one of the Ministries, can be reported.

This account does not by any means exhaust all the services that psychology is giving during the War. But it may serve to show the growing and increasingly recognized military, medical and social, practical value of the subject.

LA SOCIÉTÉ DE PHYSIQUE ET D'HISTOIRE NATURELLE DE GENÈVE

BY PROF. F. E. WEISS, F.R.S.

GENEVA has long been renowned as the home of eminent men of science. Some of these, the de Saussures and the de Candolles, belonged to families which, like the Darwins, have produced several generations of distinguished scientific men. It is no wonder, therefore, that the Physical and Natural History Society of Geneva has a deservedly high reputation, and that its *Memoirs* find a ready exchange with the publications of most learned societies. Last October the Society celebrated its hundred and fiftieth anniversary, and an account of the meeting of celebration fills the pages of the October number of its proceedings. The centenary celebration in 1890 was naturally made a great occasion and the centenary volume of the *Memoirs* of the Society contains a number of important scientific papers, as well as a history of the Society prepared by the secretary, Dr. A. H. Wartmann.

Like many learned societies, it had its origin in the desire of a number of men of various professions, but all interested in scientific discoveries, to meet and talk over their observations and theories. They met at first informally and probably at irregular intervals in each other's homes, and their number was for this reason naturally limited. For this reason also there seems to have been some doubt as to the exact time when the Society was founded. It really grew into existence. The first minutes of a meeting are dated August 5, 1791, but M. Vaucher, one of the originators of the Society, gives the date of its foundation as 1790, and this date has been by common consent accepted. No doubt even before that date the Society had an informal existence, for it possesses a manuscript which is said to have been read at one of its meetings in 1783. From the first minutes of a meeting mentioned above we learn that it met in the house of a M. H. A. Gosse, a pharmacist, and a laureate of the Paris Academy of Sciences. Among those present were L. Jurine, a surgeon and naturalist; J. Tallot, whose interests were geological; Pastor Jean Pierre Vaucher, head of a boarding-school and an eminent botanist, interested in freshwater Algæ, one of the most well-known of which has since been named after him. Other members who formed the nucleus of the Society, but who were absent from this first meeting, were M. A. Pictet, a lawyer and professor of philosophy, interested in physics and the applied sciences; Colladon, a pharmaceutical chemist, and the botanist Gaudy. This group of young amateurs, as Vaucher called them, was soon joined by other members of senior standing and already distinguished in various branches of science. They included H. B. de Saussure and his son Theodore, François Huber, well known for his researches on the life of bees, Pyramus de Candolle, the eminent botanist, and Henri Boissier, rector of the Academy and in charge of the instruction in applied botany. His natural history collection became the nucleus of the future National History Museum of Geneva.

It was decided to ask the veteran Charles Bonnet, then seventy-one years old, to become the honorary patron of the Society. This for reasons of health he refused. Being further pressed he accepted the position, but he died two years later, leaving a bequest to the Society.

Ordinary meetings of the Society still remained somewhat informal. The host at whose house the meeting was held presided and read a paper which was followed by a general discussion. Observations published in scientific journals were also discussed by the meeting. One of the original members tells us that the discussions were always amicable and that contributions by young members were welcomed and encouraged. Occasionally eminent men of science passing through Geneva were invited to the meetings. Such guests included Volta, Berthollet, Arago, Ampère, and others.

The strict religious tenets of the citizens of Geneva are reflected in the rules of the Society, one of which forbade any member or correspondent to admit publicly any religious principles that were not based on theism. Consequently the motto chosen for the Society was "Pro Deo et Natura".

In the early days of the Society—1792–1798—Geneva passed through stormy times, including a reign of terror in 1793 and ending in the annexation of Geneva by France in 1798. Except for an interruption of a few months in 1793, the Society continued its meetings, though they were occasionally prevented by untoward circumstances. When, after the restoration of Geneva to Switzerland, Pyramus de Candolle returned in 1817 as professor of natural history, he found the Society somewhat somnolent. He urged the institution of fortnightly instead of monthly meetings, and advised that the latter should be held in the lecture hall of the Society of Arts. This was done, and shortly afterwards it was decided to publish the *Memoirs* presented to the meetings, and up to date forty-one volumes have appeared containing 435 memoirs.

In 1890, when the centenary celebration of the Society took place ; it numbered 450 ordinary and 50 honorary members. The celebrations of the hundred and fiftieth anniversary which took place in October of last year, are described in a special number of the *Compte Rendu* of its meetings. They took place in the large hall of the Athenæum in the presence of some three hundred members, friends, and delegates from kindred Swiss societies. As the president, Mr. Revilliod, said in his opening address, with so much sorrow and misery in the world at large this was not the time to have great festivities, but it was deemed right to have a special meeting of the Society to remember the early days of its birth and growth and to honour its founders and the great men who contributed to its progress and prestige.

The subsequent speakers at the meeting included the Swiss Councillor for Public Instruction, the Rector of the University of Geneva, who dwelt on the close connexion between the University and the Society. This was emphasized by the subsequent addresses, in which three of the University professors dealt with the advances made in various sciences since the centenary celebrations of 1890. Prof. Weigel spoke of the progress achieved during the last fifty years in mathematics and physics. In connexion with the latter subject he dwelt on the important work done by Edward Sarasin and de la Rive in demonstrating the existence and the propagation of electromagnetic waves in space. The advances made by chemical researches in Geneva since 1890 were dealt with by Prof. Briner, while Prof. Fernand Chodat devoted his address to the progress of the biological sciences during the last fifty years.

The list of ordinary and honorary members of the Society elected between 1790 and 1940 follows the account of the meeting, and among the honorary members are the names of many British men of science, including Sir Joseph Hooker, Sir William Ramsay, Douglas Freshfield, and Sir Arthur Eddington.

OBITUARIES

The Right Hon. Lord Stamp, G.C.B., G.B.E., F.B.A.

LORD STAMP, Lady Stamp and the Hon. Wilfred Stamp were killed in a recent air attack on London. Lord Stamp was a man of whom many different obituary notices might be written. As a Civil Servant, as a business administrator, as a Government advisor and negotiator, as a writer on economic problems, he had so many achievements of distinction to his credit that adequate note of him in any one field crowds out reference to any other field. He worked as easily as ordinary mortals breathe or sleep. He could afford to say "yes" to innumerable invitations to speak or write on relatively unimportant occasions without losing power to do first-rate work on important occasions. His energy was incredible and his output superhuman. All this has been emphasized in one way or another by those who have paid tribute to his memory.

The branch of activity in which I came to know him best was different from any of those which I have named above. It was his activity in developing both the teaching of economics and research in it by others. In that field I learned what I believe to have been the central secret of his success and his public service.

Stamp was easily the most distinguished student produced by the London School of Economics and Political Science. He repaid his debt to the School many times over by the services which he rendered on the governing body from 1925, as vice-chairman of the governors from 1930 and, after the death of Sir Arthur Steel-Maitland in 1935, as chairman. In those positions his capacity and his prestige were of enormous assistance to an institution in a state of perpetual growth to meet an apparently inexhaustible demand. Growth implied both an external need for resources to feed it, and an internal need for adjustments to the changed scale and kind of activities. In solving the innumerable problems, external and internal, incidental to such growth and change, it was invaluable to have at hand a man of Stamp's humanity, justice and breadth of understanding. I remember well more than one question of policy or of important personal choice on which the power to rely upon him to come in and give judgment was of first-rate importance. His handling of problems was so transparently honest and so sympathetic to all the different arguments presented to him, that, however he decided any issue in dispute, those who were unsuccessful went away feeling little less happy than those who had succeeded. They were made able to feel, not that they had had a bad case, but that they had had a good case which had unfortunately encountered a rather better case on the other side. I have often felt, as so many others have felt, that if there was something affecting us which ought to be decided by someone other than ourselves, we would sooner have Stamp decide it than anyone else of our acquaintance. It was this gift of conciliation, of never quarrelling, even in disagreement, that made Stamp seem the indispensable person for so many important tasks of statesmanship and made him perform so well all those varied tasks.

William Beveridge.

Prof. Herbert Freundlich, For. Mem. R.S.

By the death of Herbert Freundlich in Minnesota on March 29 at the age of sixty-one, colloid science has lost one of its chief exponents. His remarkably comprehensive grasp of the literature of what had been up to his time a somewhat widely diffused collection of facts and *ad hoc* hypotheses permitted him to bring them into order and, indeed, into a logical system. His memory will long survive not only on account of his own contributions, but especially for "Kapillarchemie", his classical book on the subject, of which the fourth edition in two volumes appeared in 1930.

There are two predominant characteristics which we associate with Freundlich : the simplicity of his experimental technique, and his great influence as a teacher and inculcator of enthusiasm. It is a remarkable tribute to Freundlich that most of the important monographs on the specialized fields in colloid science which have appeared in the last twenty years have been written by authors who commenced their investigations with him. Whilst it is fairly customary for senior research men to spend some time in foreign universities, the particular piece of research work they carry out there is not often chosen as the main field of their future investigations, yet such was the case in the Dahlem Laboratory.

Freundlich's early work on colloid systems dealt with the preparation and coagulation of sols. Whilst this work covered much the same ground that Sir William Hardy had sketched out some years before, it led Freundlich to a more detailed examination of the various properties which sols can acquire in special circumstances. The general principles of the electric double layer had been laid down by Helmholtz and Smoluchowski : Freundlich was the first to show that the so-called electrokinetic (or Freundlich) potential was an entity distinct from the Nernst or thermodynamic potential, and by a series of important and interesting experiments he showed how variations in the electrokinetic potential and the concomitant change in colloid stability could be produced by the addition of electrolytes. He likewise examined and explained the mechanism of sensitization such as is noted in many biologically important systems and is readily demonstrated by the addition of albumin to a ferric oxide sol.

In 1923 Szegvary showed that a ferric oxide sol to which is added a suitable quantity of electrolyte sets to a gel which can be liquefied by shaking and resets to a lyogel on standing. This behaviour, termed 'thixotropy', was examined in detail by Freundlich, who showed that the same laws apply to thixotropic setting as in electrolytic coagulation, and that a variety of systems, including a number of great technical importance, such as the paints, can exhibit the phenomenon. In investigations which spread over many years, he showed that thixotropic systems are complementary to the dilatant systems of Osborn Reynolds, with a range of plasticity in between. The investigation of the phenomenon of streaming double refraction shown by sols of anisodimensional particles was another important investigation taken up with all the thoroughness and simplicity of experiment characteristic of Freundlich together with his co-worker, Zocher.

Among many other investigations initiated by Freundlich, the inquiry with Posnjak into the nature of swelling and the investigations on orientated adsorption in relation to catalytic activity must be mentioned as being especially interesting and suggestive. The adsorption isotherm, usually attributed to Freundlich, was in fact proposed and utilized by Boedeker and Wilhelm Ostwald, but Freundlich greatly extended its application, especially to capillary active solutions.

Freundlich was half British by birth ; he had many friends both in Great Britain and in the United States. Those of us who knew him well miss a colleague who was not only erudite, but also at the same time both extremely lively and interesting in conversation.

Eric K. Rideal.

I entered Freundlich's laboratory in Braunschweig, where he was professor on the Technische Hochschule, in 1911, working there and later in my own laboratory until the War of 1914–18. Shortly after the War, I translated his great work on colloid chemistry ; the second edition, about twice as long, has found no publisher in English. Freundlich in those days was very happily married to a beautiful *Rheinlaenderin* with the dark curly hair and blue eyes of the Celtic type so common in those parts. She was a brilliant pianist, as was Freundlich himself, for he had up to the age of nineteen pursued music as a career with the thoroughness and energy characteristic of his family. When he concluded that he would never be a great composer, he abandoned music for chemistry, success in anything but creative work being not good enough for him. His father was a Jewish manufacturer, his mother a Scotswoman, and the combination produced five sons of extraordinary but diverse abilities, Erwin, for example, having been the first astronomer to uphold Einstein's views.

The funds available to Freundlich for research were incredibly small—I believe about £60 annually. But he was one of those experimenters able to obtain fundamental results with the simplest means. His laboratory was one more example of the extraordinary fact that important work very frequently comes from badly equipped laboratories. He had an extraordinary aptitude for clearing up, by well-directed experiments linked with a critical examination of other results, groups of phenomena of the complicated type occurring in colloid chemistry. His later work in ultrasonics and thixotropy are examples of this.

Freundlich went to Dahlem in 1917, where for seventeen years he directed a large research school, and spent his happiest and most productive years. He left Germany (as a protest against Nazi interference with his choice of collaborators)—*schlagartig*—using, as he said, the Nazis' own slogan. He went to University College, London, taking his apparatus—a gift of the Rockefeller Foundation. But he was now a different man owing to a domestic bereavement rather than political persecution, which indeed he had only experienced in the persons of his assistants in Dahlem. For this reason, perhaps, his personality was much less appreciated than I had expected.

At the time of his leaving for the United States, Freundlich showed no signs of physical or mental enfeeblement. He is said to have died from a heart-attack, and he never took exercise. But he was a sparely built man, and in the Braunschweig days could walk many a sportsman off his feet when he chose. I sometimes wonder whether he did not take life "to heart" much more than ever he showed, and whether this last exile to an extremely trying climate may not have ended prematurely a life which might now be rendering Great Britain valuable services.

H. Stafford Hatfield.

Prof. E. F. Francis

Prof. E. F. Francis, who died on April 15, was a graduate of Victoria University (Liverpool) and of the University of Erlangen. He joined the staff of the Chemistry Department, University College, Bristol, in 1895, was appointed assistant professor in 1904 and became full professor in 1906. During this early period he played a very active part in the movement which led to the establishment of the University of Bristol, became a member of the first Council and impressed the mark of his personality on the institutions and organization of the new university. He was the second to fill the office of pro-vice-chancellor, which he held until his retirement in 1936, and during the period 1921–22, he was acting vice-chancellor. He became very well known in the city of Bristol and was largely instrumental in promoting the cordial relations which exist between the city and the university.

When he became professor in 1906, he took over the laboratories in the old building facing University Road, with two assistants and fifty students. On his retirement in 1936 the number of students had increased to more than two hundred and the teaching staff included two professors and nine lecturers. In 1908, he was responsible for the building of a new chemistry department, and with the able assistance of Dr. F. W. Rixon he supervised the building and equipment. This Department served as a model for other chemistry departments which were constructed in the years immediately following. He had a great sense of responsibility as to the function of a university professor in the training of the characters of his students. He established a school of physical chemistry at Bristol and with typical unselfishness he encouraged its growth at the expense of his own research school. On his retirement in 1936 his friends collected £2,500 for the endowment of a Francis Francis Scholarship for the encouragement of post-graduate work in chemistry.

Francis's researches, which were carried out in spite of heavy university duties, were very largely the work of his own hands. In some forty original communications to the learned societies, he covered a wide range of subjects in organic chemistry. He was interested in the condensation products between keto-derivatives and substituted anilines, the action of nitrosyl sulphide on organic substances, the catalytic decomposition of nitroso triacetonamine, which he employed for the estimation of hydroxyl ions, and other topics. He was especially interested in the preparation and properties of the long-chain carbon compounds. This interest first arose from his association with Prof. Sydney Young in joint publications in 1898 on the separation and oxidation of hydrocarbons. This led to a more extended research on the oxidation of paraffin wax which has aroused some attention as providing a possible means whereby waxes may be converted into fatty acids and thence to fats. In order to gain accurate knowledge of the materials composing paraffin wax, he studied the systematic building up of the longer hydrocarbon chains ranging from C_{18} to C_{46}. In the course of this work he has cleared up many obscure points in the chemistry of the natural fats and waxes. His advice was frequently sought and ungrudgingly given to other workers in this field. He set a very high standard in the purity of his products; his patience was inexhaustible, and he spared no pains in order to achieve this end. These products were employed in X-ray investigations, in measurements of heats of crystallization, dielectric constants, etc., which researches always received his enthusiastic encouragement. The standard he has set in this field of research will be difficult to surpass, although he was engaged up to within a few days of his death on an investigation which attempted to raise even his own high standards.

W. E. Garner.

NEWS AND VIEWS

Government Changes

IT was announced on May 1 that the King has been pleased to approve the following appointments: Minister of State, Lord Beaverbrook; Minister of Aircraft Production, Lieut.-Colonel J. T. C. Moore-Brabazon (see NATURE, **146**, 554; 1940: **147**, 344; 1941); Minister of Shipping and Minister of Transport, Mr. F. J. Leathers; Parliamentary Secretary, Ministry of Transport, Colonel J. J. Llewellin; Parliamentary Secretary, Ministry of Aircraft Production, Mr. Frederick Montague. The King has been pleased to approve that the dignity of a barony of the United Kingdom be conferred upon Mr. Leathers, and that Mr. Leathers and Colonel Llewellin be sworn of His Majesty's Most Honourable Privy Council. Mr. R. H. Cross, formerly Minister of Shipping, has been selected to fill the post of High Commissioner in the Commonwealth of Australia for His Majesty's Government in the United Kingdom. It is added that the amalgamation of the two Departments of Shipping and Transport for the purposes of the War will be effected forthwith. The details of this process will be worked out as speedily as possible and when the process is complete the combined Ministry will become the Ministry of War-time Communications.

Social and Technological Change

IN an article "Science in the Totalitarian State" in *Foreign Affairs* of January, W. Kaempffert points out that both Stalin and Hitler agree in requiring the university professor to serve the State, accept the tenets of the official ideology and eschew any excursions into the metaphysical or theoretical. In a totalitarian regime, the artist, man of science or philosopher must not only believe what he is told to believe by his rulers; he must also practise that belief. Objectivity is derided in both the Soviet Union and in Germany as unattainable and as anti-social. This insistence on the crushing of individuality assumes different aspects in the U.S.S.R. and in Germany because of different economic needs and social conditions, but Nazi and Soviet officials and professors go to incredible lengths in following their rules, and the totalitarian concept of the relation of science to the State is remarkably elastic. When political expediency so determines, the whole concept is modified and on the whole the pliancy of the scientific mind in both countries is remarkable.

Behind the ideologies of dictators and professional pliancy, however, Kaempffert suggests that there is more than political expediency, or blind obedience. Dissatisfaction with social structure may also be a factor. If the dictators are to be overthrown and democracy preserved, the part that science and technology have played in the rise of democracy cannot be ignored. Research results not only in change within science itself but also social change. The democratic method is to adapt social change to technological change. The dictators are trying to do the contrary. They have tried to control thinking, above all scientific thinking. Science is more than synthetic dyes or drugs, radio, aeroplanes, television —it is an attitude of mind. If Hitler, Mussolini and Stalin are to rule, the scientific attitude will have to be abandoned when it conflicts with the official social philosophy. If it is abandoned there can be no Newtons, Darwins, Einsteins. Science will be unable to make discoveries which will change the human outlook and with that outlook the social order. To preserve science as a powerful social force for good, the research physicist, chemist or biologist must be permitted to enjoy the fundamental freedom of democracy.

Marxists are right in maintaining that science has never achieved perfect objectivity. But there has been a brave, determined, continuous and on the whole successful effort to strip scientific investigation and theorizing of emotional and of personal predilections. Democracy flounders before it arrives at satisfactory solutions of its social problems, but it is better to flounder and progress than to follow the philosophy of a dictator and remain socially and scientifically static. Under a totalitarian regime science may indeed exist, but it will become frozen as art and science were in ancient Egypt.

The Carnegie Trust

THE thirty-ninth annual report of the Carnegie Trust for the Universities of Scotland covers the year 1939–40, and in addition to an abstract of the financial accounts for the year ending September 30, 1940, includes a summary of grants for the period October 1, 1940—September 30, 1941, reports upon the work of investigators under the research scheme during the year 1939–40, including a list of publications and summary of awards and payments as well as of the awards of fellowship, scholarships and grants under the research scheme, the report of the superintendent of the Laboratory of the Royal College of Physicians for the year 1939–40 with list of publications, and reports upon the work of Carnegie teaching fellows during the academic year 1939–40 with list of publications. Interim distributions for the year 1940–41 amounting to £50,760 have been allocated, or one-fifth of the quinquennial grant, attention being directed to the undesirability of proceeding with extensive building programmes. Of this £8,680 has been distributed to the University of St. Andrews, £13,800 to Glasgow, £9,200 to Aberdeen and £13,780 to Edinburgh with £5,300 to the extra-mural institutions. Of these sums £5,660 is to be expended on libraries, £39,850 for building and permanent equipment, and £5,250 for the endowment of teaching and general purposes.

Up to date, seven fellows and thirty scholars have intimated that their researches have been suspended on account of war service. Arrangements have again been made to keep the awards open for those now engaged on national duties so as to allow their researches to be resumed at a later date. Further, if a fellow or scholar has undertaken Government work within the universities, he is allowed by the Trust to do so subject to a certificate being obtained from the principal of the university for a fellow or from his supervisor for a scholar to the effect that the work is of that nature. Reference is made to work by Dr. Walter Tebrich under his fellowship in organic chemistry in collaboration with Dr. W. O. Kermack on compounds related to the sulphanilamide drugs, leading to many new pyridine and piperazine derivatives, and on the discovery of new antimalarials, involving syntheses in the benzcarbazole series. In connexion with grants to assist investigations in organic chemistry the report refers to work on derivatives, of acridone related to the sulphanilamide drugs, and to work on the polysaccharides of ribwort seeds and of Irish moss. The report of the superintendent of the Laboratory of the Royal College of Physicians, in addition to further reference to the work of Dr. Tebrich, also refers to other work on antimalarials carried out by Dr. A. P. Weatherhead and by Mr. W. Webster on the synthesis of phenanthroline compounds derived from *m*-phenylenediamine.

Zoos in War-time

The annual report of the Zoological Society of London, presented at the annual meeting on April 29, shows that, despite a drop of about half the income and attendance figures down to about a third of the normal gate, some two thousand animals have been maintained at Regent's Park, and it is intended to maintain the zoological collection until full activities can be resumed after the War. In 1940 seventy-eight mammals, including an onager, fifty-five birds, and twenty-four reptiles were bred at Regent's Park, and two Rheinhardt's argus pheasants have been reared. Damage from more than 120 fire and explosive bombs has been less than expected, only the rodent house and zebra and wild ass house being seriously damaged, and the young giraffe, 'Boxer', bred at Whipsnade, died of a dilated heart due to over-exertion caused by fright. A few antelopes died of damage caused by fright. Damage to the monkey hill, camel house, ravens' aviary, aquarium and north gate can be made good, while bomb craters at Whipsnade can be relined to serve as dew ponds. The work of the prosectorium is being continued, with the usual examination of blood parasites and bacterial flora, research on the protozoan and helminth parasites of fish, and the routine examination of animals for helminth ova to facilitate preventive measures.

The report of the North of England Zoological Society shows the increasing receipt of animals from other zoos like Bristol, Dudley and Edinburgh to its zoological gardens at Chester for the duration of the War, and of special war-time feeding successes, notably waste chicken heads for leopards and lions, horse-flesh for pelicans, and dried, crumbled stale bread for cranes and pheasants, porridge for sun bears. In the difficulty of losing its male keepers for the services, this Society has had disappointing results from the appointment of girl keepers. The griffin vulture was bred for the first time in Great Britain, and the young bird is now thriving: the adults laid again on March 19.

American Message to British Zoologists

American men of science are not forgetful of their colleagues in Great Britain, and many letters expressing interest in conditions in Great Britain tell of the concern they feel. The American Society of Zoologists has expressed its goodwill in the following cablegram, received by the President of the Association of British Zoologists (Prof. J. Ritchie): "The American Society of Zoologists recently in session at Philadelphia sends greetings and encouragement to its British colleagues. L. V. Domm, Secretary". Needless to say, British zoologists warmly appreciate this friendly message, and look forward to a reunion in Great Britain with their American friends when, as J. B. Priestley suggested, the streets shall be blazing with light and all the windows shall be illuminated—but not through the agency of incendiary bombs.

Agricultural Meteorology in India

A fairly detailed account of a year's research work in agricultural meteorology is to be found in the official annual report of the Agricultural Meteorological Section, India Meteorological Department, for the year, 1938–39 (Pp. vi + 48. Simla: Government of India Press, 1940). The Imperial Council of Agricultural Research again financed the section, although proposals for making the Section permanent were under consideration by the Government of India. The Central Agricultural Meteorological Observatory, which is situated in the grounds of the Agricultural College, Poona, extended the scope of its work. This was made possible through the gift of an additional plot of land to the Observatory by the College. Experiments were continued at the Observatory on the rate of ascent of moisture through typical soils and its rate of evaporation from their surfaces. A 30-ft. tower was erected on the new plot for the investigation of variations with height of wind, humidity and temperature. Instrumental development included the design of an instrument for measuring the amount of rain or irrigation water lost by evaporation and by percolation and that actually retained in those layers of the soil with which plants are concerned. A few instruments of this design were made and preliminary trials of them begun.

'Precision' observations for showing the effect of weather on certain crop yields were continued at Poona and Karjat, and trials of statistical methods of sampling for the estimation of crop yields were made. Statistical investigations were also continued of a number of other subjects which have particular importance for agriculture apart from their general meteorological interest, among them being that of the date and type of the onset of the south-west monsoon along the west coast of India and of the evidence for the influence of afforestation on climate in the Singhbhum District. A notable result of the Section's activity in liaison between meteorology and agriculture can be seen in Appendix I of this report, which is a long list of experimental farms at which meteorological instruments have been installed, with details of each lay-out.

Timber Utilization in Malaya

MALAYAN Forest Records No. 13 (Caxton Press, Ltd., Kuala Lumpur, 1940), by H. E. Desch and A. V. Thomas, is not intended to replace the standard text-books, but to provide local timber users with a minimum of information necessary for the correct use of Malayan timbers under Malayan conditions. The paper, which is fully illustrated, deals with the subject on the well-known lines of: anatomical structure of wood, identification and classification of Malayan timbers, seasoning, defects, preservation, mechanical properties of timber, and design in relation to correct utilization of timber in new buildings. The authors have commenced their work by giving an account of the forest administration, climatic factors, types of forest, timber resources and forest policy of Malaya, sylvicultural operations, timber requirements of the future, exploitation, methods of extraction, and financial aspects—somewhat unusual information to find incorporated in what is admittedly a handbook for timber users. The authors make a noteworthy admission. As a result of their investigations—and they have had predecessors in India—they state that in connexion with the tropical and semi-tropical forests it is not possible to draw a hard-and-fast line between the commercially productive and the protection forests; nor is it possible to calculate with any degree of accuracy the potential annual production of timber to be obtained from these types of virgin forest. The volumes per unit of area obtainable from the latter bear no relation to an equivalent area of commercial forest in temperate regions.

Protection of Buried Electrical Cables

IN the *Bell Laboratories Record* of January, Mr. R. P. Ashbaugh describes how the lead sheath of a buried electric cable can be protected against soil corrosion. These buried cables have been used extensively in rural areas instead of aerial cables for several years. In several localities in the United States, cases have frequently occurred where small rodents such as gophers have gnawed the cables, puncturing the sheath and so letting in moisture, which ruins the insulation. Two layers of substantial steel tape protect the cable conductors against inductive interference from power lines and also against gophers, but they are expensive, and a cheaper construction was therefore sought. The construction adopted consists of a single overlapping layer of impregnated paper, a single layer of thin steel tape applied helically with just sufficient gap to allow for normal bending, a second overlapping layer of impregnated paper, and one or two layers of impregnated jute roving. Floodings of asphalt compounds are applied over the sheath and over each protective layer of paper and jute. About 130 miles of this new construction has been furnished for the buried portion of the Stevens Point - Minneapolis cable, and a considerable number of small orders for territories that are gopher-infested have also been manufactured and installed.

The Stockholm Technical Museum

THE Tekniska Museet of Sweden has recently been installed in new buildings in Stockholm, erected with funds provided by the Knut and Alice Wallemburg Foundation. The Museum was originally opened in 1923, and it has been assisted by many industrial companies and private persons. In view of the important contributions to engineering, metallurgical and chemical progress by many eminent Swedes, the Museum should prove a worthy addition to such institutions. There will be a Hall of Fame and in this will be the busts of Polhem, Swedenborg, Celsius, Ångström, Rinman, John Ericsson, Carlund, Nobel, De Laval, Wenstrom, Brinell and others. An outstanding exhibit is an original tower clockwork shown running, designed and built by Polhem. It was moved to the Museum from St. Mary's Church in Stockholm, where it had been running from 1765 until 1910.

Vital Statistics of London County Council

THE interim report of the London County Council Medical Officer of Health and School Medical Officer for the year 1939 contains the following information: The residential population for the middle of 1939 was 4,013,800, as compared with 4,062,800 at the middle of 1938. The marriages registered in London during 1939 numbered approximately 54,461, or 27·1 persons married per thousand of the population. The live births allocated to London during 1939 were approximately 52,366, as compared with 54,495 in the previous year. The live birth-rate was 13·0 per thousand, the rate for 1938 being 13·4. The deaths in the total population of London during 1939 numbered 46,377, giving a death-rate of 12·3 per thousand, as compared with 11·4 in 1938. Of the total deaths 22,554, or 48·6 per cent, were among females. There was an increase in the number of fatal street accidents—from 363 in 1938 to 519 in 1939. The deaths under one year of age per thousand live births were 47, compared with 57 in the preceding year. This constitutes a new low record.

Dr. Heinrich Kisch

DR. ENOCH HEINRICH KISCH, an eminent balneologist and gynæcologist, was born on May 6, 1841, at Prague, where he received his medical education and qualified in 1862. In the following year he settled in Marienbad as a balneologist, and largely contributed to making that town a health resort. In 1867 he was appointed lecturer, and in 1884 extraordinary professor in balneotherapy, at the medical faculty of Prague. In 1868 he became editor of the *Allgemeine balneologische Zeitschrift*, and later of the *Jahrbücher* *für Balneologie*. His principal original works in balneology were "Handbuch der allgemeinen und speciellen Balneotherapie" (third edition, 1875) and "Grundriss der klinischen Balneotherapie" (1897), while his chief gynæcological publications, in order of their appearance, were "Über den Einfluss der Fettleibigkeit auf die weiblichen Sexualorgane" (1873), "Das klimakterische Ältern der Frau" (1874), "Die Sterilität des Weibes" (1895), and "Geschlechtsleben des Weibes in physiologischer, pathologischer und hygienischer Beziehung" (1904), which was translated into English by M. Cedar Paul in 1910 under the title of "The Sexual Life of Woman". An autobiographical work entitled "Erlebtes und Erstrebtes: Erinnerungen" appeared in 1914. He died at Marienbad on August 24, 1918.

Gustave Le Bon

DR. GUSTAVE LE BON, a prominent psychologist, ethnologist and natural philosopher, was born at Nogent Le Notru, Eure-et-Loire, on May 7, 1841. He started his career as a medical officer in the French Army and served in the Franco-Prussian War of 1870–71, but afterwards gave up the practice of medicine and travelled extensively in Europe, Africa and Asia. In 1884 he was ordered by the French Government to report on the Buddhist monuments in India. The results of his investigations were published in "La Civilisation de l'Inde" (1884) and "Les Monuments de l'Inde" (1894). He is best known, however, for his works on psychology, especially "La Psychologie des foules" (1895), which went through twenty-seven editions and was translated into many foreign languages. He also wrote on psychology in relation to the French Revolution, the War of 1914–18, socialism and education. His chief contributions to natural philosophy consisted in his "Évolution de la matière" (1905) and "Évolution des forces" (1907). An anatomical and mathematical study on variations in the size of the cranium won him a prize from the Paris Academy and the Anthropological Society of Paris. He was founder and for some years director of the Bibliothèque de philosophie scientifique. He died on December 14, 1931.

Announcements

PROF. A. V. HILL, M.P., one of the secretaries of the Royal Society, has been elected a foreign associate of the U.S. National Academy of Sciences.

AT a recent meeting of the official and family trustees of the British Museum, Cardinal Hinsley, Archbishop of Westminster, and Sir William Bragg, director of the Royal Institution, were elected to the Trust.

DR. E. L. KENNAWAY, of the Royal Cancer Hospital, London, and Dr. J. W. Cook, regius professor of chemistry in the University of Glasgow, have been awarded the annual Katherine Berkan Judd prize of a thousand dollars by the Memorial Hospital for the Treatment of Cancer and Allied Diseases, for outstanding contributions to the knowledge of the cause and cure of cancer during 1939 and 1940.

A DECREE depriving Mlle. Eve Curie of French citizenship and confiscating her property was signed by Marshal Pétain in Vichy on May 5.

AT the anniversary meeting of the members of the Royal Institution held on May 1, the following officers were elected: *President*, Lord Eustace Percy: *Treasurer*, Sir Robert Robertson; *Secretary*, Major Charles E. S. Phillips.

A NEW institute of hygiene and medical chemistry has recently been established at Göttingen.

AT the recent meeting of the Indian Science Congress at Benares, the Indian Society of Genetics and Plant Breeding was inaugurated. The following officers were elected for the year 1941: *President*, Rao Bahadur T. S. Venkatraman; *Vice-Presidents*, Dr. W. Burns, Mr. K. Ramiah; *Secretary*, Dr. B. P. Pal; *Treasurer*, Dr. S. Ramanujam; *Councillors*, Dr. V. K. Badami, Dr. B. S. Kadam, Dr. J. S. Patel, Dr. T. S. Sabnis. The Society will publish a journal in which papers on genetics, plant breeding and cytology will be published.

A MEETING for the inauguration of a Radiography Group of the Institute of Physics will be held at 6.0 p.m. on May 20, in the Lecture Hall of Messrs. Kodak, Ltd., Harrow. All who are interested in the uses of X-rays in industry, whether members of the Institute of Physics or not, are invited to attend.

THE following awards for 1940 of the Institution of Mining and Metallurgy have recently been announced: Consolidated Gold Fields of South Africa Limited Gold Medal to Mr. C. R. Julian for his paper on "Underground Mining at Rio Tinto, Spain"; Consolidated Gold Fields of South Africa Limited Premium of forty guineas conjointly to Mr. J. Spalding and Mr. T. W. Parker for their paper on "Air-Conditioning Plant at the Ooregum Mine-Kolar Gold Field"; William Frecheville Students' Prize of ten guineas conjointly to Mr. J. E. Denyer and Mr. K. C. G. Heath for their paper on "Mining and Milling Tin-Tungsten Ore at Mawchi Mine, Burma". The Council has also elected Mr. H. K. Picard to honorary membership, in recognition of his distinguished services to metallurgy.

MESSRS. CHARLES BAKER, of 244 High Holborn, London, W.C.1, are desirous of making an appeal to readers of NATURE to offer for sale certain apparatus which they are able to release for work of national importance. The whole of the British scientific industry is engaged on the production of apparatus for war purposes, the result being that the supply of instruments required for research, education and routine inspection work is severely limited. The demand for such instruments is constant, and increasing from every quarter, not only from official sources, but also from the industries engaged on work of the greatest importance. The following apparatus is of special interest: microscopes, optical equipment and accessories, telescopes, balances, spectrometers, refractometers, surveying apparatus, slide rules and drawing instruments.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Physiological Origins of Cellular Potassium

EQUATIONS describing potassium equilibria across cells have been considered in a previous communication[1], and more fully elsewhere[2], with experimental proof of the principles involved with respect to potassium accumulation. Such potassium equilibria are largely conditioned by the nature of the products formed in the cell, especially the phosphate esters, and by the characteristic permeabilities of the membrane. That there is some association of potassium with phosphate is evident if only from an inspection of ash analyses, but the real problem for this special cation accumulation has lain in the manner of its occurrence and physiological significance. With this latter, or functional value, as distinct from mechanism the present communication is concerned.

At the outset we may consider a freely distensile membrane permeable to univalent cations and anions (which latter with plasma external to the cell may be either uni- or divalent, since divalent anions are in negligible quantity).

The following equation then applies (neglecting activity considerations in an initial presentation):

$$\eta/V + \Sigma b_1 + \Sigma d_1 = c, \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where η/V is concentration of indiffusible substances in cell; Σb_1 is concentration of diffusible cations; Σd_1 is concentration of diffusible anions; c is total external concentration; V is volume of cell water, which may be taken as unity for the normal cell condition, so that:

$$\eta = c - (\Sigma b_1 + \Sigma d_1). \quad . \quad . \quad . \quad . \quad (1a)$$

Also,

$$\varepsilon = \Sigma b_1 - \Sigma d_1 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where ε is the excess of anion over cation equivalents for the indiffusible substances within the cell.

From equations (1*a*) and (2), and using the Donnan relation, we can write:

$$\eta = c - \sqrt{(\varepsilon^2 + 4\Sigma bd)}, \quad . \quad . \quad . \quad . \quad (3)$$

where Σb and Σd are the concentrations of the diffusible ions external to the membrane.

Considering frog plasma, and expressing concentrations as millimols per litre (and not including in '*c*' neutral molecules freely diffusible across the membrane), we have from equation (3):

$$\eta = 230 - \sqrt{\varepsilon^2 + 4 \times 111 \times 108},$$

or when ε is zero

$$\eta = 11.$$

With a *p*H value necessarily within 7·0 and 8·0 in such a cell, ε for the protein alone will be about 50 or more, and even if this is balanced in part by indiffusible base, this latter will only use up the small available concentration for η. The arrangement would therefore appear to be a very disadvantageous if not an impossible one for the cell, which under the conditions could accumulate no appreciable amount of phosphate esters (and these it may be noted will contribute about double or more their molal values to ε). The position is somewhat worse if the cell membrane be permeable also to divalent cations, and when permeable to cations only and not to anions, or vice versa, no free inorganic cation or anion could be accumulated during the formative period of the cell.

If, however, we consider the cation permeability limited a stage further to exclude sodium but not potassium (while anions up to the level of inorganic phosphate can also pass), then the condition greatly alters to the advantage of the cell. Equation (3) becomes:

$$\eta = 230 - \sqrt{\varepsilon^2 + 4 \times 2{\cdot}6 \times 108};$$

or, when ε is zero:

$$\eta = 197, \text{ instead of the previous } 11,$$

much the greater part of the total concentration being thus available for indiffusible material within the cells.

When the value of ε is 124, as it appears to be in the living muscle, then η is in turn as high as 102, and for the muscle immersed in the cold and sustaining various potassium equilibria, the two values are almost identical at approximately 104 each. It will be seen, therefore, that the arrangement is of the greatest advantage to the cell, securing the balance of protein anion charges as also the charges on the phosphate esters by inorganic cations derived from without, while at the same time securing a wide range of possible concentration for indiffusible molecules or ions.

Such considerations apply not only for plasma, but also for sea-water in contact with cells having distensile membranes. Even for algæ with membranes not freely distensible the selective permeability to potassium still offers the advantage of securing adequate conditions without large internal pressures. For the non-distensile cell membranes of the root or absorbing cells of land plants, we must seek a further explanation. The special permeability could here be regarded as the retention of a condition evolved in a primitive marine environment, but it would seem better to limit the consideration to real advantages. One of these would relate to the pore size, which is less than if sodium ions were allowed through and may help, therefore, in retaining valuable substances within the cell. A more important point is probably the following. The total concentration of potassium in the soil is more constant than sodium and appears to be better adsorbed and held on the surface of soil particles. If the absorption of salts is determined—as we may expect from thermodynamical considerations—by the product of the diffusible cation and anion concentrations, and if in turn the synthetic processes within are dependent on the concentrations—necessarily minute—of nitrate and phosphate ions, then a greater uniformity of growth and nutrition will be secured when the cation permeability is limited to the potassium level.

Effect of X-Rays on the Regeneration of Root Cuttings

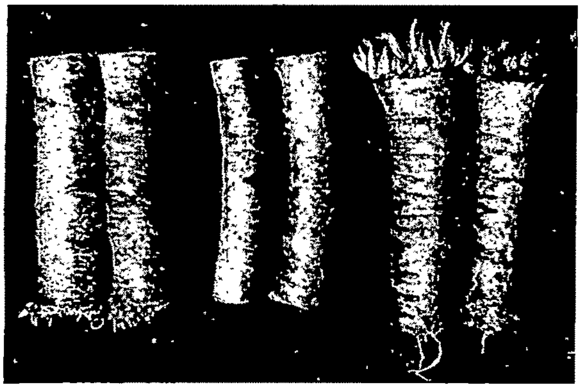
Root cuttings (thongs) of seakale (*Crambe maritima*) are known to exhibit marked polarity. In a former communication[1] a method was described of producing buds at the morphological base of a thong by periodic decapitation of both apex and base over a period of eight weeks. A working hypothesis, recently elaborated as a result of subsequent experiments[2], was also outlined regarding the correlation between auxin and meristematic activity. It was suggested that relatively low and high concentrations of auxin controlled the formation of bud and root initials respectively.

A recent experiment carried out here with the use of X-rays not only adds support to this hypothesis but has also resulted in the production of buds at the base of a thong within two weeks from treatment.

Skoog[3], irradiating *Avena* coleoptiles and solutions of heteroauxin with X-rays, claimed that the growth-substances involved were inactivated. Since the seakale root contains auxin[2], thongs were subjected to X-rays with the intention of reducing the total amount of growth-substance in the tissues and thus preventing, as a result of polar transport, the presence of a relatively high concentration at the base.

New thongs, 8 cm. long, cut transversely at each end were used. The parts of the thong treated with X-rays were as follows: (1) upper 3 cm. of the thong; (2) lower 3 cm.; (3) whole 8 cm. Each treatment was divided into three lots and irradiated with 1,000, 5,000 and 25,000 r-units respectively. A normal set of thongs was used as a control. Following treatment with X-rays the thongs were incubated in sand at a temperature of 20° C. and afterwards classified according to their appearance after eighteen days.

Control thongs produced buds at the apex and roots at the base (see accompanying figure, C). The dosage of 1,000 r-units had little effect on the regeneration of thongs in all treatments although root production was slightly decreased especially in (3). However, using concentrations of either 5,000 or 25,000 r-units, thongs receiving irradiation on the upper half produced buds at the base whilst their corresponding apices were inactivated (A); those irradiated on the lower half formed buds apically and remained inactive basally. Thongs given total irradiation remained inactive (B).



A B C

A, buds basally, apex inactivated. *B*, ends inactivated. *C*, normal thong.

From these results, it appears probable that there is a critical dosage which could be given to the middle regions of the thong for the purpose of partially destroying the auxin supply and thus eventually causing the formation of buds at both ends. Further experiments will be carried out to verify this point.

I am indebted to Prof. R. H. Stoughton for the supervision of this work and also to Metropolitan-Vickers Electrical Co., Ltd., who kindly consented to carry out the X-ray irradiation of the seakale thongs.

Ovarian Damage in Mature Baboons produced by Progesterone and Œstradiol Benzoate

It has been repeatedly shown[1] that the administration of progesterone in amounts of 15–20 mgm. to normal adult baboons in the first part of the cycle (eighth–tenth day) will cause the turgescent perineum to undergo deturgescence, and premature bleeding supervenes within 5–8 days of the last injection. Any quantity of progesterone more than 3 mgm. and less than 15 mgm. will only cause perineal deturgescence.

Examination of the ovaries of baboons treated in this fashion surprisingly reveals the development in one ovary of one or two follicular cysts which may be four times the size of a normal ovary.

Cystic ovaries therefore have been induced in primates by a hormone other than A.P. or A.P.L. substances.

The administration of a single injection of 0·5–5·0 mgm. œstradiol benzoate to baboons in the first part of the cycle will also cause perineal deturgescence which lasts 12–16 days instead of 5–8 days as after progesterone. The experimental cycle is prolonged by 18 days, that is, menstrual bleeding occurs on the fifty-sixth day instead of the usual thirty-eighth. Both ovaries of such œstrogen-treated baboons show degeneration of the stratum granulosum of all the follicles which contain follicular fluid.

If œstradiol benzoate is given daily to baboons from the eighth day of the cycle, then the perineum continues to rise and may be maintained in a state of turgescence for as long as the injections are continued. The ovaries display massive atresia of follicles and there remain only a few apparently unaffected fluid-containing follicles.

If both œstradiol benzoate (1 mgm.) and progesterone (5 mgm.) are simultaneously administered on the eighth day of the cycle the perineum undergoes deturgescence. A large cyst is produced in one ovary and massive atresia of follicles in both.

The second or third cycle succeeding those which were disturbed experimentally may not deviate very much from the normal.

Œstradiol benzoate, progesterone or a combination of both hormones given to normal adult baboons in the first part of the cycle causes widespread ovarian damage, albeit, perhaps, of a temporary nature.

Time as an Imaginary Fourth Dimension of Space is Incoherent

IT may be profitable in relation to current paradox to inquire very briefly into the relation of time to space. Consider two adjacent localities, one around a centre P and the other around a centre Q. The familiar conical diagram asserts that for any sublocality that is within a certain cone centring on P the relative time is real, while outside that cone it is pure imaginary; and likewise for a cone centring on Q. These cones intersect: and there are regions R, inside one of them and outside the other, for which time is real in relation to P and imaginary in relation to Q, or, in current language, the region around R is time-like in relation to P but space-like in relation to Q. This is something far more complex than the properties of a simple continuum such as a practicable space.

The paradox here suggested may be traced back into the ultimate foundations. The doctrine of the Principle of Special Relativity has been condensed into the slogan that "Henceforth Time and Space are no more". The mathematical Theory of General Relativity has been built up around the postulate (memoir of 1916, English edition, § 3, p. 117) that "the general laws of nature are to be expressed by equations which hold good for all systems of coordinates, that is, are covariant with respect to any substitutions whatever (generally covariant)".

The present critique has been stimulated by the observational result that the vast universe of the spiral nebulæ may be in a state of uniform expansion[1], for this suggests the question to determine the formulæ which express that expansion, as the formulæ of the Lorentz transformation express a uniform motion of translation. To my surprise, there appears to be no such set of formulæ. Thus permanent uniform expansion is impossible, so that in the course of time this expanding universe will cease to be uniform; which, by the way, is an alternative mode of accounting for the actual defect from uniformity that has been recently announced. But much more than this, the restriction of permanent uniformity to uniform translatory motion of the frame of reference carries us 'back to Newton', as the phrase goes, and may be even held to provide the explanation of this restricted indeterminacy of his frame of reference in space and time.

All such restrictions appear to be in flat contradiction to the postulate quoted above of General Relativity. The explanation is perhaps not far to seek: for if there is no longer time or space, there cannot any longer be velocity as the mode of expressing motion. But the formulæ here sought, and relations expressed in terms of them, would involve the velocity of one frame of reference relative to the other. Therefore such relations could not express laws of Nature: and these laws would have to be reformulated in terms of variables which probably have no intuitive relation to knowledge based on observation as given by our actual senses. The purely mathematical constructs of Ricci, now named tensors, are perhaps intended to be the foundation of a (very limited) formal universe expressed by variables of this kind. Meantime, the present astronomy, the queen of the mathematical sciences, would remain provisionally.

The reply to this critique might be to ask what is the alternative. For the tensor theory has led to a few results, of extremely special type, some of which have been in part confirmed. An answer appears to be that the tensor theory is far too wide a frame for the actual universe of Nature, which involves six freedoms, three for position and three for motion, whereas the tensor framework works with ten variables (potentials), so that the universe of Nature would have room, so to say, to rattle about in it, while as regards some of the specially simple test questions that are practicable the four extra variables may not come into play.

There can be a further claim, that a systematic doctrine of a duly restricted progress of dynamical Action of the system in time, can profitably absorb the valuable elements of these theories which are a natural general foundation for physics, and of the wave-mechanical as well, by going back a century to utilize W. R. Hamilton's procedures.

Malaria in War

WITH reference to the interesting paper on malaria by Dr. V. B. Wigglesworth in NATURE of April 12, p. 436, I offer a short account of the methods used at Taranto during the War of 1914–18.

In 1917 the lines of communication for Salonika, etc., were taken through France and Italy to Taranto. In that year the rest camp at Taranto was hurriedly organized and with some 60,000 men passing through there were some 600 cases of malaria. In the winter of 1917–18 it was decided to deal with mosquitoes there; and to deal with all swamps, etc., within 2,000 yards of the camp. Colonel Robertson, R.A.M.C., was our expert, with great experience in India, of such work.

As Director of Works, Italy, I wired to the Director of Works, France, "Send me your best Land Drainage expert for Taranto." He replied, "You have got him—try Kenworthy" (who was then in charge of R.E. Stores at the base). Major Kenworthy in civil life was a land drainage consulting engineer.

Kenworthy with his experienced eye at once saw that excellent work had been done by the Italians; but that owing to a technical omission the ditches had been allowed to relapse. So he cleaned them of growths; and dug a smaller trench at the bottom of small section to deal with low-water flow and maintain sufficient velocity, while the old ditches dealt with floods. Some tile drainage was required also. Various farms had wells with buckets which were good breeding places. However, the farmers were pleased to have them sealed when Kenworthy gave them good pumps to replace the buckets. Hollow places in the olive trees were filled with mud. A few puddles after rain required attention. Robertson kept a small squad of men catching mosquitoes with butterfly nets. He plotted the catches on a large-scale plan, disregarding sporadic ones ; so that when groups of mosquitoes were shown, an examination would reveal some hollow tree missed or something else easily put right.

The cost was £4,000, whereas I had been expecting ten times that sum. About the same cost was incurred in fitting wire gauze to the huts, which in this case proved unnecessary. As a result in 1918, with some 120,000 men passing through, we had only five cases of malaria. Of these, three were men who went out of bounds (one was a man sent out of bounds on duty), and one was unexplained. I suppose that cases of malaria returning from Salonika were not counted.

The inference seems to be : take a good malariologist, a good land drainage engineer and give them a free hand.

Colchicine-induced Tetraploids obtained from Plants of Economic Value

FROM the work of Kostoff[1] and others we have learned that length and number of the chromosomes are decisive in determining the value of derived tetraploids. Long chromosomes diminish fertility much more than short ones do. The greater their number, the lesser their viability. In consequence one has to choose from plants possessing a reduced number of chromosomes of moderate length.

Furthermore the purpose for which the plants are grown must be taken into consideration. After doubling the chromosome number, tobacco plants will lose their subtle properties of quality almost immediately. Tetraploid fibre-plants, however, may greatly augment the yield. We should therefore consider, whether the important properties are of a quantitative or qualitative nature.

Another fact must be remembered, namely, that creating a tetraploid means producing a completely new biological system. Finally, the action of colchicine may bring forth structural and numerical changes, chromosome breakages, etc., providing a new basis for unbalanced chromosome complements, variability and sterility.

The above-mentioned points were studies on tetraploid *Nicotiana tabacum* L. (Vorstenlanden and Virginia tobacco) and tetraploid *Hibiscus cannabinus* L. (Java jute, Ambari hemp, Decan hemp, Bimlipatam jute).

Tetraploid tobacco was obtained as usual and without difficulty by seed treatment. First of all it was noticed that the tetraploid strains still could be recognized by constant characters, although the general properties had been greatly altered. All tetraploid tobacco plants were smaller than the original diploids. This is in accordance with the large number of comparatively long chromosomes ($2n = 48$) tobacco possesses.

As the enlarged cells contain more chloroplasts, which have not increased in volume, the leaves are darker green. We can assume the production of carbohydrates per unit of leaf surface to be stimulated. This is of interest in the case of Virginia tobacco, the sugar content of which plays an important part in estimations of quality.

The increased leaf thickness makes it possible to produce cigarette tobacco with more 'body', although too thick a leaf may involve difficulties during the process of 'flue curing'. The fine quality of cigar tobacco is completely spoiled by the coarseness of the tetraploid leaf. Moreover the latter is supported by a very irregularly developed framework of veins.

However, here we have to recognize a difference between the primary and the secondary colchicine effects[2]. In most cases the properties of tetraploid plants, grown from treated seeds, are unfavourable, although the Virginia leaf sometimes showed good structure and shape. Diploid tobacco already being a multiple tetraploid, we find a great variability among the offspring of the tetraploids. Most of the plants still closely resemble the mother plant, but some of them tend to improved leaf structure.

Tetraploid Virginia tobacco differed from tetraploid Vorstenlanden tobacco in two other points : the percentage of pollen sterility of the former was higher, while its root tips (so far as I could examine them) contained the diploid number of chromosomes. In root tips of cigar tobacco I always counted about 96 chromosomes.

Many aberrations of merely theoretical interest in the structure of flowers and leaves were found.

A new fact is the occurrence of a number of somatic gene mutations, some of which may obtain practical importance. Their progeny will be examined in order to test the quality.

Tetraploid plants from Java jute (a fibre-plant) were obtained with some difficulty by treating apical meristems with colchicine solution or with the emulsion prescribed by Warmke and Blakeslee[3].

Hibiscus cannabinus is more resistant to diseases as compared with *H. Sabdariffa* (Rosella). On Java the latter is cultivated because the yield is higher. Tetraploid Java jute may combine higher yield with greater resistance.

In this case the chromosomes are small and the cells only contain a moderate number of them ($2n = 36$). Therefore we do not expect very pronounced differences between the diploids and the tetraploids. The experimental results confirm the expectation.

Marked differences in rate of growth, which are characteristic of tobacco, are not observed. In this respect cultivation of the tetraploids meets with no difficulties. Furthermore diploid and tetraploid types closely resemble each other.

The tetraploids may be distinguished by the following characteristics. The plants are ramified to a lesser degree, the leaves show a strong tendency to remain undivided. The tetraploids also show stiff, dark green and thick leaves, broad petals, a strongly developed epicalyx, a high percentage of pollen sterility, stomata with larger diameter, big seeds. In cross-sections of root tips, 72 chromosomes could be counted.

RESEARCH ITEMS

Genetical Calculations

I. M. H. ETHERINGTON (*Proc. Roy. Soc. Edin.*, B, **61**, 24–42 ; 1941) shows that a linear algebra may be constructed which corresponds to genetical phenomena relating to gametes and zygotes. By using this algebra on the usual genetical symbols of a cross it is possible to alleviate laborious calculations of the results of types of mating and population studies. The author shows that the derived algebra differs from the usual in that $P \times (Q \times R)$ does not equal $(P \times Q) \times R$.

Triploid Newts

R. B. GRIFFITHS (*Genetics*, **26**, 69–88 ; 1941) has produced triploid and haploid newts by refrigerating eggs at close to 0° C. for about twenty hours after fertilization. Out of 100 eggs raised to swimming larvæ, 80 were triploid, 10 were diploid, and 10 were haploid. Since no triploid larvæ arose from refrigeration delayed half-an-hour after fertilization, it is suggested that the second maturation division is inhibited by refrigeration and the second polar body is retained in the egg. Triploid larvæ have larger nuclei and cells in the epidermis, erythrocytes and other parts, but show no gigantism ; the number of cells is fewer than in the diploid. Seventy-five of the triploid larvæ showed normal development and fifteen of these were examined during metamorphosis and found to be female. The haploid larvæ were dwarfed and more or less œdematous.

Genetics of Aquilegia

B. SCHAFER (*J. Gen.*, **41**, 339–348 ; 1941) has summarized the results of her genetical experiments on *Aquilegia vulgaris*. The allelomorphic genes *Bb* for blue-pink flower colour, *Cc* for tall-compact habit, *Ll* for blue-lilac flowers, and a multiple allelomorph series *A*, *aw*, *a* for fully coloured, white-faced, and completely white flowers were studied. *c*, *l* and *a* form a linkage group with cross-over values of 0·0428, 0·136 for *C*—*l* and *l*—*a* and 0·1523 for *c*—*a*. In one family, complete linkage between double flowers and tall habit was found while in another two families independence was observed. The aberrant results in the first family might be due to an inversion of a chromosome. The interspecific relations of species of Aquilegia are discussed.

Germination of Orchid Seeds under Sterile Conditions

THE possibility of growing orchid seedlings under sterile conditions, once regarded as almost impracticable, has of recent years, in part through the work of Knudson, been carried out so successfully that, in effect, orchid hybridization and subsequent seedling production has become a standardized and very profitable technique, and the work of a few growers is probably still contributing appreciably to British export efforts. But it does not follow that Knudson's claims are as firmly established that, in Nature, the usual fungus symbiont is simply necessary because its digestive activities supply soluble sugars from organic substrates—within or without the seeds. D. G. Downie has recently shown in her careful studies of the germination of the relatively rare British orchid *Goodyera repens* Br. (*Trans. and Proc. Bot. Soc. Edin.*, **33** (1), 36–51 ; 1940) that the seeds germinate readily under aseptic conditions in the presence of sugar, but not in mineral nutrient solutions over a wide range of *p*H. If the endophytic fungus is present, then no outside source of carbohydrate is necessary to start germination. By a wide range of experiments, she brings much support for Bernhard's classic view of mycorrhizal symbiosis. These views have of recent years been strongly supported by Rayner in Great Britain against the argument of Knudson that sugar and not the symbiont is the necessary factor in germination.

South Atlantic Earthquake of August 28, 1933

THIS is the subject of a most valuable paper by James T. Wilson ("The Love Waves of the South Atlantic Earthquake of 28th August, 1933" ; *Bull. Seis. Soc. Amer.*, **30**, No. 3 ; July 1940). The epicentre of the earthquake, located by Geiger's method, appeared to be lat. 58° 56′ S., long. 24° 54′ W., and the initial time 22h. 19m. 38s. U.T. using Gutenberg and Richter's tables. From a stereographic projection of the initial motion at several stations near the epicentre, it was determined that the earth movement which caused the earthquake was probably a fault striking between N. 33° W. and N. 1° E. and dipping between 63° and 76° to the east, the movement at the time of the earthquake being such that the west side moved north with respect to the east. In studying the seismograms, special reference was paid to the *G* wave portion, which was integrated by means of the mechanical integraph of Prof. L. D. Leet. From the earth motion diagrams so obtained it appears that the waves were Love waves, and that where the paths had been under the ocean almost all the energy was in the first period of the group. Furthermore, to a reasonable approximation, it was considered that on mixed paths all the dispersion took place on the continental part of the path. The amount of dispersion along the oceanic paths was much less than along the mixed paths, and from the data the author points out that there is no reason to assign different crustal structures to the different ocean basins. For example, the data from Ivigtut on an Atlantic path is practically the same as that from Honolulu on a Pacific path, and very similar to that from other stations which are on paths through the Indian Ocean basin. The structure of all the oceans appears to be characterized by having material in which shear waves have a high velocity much nearer the surface than is observed in the continental regions. The thickness of the crustal structure in continental regions, according to the author, appears to be about 30–40 km.

The Melting Range of Fats

A PHOTO-ELECTRIC method for the determination of melting points of fats by which the present lack of consistency between the results of different observers using the capillary tube method may be avoided was described by K. A. Williams at a meeting of the Society of Public Analysts and other Analytical Chemists on February 5. The fact that melting starts at a temperature below the visual melting point is confirmed by a modification of the dilatometric method which leads to reproducible and definite results for the true incipient and complete melting points. The possible use of figures for change in volume on melting and for the rate of change of density with temperature during melting is suggested as a means of characterizing fats.

Thermodynamic Properties of Propane

RECENT developments in the utilization of propane have revealed the need for more complete information upon its thermodynamic properties. The available physical and thermal data have been summarized and correlated, and some new experimental determinations of pressure-volume-temperature relationships for the liquid at low temperatures have been carried out by J. H. Burgoyne (*Proc. Roy. Soc.*, A, **176**, 280–294; 1940) at the Imperial College, London. On the basis of the information thus obtained, the entropy and enthalopy of propane have been calculated for conditions of temperature between −80° and 200° C., and at pressures of from 0·1 to 200 atmos., and are presented in a folding chart with the paper.

Covalent Radii

IN the system of covalent radii developed by Pauling and Huggins the length of a covalent bond is equated to $r_A + r_B$ where r_A and r_B are the covalent radii. For example, in the ethane, chlorine and carbon tetrachloride molecules the bond-lengths are given (in A. units) $r_{\text{C-C}} = 1{\cdot}54 = 0{\cdot}77 + 0{\cdot}77$, $r_{\text{Cl-Cl}} = 1{\cdot}98 = 0{\cdot}99 + 0{\cdot}99$, $r_{\text{C-Cl}} = 1{\cdot}76 = 0{\cdot}77 + 0{\cdot}99$. If the bonds are not single covalent bonds other sets of radii are used. Recent measurements with fluorine, hydrogen peroxide and hydrazine indicate an upward revision of the radii for fluorine, oxygen and nitrogen, and with these revised values many bond-lengths which obeyed the additivity rule with the old values are now significantly less than the sums, while for electronegative pairs (F–O, Cl–O, etc.) the bond-lengths are generally less than or equal to the radius sums, although they are greater than the lengths derived from the old radii. V. Schomaker and D. P. Stevenson (*J. Amer. Chem. Soc.*, **63**, 37; 1941) now show that new values of the normal covalent single-bond radii of hydrogen, nitrogen, oxygen and fluorine can be derived which are consistent with the bond-lengths in the hydrogen, hydrazine, hydrogen peroxide and fluorine molecules. The additivity rule for bond-lengths is shown to be no longer generally valid but it can be used with a correction for the ionic character of the bond. The latter involves the so-called electronegativity on the Pauling scale. For many carbon bonds the additivity rule gives better results than the new equation. It is concluded that bond-lengths are affected significantly by even quite small amounts of ionic character.

Asymmetry of Cosmic Radiation at High Latitudes

TWO papers on the east–west asymmetry of the cosmic radiation at high latitudes appear in the January number of the *Physical Review*. F. G. P. Seidl (**59**, 7; 1941) has measured the sea-level east–west asymmetry of unabsorbed cosmic radiation and of that radiation penetrating two thicknesses of lead, 20° from the vertical, at geomagnetic latitude 54° N., well above the 'knee' of the latitude effect. A theoretical treatment is given by T. H. Johnson (**59**, 11; 1941). The slight east–west asymmetry of the cosmic radiation is interpreted to be the result of the deflection by the earth's magnetic field of the mesotron component while the rays are losing energy by ionization in the atmosphere. Since this component contains about 20 per cent more positive than negative rays, these deflections result in an asymmetry. Orbits of rays, including those in the range of energy where rest-mass cannot be neglected, have been investigated, and the deflections without energy loss, namely, those of the primary rays described by the theory of Lemaître and Vallarta, result in a symmetrical distribution for the energy ranges concerned. The asymmetry is traced to the *difference* between the actual deflection and that of a ray which loses no energy. The 'difference' deflection δ shifts the angular distribution so that rays which, in the absence of a field, would have produced an intensity proportional to $\cos^2\zeta$ at zenith angle ζ actually produce this intensity at an angle $\zeta + \delta$. Asymmetries calculated in this way agree with the observed values, and give the correct variation of asymmetry with zenith angle and elevation.

Nature of Solar Hydrogen Vortices

THE cause of the vortex-like markings surrounding sunspots on spectroheliograms taken in the centre of the $H\alpha$ line has long been a vexed question. Two theories have been advanced to account for the patterns observed: first, that they are associated with magnetic fields produced by charged particles whirling below the solar surface; second, that they are true vortices in the hydrodynamical sense. In the January issue of the *Astrophys. J.* (**93**, 24; 1941), R. S. Richardson examines all Mount Wilson spectroheliograms taken over the period 1908–1939 in an attempt to decide which explanation is the more likely. If the particles partaking in the low-level whirl of the first hypothesis are always of the same sign, all spots with the same polarity should have the same direction of whirl; and when the general reversal of polarity occurs at sunspot minimum there should also be a reversal of direction in the vortices. In fact, however, the tendency is for clockwise whirls to appear in the southern hemisphere, counterclockwise ones in the northern hemisphere, regardless of the polarity of the underlying spot. This result, derived as it is from 141 vortices distributed over three sunspot cycles, seems likely to establish the supremacy of the hydrodynamic theory, namely, that the direction of a hydrogen vortex is determined primarily by the solar rotation, and is not connected with the polarity of the associated sunspot.

Photo-Electric Observations of 12 Lacertæ

H. E. GREEN has published (*Mon. Not. Roy. Astro. Soc.*, **101**, 1) results of observations of this star from August 30 to October 29, 1940, with the Sheepshanks Telescope, Cambridge Observatory. No detailed discussion is given as the observations are intended to be combined later with those of Prof. Fath, who carried out similar work over the same period at Lick Observatory. The comparison star was 10 Lacertæ and on some nights control observations were made on 9 Lacertæ; the fourth column of the table gives the differences (9 Lac.–10 Lac.) which should be constant. It is pointed out, however, that these control observations are likely to be much less accurate than those of the variable itself, owing to the greater distance between the stars requiring about ten times the atmospheric extinction corrections.

RADIOACTIVE INDICATORS, ENTERIC COATINGS AND INTESTINAL ABSORPTION

PROF. K. LARK-HOROVITZ AND DR. HERTA R. LENG*
PURDUE UNIVERSITY, LAFAYETTE, INDIANA

CERTAIN medicaments cannot be administered orally without either irritating the stomach tissues or becoming destroyed by the gastric juice. To avoid these effects they are given in pills with enteric coatings. Such coatings are supposed to pass the stomach undissolved and to dissolve only in the small intestines.

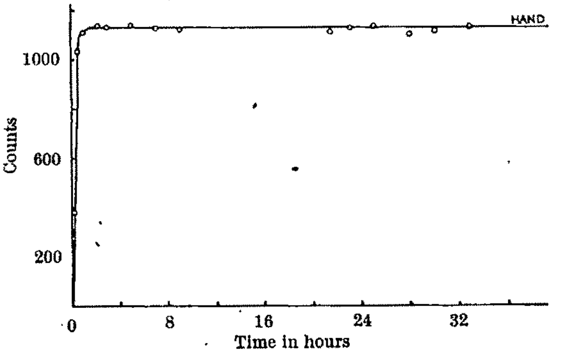

Fig. 1.

UP-TAKE OF RADIOACTIVE SODIUM AS MEASURED BY THE ACTIVITY OF THE HAND. 0·3 GM. Na^*Cl : SODIUM ABSORBED FROM STOMACH.

Since the introduction of enteric coatings by Unna in 1884, various methods have been tried to test their efficacy. In recent years X-ray radiology has been used[1]. The methods used so far do not detect cracks in the coating, which may lead to a leakage and consequently to destruction of the contents by the gastric juice.

Radioactive materials as fillings are obviously admirably suited for such tests. Any crack in the coating is detected at once by the appearance of the radioactive material in the blood-stream as measured by the activity in the hand, and the capsule itself can be easily followed on its way through the digestive tract until it is dissolved. The experimental arrangement, therefore, is the following: Ordinary gelatin capsules are filled with about 0·3 gm. of radioactive sodium chloride obtained by bombardment with 8·5 Mev. deuterons for about 2–6 μ amp.h. The initial activity of the sample is of the order of 500–700 μC. The capsule is coated with a mixture of shellac, castor-oil and alcohol following a formula of Prof. C. O. Lee of the School of Pharmacy, Purdue University. The capsule is administered orally and is followed through the digestive tract with the aid of a movable bell-type counter. Simultaneously, the activity of one hand of the patient is measured to determine the movement when the active material has reached the blood-stream.

Fig. 1 shows the activity as a function of time when the salt has been administered orally without the coating. The first sign of activity in the hand is detected a few minutes after intake; it then increases steadily to reach a constant value in about 3 hours[2].

Fig. 2A shows the location of a coated pill in the digestive tract, throughout the experiment. In this particular case, it is located for about one hour in one position in the stomach; then it moves towards the pylorus and can be located again in the small intestines. After 2½ hr. the movable counter indicates that the pill dissolves and the activity is spread over a large area. Now the activity appears also in the hand, which was, up to this time, entirely inactive.

TABLE 1.

	Total No. of Exp.	Dissolved in Intestines	Dissolved in Stomach	Unknown	Not dissolved
Handcoated pills	21	14 (66 per cent)	2 (10 per cent)	3 (14 (per cent)	2 (10 per cent)
Commercial coatings	10	5 (50 per cent)	4 (40 per cent)	1 (10 per cent)	

Fig. 2B shows the activity in the hand throughout the experiment. The first activity is observed after about 2½ hours, when the pill starts to dissolve; it reaches a maximum after about 8 hours (5½ hours

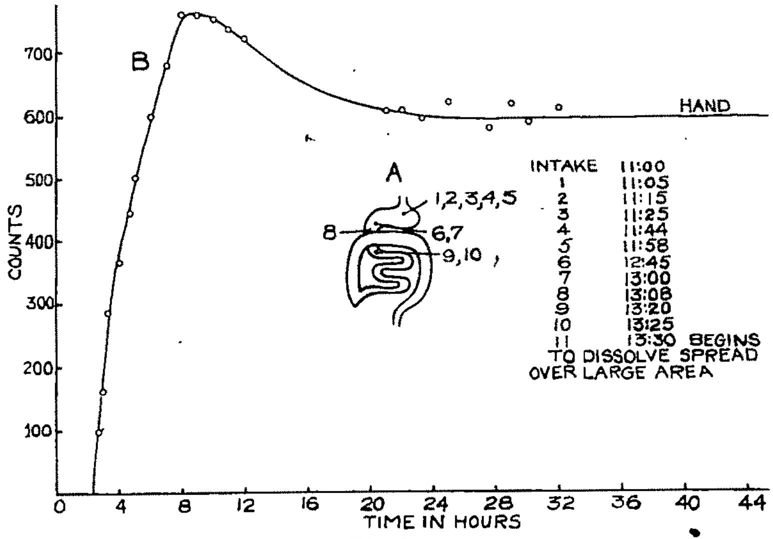

Fig. 2.

UP-TAKE OF RADIOACTIVE SODIUM FROM THE SMALL INTESTINES AS INDICATED BY THE ACTIVITY OF THE HAND. THE POINTS IN THE SCHEMATIC DRAWING *A* ARE, OF COURSE, ONLY APPROXIMATELY LOCATED. 0·3 GM. Na^*Cl IN COATED PILL, DISSOLVED IN SMALL INTESTINES AFTER 2 HR. 20 MIN.

---

* Aurelia Henry Reinhardt International Fellow of the American Association of University Women.

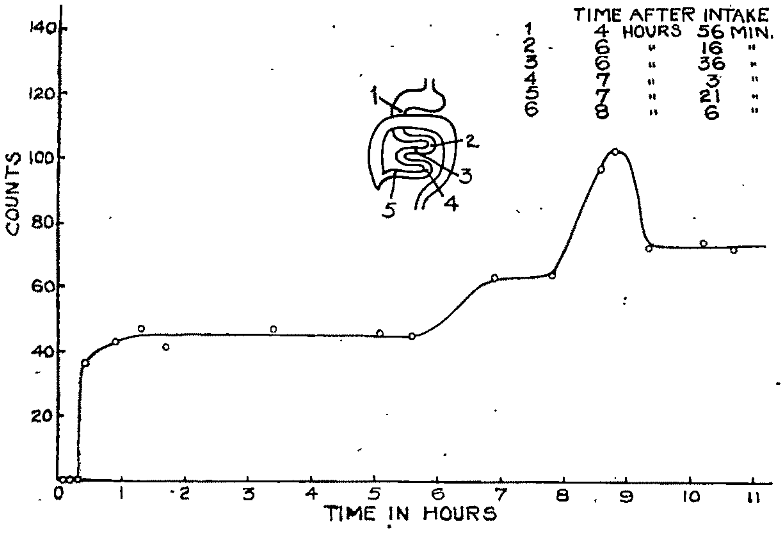

Fig: 3.

Up-take of radioactive sodium from the small intestines; the enteric coating had a leak. 0·3 gm. Na*Cl in enteric coating dissolved in small intestine after 8 hr.

after it started to dissolve) and then decreases to equilibrium value.

Fig. 3 was obtained with a pill which apparently was leaking, for an activity in the hand can be detected half an hour after intake. The pill itself could be followed for about eight hours, when it finally dissolved in the intestines. At this time the activity in the hand is raised, reaches a maximum in about one hour and falls again to a level higher than the first one, since now the total activity is distributed throughout the body.

Besides the handcoated pills, commercial coatings have been tested. In this case some 100 or 1,000 pills are coated at the same time, and the few active samples can be easily segregated with the aid of a counter.

The results in Table 1 indicate that the majority of the handmade pills dissolve in the small intestines.

In connexion with other experiments on the distribution of the sodium, potassium and chlorine ions in the body, we want to direct attention to the fact that the curve for the time-rate of absorption from the stomach is entirely different from the absorption-curve from the small intestines. In the first case the absorption reaches a level which remains constant for hours and decreases only after a large amount of the salt has been excreted. The absorption from the intestines raises the salt level temporarily and equilibrium is reached through back-diffusion, indicating that a local surplus produced by a sudden release of salt causes a real absorption through the wall of the intestines which is adjusted later by back diffusion and ionic exchange.

A detailed description of these experiments will be given elsewhere.

WORK OF THE BRITISH EMPIRE CANCER CAMPAIGN

By Dr. E. Boyland

The Chester Beatty Research Institute, The Royal Cancer Hospital (Free), London

The seventeenth annual report of the British Empire Cancer Campaign contains 280 pages as compared with 368 pages of the previous report. The total sum expended in grants in aid of research amounted to more than £40,000, as compared with £53,000 for the previous year.

Interesting advances into the possible origin of cancer have been made by examining human organs for possible carcinogenic agents. Some years ago, the Russian investigator Schabad prepared carcinogenic material from the liver of a woman dying of cancer of the stomach. Dr. des Ligneris has investigated this problem in South Africa, where cancer of the liver is common among Bantus, but not among Europeans. Extracts of livers from normal Europeans were not carcinogenic, but extracts from the livers of both cancerous and non-cancerous Bantus produced cancer in mice. Dr. I. Hieger is working on the problem in London, and has induced tumours in mice by treatment with the unsaponifiable fractions of livers from European cancerous and Bantu non-cancerous subjects. Several tumours in mice were obtained by treatment with the extract of a liver from a case of lymphosarcoma.

Normal human liver and bile contain deoxycholic acid and, as was reported in these columns (Cook, Kennaway and Kennaway, Nature, 145, 627; 1940), this acid is carcinogenic to mice when injected subcutaneously but not when painted on the skin. The carcinogenic material isolated from human livers is not likely to owe its activity to deoxycholic acid, as it is the unsaponifiable fraction which contains the active material.

Carcinogenic hydrocarbons in very low concentration are able to photosensitize Paramecia. Using this as a means of detection, Dr. J. C. Mottram has been able to show that when 3 : 4-benzpyrene is applied to mice, it accumulates in the liver and lungs. This is of interest, as it helps to explain the fact that some carcinogenic compounds induce tumours in these organs in certain strains of mice. The addition of benzpyrene to a culture of Paramecium kept in the dark increases the rate of growth, and after prolonged cultivation in the presence of the hydrocarbon many abnormal forms are produced (see also NATURE, 145, 184; 1940).

The relationship between carcinogenic action and inhibition of growth with change in chemical structure has been carefully studied and many new compounds have been synthesized. Most carcinogenic compounds inhibit growth, but 9:10-dimethylanthracene, which is a weak carcinogenic agent (and incidentally the simplest known carcinogenic hydrocarbon), does not inhibit growth. Dr. A. Haddow has tested many compounds for growth-inhibitory power, and has found that 1:2′-azonaphthalene inhibits tumour growth without being carcinogenic.

Definite inhibition of tumour growth with three types of compounds has been obtained by Dr. E. Boyland. Of the first group, of aldehydes and their possible metabolism products, citral and malonic acid were the most satisfactory; of the natural bases representing the second group, aminoethylalcohol and cadaverine gave definite results; while of the third group of aromatic diamines, 4:4′-diaminodiphenylether is the most promising. It would be of interest and value to know if some of these substances had any effect on cancer in human beings.

Dr. T. Lumsden, at the London Hospital, has tested the effect of adding normal tissue fragments on the growth of a mouse carcinoma in tissue culture. While pituitary tissue increased the rate of growth, liver fragments inhibited the growth. This latter result is in agreement with the results recently published by Brues, Subbarow and Aub in the United States, who found that the inhibitory effect of liver was in part due to aminoethylalcohol.

Prof. E. C. Dodds has continued his investigations into synthetic œstrogens, and with Dr. S. W. Stroud has studied the metabolism of these compounds in rabbits. Synthetic œstrogens appear to be more stable in the body than the naturally occurring œstrone. It was found that the œstrogenic hydrocarbon stilbene is converted into 4:4′-dihydroxy stilbene, which is much more active œstrogenically than stilbene. Several other related aromatic compounds are also converted into œstrogenic phenols in the body by an analogous change.

Dr. K. J. Bonser and Dr. J. M. Robson have examined the response of male mice of three inbred strains to synthetic œstrogens. In the *R* III strain, 60 per cent of the male mice developed mammary cancer while in two other strains (*C.B.A.* and Strong *A*) no such tumours appeared. In the Strong *A* strain the treatment caused hyperplasia of interstitial cells in the testis and the development of nodules, some of which had the histological characteristics of malignant growths. Dr. P. A. Gorer describes the post-mortem findings in three pure lines of mice. In the *C.B.A.* strain, cancer is found more frequently in males than females, owing to the high incidence of liver tumours in male mice of this line. In the Strong *A* strain, the incidence of mammary tumours is high in breeding females, particularly in animals which have frequent pregnancies but which fail to nurse their young. Mice of the *C* 57 black line are resistant to mammary cancer, but frequently develop lesions in the lymph glands, and leukoses. These differences in the types of cancer which occur in strains are possibly analogous to the differences in the occurrence of cancer in different human races.

Viruses which transmit tumours in fowls continue to be investigated in many laboratories. Dr. P. R. Peacock has compared the properties of filterable and non-filterable tumours. Tumours which can be transmitted from one animal to another by cell-free filtrates are much more resistant to the action of X-rays than tumours which cannot be transmitted in this way. Filterable tumours also remain infective after thorough mechanical disintegration which renders non-filterable tumours non-infective. These results suggest that it is unlikely that the non-filterable tumours contain a virus.

Methods for the purification of the Rous sarcoma virus have been developed by Prof. J. McIntosh at the Middlesex Hospital. By means of a modified Sharples centrifuge, considerable concentration of the virus particles was obtained. Dr. A. Pollard has analysed particles isolated in this way from the Rous sarcoma and other tumours, and also similar preparations of vaccinia virus and bacteriophage. The isolated particles from vaccinia, from the Rous sarcoma and from two non-filterable tumours are all similar in lipoid, protein and phosphorus content. Such tumour concentrates act as antigens when injected into rabbits, but in this reaction it is so far impossible to separate fowl and virus components. In other experiments it was impossible to immunize fowls against fowl tumours.

Dr. L. Hoyle, at Leeds, has examined a number of mouse tumours and extracted a lipoid antigen which does not appear to be present in normal mouse tissues. The same antigen appears to occur in several strains of tumours, but it is not present in all mouse tumours.

In the University of Sheffield Field Laboratory it has been shown that the immunization of rats to a transplantable dibenzanthracene rat sarcoma did not influence the induction of tumours by 1:2:5:6-dibenzanthracene. From this and other experiments it is concluded that no immunity to cancer can be expected using techniques based on the principles of bacterial immunity.

Dr. F. Dickens and Dr. H. Weil Malherbe have found that the metabolism of intestinal mucosa resembles that of tumour tissue. Reference is made to a discussion in NATURE (145, 512, 778; 1940) on the carbohydrate metabolism of tumours. It is now generally agreed that anærobic glycolysis and low respiratory quotient are not specific for cancer tissue.

Dr. C. E. Dukes has made a careful analysis of 1,000 cases of cancer of the rectum, a form of cancer known to be much more common in men than women. Lymphatic metastases from rectal carcinomata occur more frequently in men than in women, and these, along with the most malignant tumours, occur more often in young than elderly patients. On the other hand, the mean age of occurrence was earlier in women than in men.

The Clinical Cancer Research Committee has tabulated data from 7,872 case sheets which were received for the year 1938. Registration of new cases was suspended at the outbreak of war, but the data already available are being examined. It is very unfortunate that on some of the points there is a high percentage of "Not Stated" returns, which makes it impossible to draw definite conclusions from the figures. The suspension of registration of new cases should give opportunity to consider the results so far obtained and possibly to improve the methods of registration that will be used when the War comes to an end.

Although research in certain branches has been much reduced as a result of the War, when one considers the present situation it is gratifying to see that so much progress has been made during the year.

THE ROTHAMSTED FIELD EXPERIMENTS ON THE GROWTH OF WHEAT

By Dr. R. D. Preston
University of Leeds

It is perhaps fortunate that the approaching centenary of the Broadbalk experiment at Rothamsted has stimulated the publication of a detailed report on wheat studies carried out there, at a time when interest is growing rapidly in the question of the relative merits of farmyard and artificial manures. The Broadbalk experiment in particular has continued over a period sufficiently long to detect any progressive deterioration in the crop, resulting from the continuous use of artificial fertilizers. The present report[1] is of particular interest, since it includes not only the continuous wheat experiments themselves, but also a comparison with a variety of rotation experiments and with ordinary farming methods at a variety of stations.

The Broadbalk wheatfield was last year harvested for the ninety-seventh time in succession, and this is the third discussion which has appeared during that time. On the first occasion (1893) the first fifty years were reviewed by Lawes, the founder of Rothamsted, and his collaborator Gilbert, and on the second by A. D. Hall in 1905. Since 1919, the scope of the experiment has been widened considerably, and in particular the application of statistical methods not previously available has enabled much more information to be extracted from the existing data.

The Broadbalk field slopes downward from east to west, and is divided into strips running down the slope, each of which annually receives the same manurial treatment, different from that in other strips. There is no obvious important trend in fertility across the field; the soil is, in fact, everywhere rather poorly adapted to wheat cultivation, as evidenced by the relatively low yield (maximum 55 bushels per acre as against 60 bushels often yielded on farms and one observed yield of 96 bushels). Originally set up to disprove Liebig's theory that plants receive all their nitrogen from the air, many valuable data have been accumulated on the relative effectiveness of farmyard manure and a range of artificial fertilizers. It was early demonstrated that addition of nitrogen to the soil markedly increases the yield of grain and straw (for example, 44 lb. of nitrogen as ammonium sulphate gives an increase of 1 bushel of grain) but that minerals are also necessary. For grain production, sodium nitrate is considerably more effective than ammonium sulphate in a single dressing (43 lb. per acre) but not so much with a double dressing. For straw production sodium nitrate is always decidedly the more effective, and for both straw and grain spring application is preferable to autumn (due probably to less leaching from the soil). Levels of supply well above those in ordinary practice give greater yields. Perhaps the most important point in this connexion is that farmyard manure has only 44 per cent of the efficiency of sodium nitrate, and only 50 per cent of that of ammonium sulphate, when the artificial manures are added with complete minerals. Potassic fertilizers increase the yield both of straw and grain, an effect which is diminished by phosphate deficiency. This higher efficiency of artificial fertilizers does not appear to be offset by any progressive deterioration in the crop. During the period 1852–1918 the annual diminution in yield (eliminating random variations) was certainly lowest with farmyard manure (0·1 per cent of mean yield), but this was closely followed by the plot with complete artificials (0·26 per cent). The highest rate of deterioration was found in the plot receiving nitrogen and PO_4 without potassium, where it amounts to 1 per cent. It is interesting that on the unmanured plot, though yields fell from 20 bushels per acre to 10 in twenty years, they have not fallen lower except when weeds have become prevalent; in fact, during recent years they have risen.

This annual deterioration is attributed largely to changes in soil composition. All the plots with the exception of the farmyard manured have lost carbon and nitrogen compounds, but though the soil in the farmyard manured plots is different from that in others as regards physical properties there is no evidence that this soil is better suited to the wheat plant. There is certainly no suggestion, as the years go by, of progressive injury by rusts or by insect pests, though 'eye spot lodging' is somewhat more common than on crops grown in rotation.

Apart from this slight steady deterioration, the so-called 'annual variations' related to weather conditions, chance variations in cultivation, etc., have also been studied in detail. The main causes of such variations in yield are almost solely connected with weather factors; contrary to general belief time of sowing has no observable effect. The defect of the Rothamsted climate for wheat is that rainfall is much too high. In general it may be said that injury due to rain is least in October and greatest in or about January, when each additional inch of rain reduces the crop by one or two bushels per acre. This effect of winter rainfall is to be attributed partly to a leaching out of nitrogen (and is therefore least marked with farmyard manure), partly to excessive growth of weeds and, at Broadbalk, partly to the already heavy nature of the soil. The rainfall effect accounts for about ¼–⅓ of the total annual variation on most of the plots, though on the farmyard manured plots the effect covers about 40 per cent of the total and is the most important single factor concerned.

The chief practical difficulty in continuous wheat cultivation is the fight against weeds. The time between harvesting one crop and sowing the next is short and is usually not suited to the effective killing of weeds, and control is complicated by delayed germination of some weed seeds (2–9 years or more). The relation between weed infestation and wheat yield is not simple, but it is proved that wheat is ill fitted to stand up to the competition of weeds. Introduction of a fallow in order to eradicate weeds proved a success. The yield, which had been deteriorating, jumped immediately to the original level; an effect which is perhaps all the more striking as it lasted only one year. The main points about fallowing appear to be (1) that it enables control of weeds to be made and allows the formation of a better seed bed and soil conditions; (2) it allows an accumulation of nitrogen which may be very considerable (rising in plots with minerals only to the level of one with minerals plus 86 lb. N as ammonium sulphate); (3) it emphasizes the need for potash. Although the effect of a single fallow is so marked, a continuous wheat-fallow rotation commenced in 1856 (Hoos field) showed that the effect does not continue and a prolongation of the fallow to three years (Hoos field, 1932) or four years (Broadbalk, 1930) does not materially increase the yield. As regards the success of the old three-field system, it must be remembered that medieval fallows were never clean fallows; the land was left to natural vegetation and was grazed.

In 1930 an experiment on modern lines was begun at Rothamsted and at Woburn involving a six-course rotation of both crops and treatment. The wheat follows clover, and the yields without added manure are so good that added nitrogenous fertilizers have no effect at either station. Additional potash slightly increases the yield (Rothamsted) or, like phosphates, has no effect. In normal rotation conditions at Rothamsted (the Norfolk rotation—swedes (manured), barley, clover, wheat) begun in 1848 the addition of manure to the swedes had no effect on the wheat for the first twenty years, though afterwards the yields on unmanured land deteriorated more than on the manured. When clover failed it was replaced by beans, and both crops were found better than fallow except on unmanured land. The yields on all plots were similar, and resembled the Broadbalk continuous wheat yields with farmyard manures. In a mangold, barley, beans, wheat rotation (Saxmundham, commenced in 1899), however, the increase in yield with nitrogenous manure is almost the same as on Broadbalk, and here again the effectiveness of farmyard manure is considerably less (30 per cent) than that of sodium nitrate.

An analysis of the development and composition of the wheat plant as affected by fertilizers has produced results of no less interest. Up to a certain point increased nitrogen has no effect on the composition of the wheat plant or on its habit of growth, and this point can be carried to a higher level of nitrogen supply by giving potash and phosphates. Finally, however, a point is reached at which nitrogen is in excess; the leaves become liable to fungus attack, the crop tends to lodge, and the straw remains green for a longer time and dries slowly at harvest. The variation of composition with season is much more marked than with manuring. Milling and baking tests show no significant effect of treatment on quality, and the recent claim that wheat grown with farmyard manure is of better nutritive quality than wheat grown with artificial fertilizers is not supported by the Broadbalk samples as regards vitamin B.[1]

Continuous wheat cultivation has not found favour in England for a variety of reasons. Nevertheless, where a good outlet can be found for the straw, very frequent wheat growing has proved profitable provided the manurial system be sound; it has, in fact, been followed by a number of farmers with success. It is at least quite clear that, should continuous wheat growing be taken up in England, these experiments at Rothamsted will prove of inestimable value. On one point they are especially conclusive. No amount of manuring and no elaborate care in cultivation will ever raise a second-class wheat field into the first class.

---

FORTHCOMING EVENTS

[*Meeting marked with an asterisk is open to the public.*]

Monday, May 12

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W. 7), at 5 p.m.—Sir Charles Arden-Close, F.R.S., Mr. F. S. Richards, Mr. Arthur R. Hinks, F.R.S.: "Map Projections and Sun Compasses".

Tuesday, May 13

ROYAL SOCIETY OF ARTS (at the Institution of Electrical Engineers, Victoria Embankment, London, W.C.2), at 2.30 p.m.—Lieut.-General A. G. L. McNaughton: "Research in Canada".

ROYAL INSTITUTION OF GREAT BRITAIN (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Dr. Alexander O. Curle: "Glimpses of 2,000 Years of Home Life: as Revealed by Excavations in the North of Scotland".*

INSTITUTE OF PHYSICS (London and Home Counties' Branch) (in the Lecture Hall of Messrs. Kodak, Ltd., Harrow), at 6 p.m.—Dr. C. Sykes: "Thermal Effects in Transformations in Metals".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN MECHANICAL ENGINEERING at the Leeds College of Technology—The Director of Education, Education Department, Calverley Street, Leeds 1 (May 19).

DEPUTY BOROUGH ELECTRICAL ENGINEER in the Electricity Undertaking of the Woolwich Metropolitan Borough Council—The Borough Electrical Engineer, Electric House, Powis Street, Woolwich, London, S.E.18 (May 19).

LECTURER (GRADE 2B) IN ELECTRICAL ENGINEERING—The Registrar, University, Leeds (May 19).

MANAGER OF THE WROUGHT LIGHT ALLOYS DEVELOPMENT ASSOCIATION—Mr. Eric L. Heathcote, Wrought Light Alloys Development Association, 25 Bennetts Hill, Birmingham 2 (June 7).

PROFESSOR OF MATHEMATICS—The Bursar and Deputy Registrar, University College of North Wales, Bangor (June 30).

GRADUATE TEACHER IN ENGINEERING at Kenrick Technical College—The Director of Education, Education Offices, Highfields, West Bromwich.

ASSISTANT ENGINEER FOR THE SUDAN RAILWAYS—The Controller, Sudan Government London Office, Oxford Hotel, 261 Clifton Drive South, Lytham St. Annes, Lancs. (quoting 'Assistant Engineer').

ASSISTANT ENGINEER in the Government of Zanzibar Public Works and Electricity Department—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1 (quoting M/9634).

TEACHER OF ENGINEERING SUBJECTS—The Principal, Technical School, Cole Street, Scunthorpe, Lincs.

THE SELECT COMMITTEE OF NATIONAL EXPENDITURE

WHILE the statement on science and the national effort which Lord Hankey made in the House of Lords on April 2 (see NATURE of April 12, p. 432) of necessity adds little to an earlier statement by Lord Chatfield last year, it gives an admirable reply to certain criticisms of the use being made by the Government of our scientific man-power, and with little supplementing could well be used by the scientific worker to educate public opinion as to the part which science is playing in our war effort. It was, of course, well-nigh impossible for Lord Hankey to cover the whole field in any detail in the time at his disposal, but there are at least two respects in which from the point of view of educating public opinion his statement might perhaps have been amplified.

In his reference to the achievements of Nazi Germany in the field of science, Lord Hankey contented himself with the assertion that our men of science are at least as good as his. Without adulation of our own achievements in this respect Lord Hankey might well have pointed out that the domination of science by the State under the Nazis and the proscription of freedom of thought and investigation, apart from racial persecution and discrimination, have not only robbed Germany of many of her ablest workers, but have also made German science static. As Mr. W. Kæmpffert points out in an article "Science in the Totalitarian State"*, while science can exist in a totalitarian regime, it will be a frozen science. Science can only be a powerful social force for good when the individual worker is permitted to enjoy the fundamental freedom of democracy—to work without intellectual restraint.

Lord Hankey might well therefore have referred more explicitly to the way in which the existence of creative science and an independent scientific outlook are bound up with the existence of democracy and have pointed to the decadence of science in Nazi Germany, as Dr. C. J. T. Cronshaw did in his recent address before the Society of Dyers and Colourists. Dr. Cronshaw made the important point that Germany is fighting this war on the technical progress and skill of a generation which is running out and which in calibre, training and experience is not by great lengths matched by succeeding generations. Bias and prejudice had destroyed progress.

Reference to the work of the Select Committee of National Expenditure would also have been appropriate and useful. There are in fact few bodies which are doing more to inculcate a scientific outlook and approach to the national effort than this Committee in its admirable series of reports. Its searching but constructive criticism is designed not merely to eliminate waste but also to encourage that impartial and comprehensive view of affairs which is of the essence of the scientific spirit. Tribute to such work in Lord Hankey's statement would not have been more appropriate than deserved. The Scientific Advisory Committee takes a narrow view of its functions if it fails to recognize the assistance it is receiving both directly and indirectly from this Select Committee.

The value of the latter's work is indeed cumulative, and the very existence of such a committee is striking evidence of the inherent healthiness of the democratic system and its capacity to rectify weaknesses or abuses, given the will or driving power. The impartial but severe and searching criticism of the Sub-Committee on Air Services, in the Select Committee's Ninth Report, of the Air Ministry's practice of price contracts for the preparation and construction of aerodromes, the equally severe condemnation by the Sub-Committee on Supply Services, in the Seventh Report, of the Ministry of Works and Buildings for the absence of unified control over constructional work, and also the strictures, amounting almost to censure, on the Ministry of Transport and other Government departments in the Eighth and Tenth Reports would not be possible under a totalitarian regime, with its stifling of independent judgment and impartial analysis. Such constructive criticism is at once the strength and opportunity of democracy, provided only its leaders and institutions are capable of profiting by criticism and applying it without prejudice and with firm resolution to the remedying of the weaknesses disclosed.

---

* *Foreign Affairs*, January, 1941.

These latest reports from the Select Committee, no less than the earlier reports, are in fact a searchlight on the position of and opportunity for scientific management in Great Britain. There are few factors more vital to the efficient conduct of our war-effort than scientific management, and if in his recent speech in the House of Commons Mr. Bevin did less than justice to some of the factors on the labour side which impede production, his indictment of management was fully justified in many quarters and is substantiated by evidence in these reports. There can be no place in our war-effort for management or directorates which wilfully ignore dearly purchased experience with regard to hours of work, the value of canteens and other problems in industrial psychology in which in the last twenty-five years so much work has been done by the Industrial Health Research Board, the National Institute of Industrial Psychology and by other bodies.

Many of the weaknesses which call forth the severest criticism of the Select Committee are due fundamentally to neglect of such experience or of established principles of management. It is indeed startling to find that it is still necessary to put emphasis on supervision, whether at the top to secure unified control, by the appointment of one man with the maximum authority to be in charge of each building or group of buildings in course of construction, or in the provision of skilled supervisory staff on the site. The neglect of management principles and experience thus revealed in the Seventh Report is exactly parallel with similar criticism of the Air Ministry's failure to inquire into the most economic management of labour and materials on the site, or to supply adequate supervision in aerodrome construction, and with the neglect in the exchange of technical knowledge which is the subject of comment in the same report.

The importance attached by the Sub-Committee on Air Services to the pooling of ideas and knowledge has a direct bearing on Lord Hankey's statement. It indicates at least one point in which there is some hiatus in the application of scientific and technical knowledge to the war-effort of the nation. A further point is indicated in the Sixth Report of the series, in which the Sub-Committee on Trade, Agriculture and Economic Warfare reviews the work of the Ministry of Agriculture and Fisheries.

The Sub-Committee has been impressed by the statement of witnesses that what is required to improve the standard of British farming is not so much further research work and the development of new scientific methods as the translation into practice of certain simple lessons already clearly taught by scientific study and by the experience of progressive farmers. This is largely the task of scientific exposition, to which the P E P Report on Agricultural Research in Great Britain directed particular attention in November 1938, and which was the subject of some of its most important recommendations. The great need is to find sufficient numbers of men combining knowledge with practical experience to give this instruction and advice by personal visits.

Beyond this, however, the Sub-Committee points out that action is required to ensure getting full value from the County War Committees' powers. Instructions should be issued to ensure that valuable data resulting from the Committees' experience are recorded and collated, that the experience gained and ideas developed by one Committee are made available to others, and that the fullest advantage is taken of experience gained from direct farming by the County Committees. Considerable importance is also attached to the strengthening of the Economic Intelligence Division of the Ministry, both in staff and in authority, as the chief safeguard for continuity of policy and for holding the balance between contending enthusiasts.

These recommendations, designed to facilitate all the resources of science being readily available for the solution of war-time problems, well illustrate the way in which the Select Committee's reports supplement the picture of science and the national effort given by Lord Hankey. There is, however, one further aspect, particularly stressed in this Sixth Report, to which Lord Hankey referred, in which the reports and the statement are complementary. Lord Hankey referred finally to the way in which British men of science and the scientific resources of the Empire and of the United States are building scientific equipment destined to play an ever-increasing part not merely in our war-effort but also in the period of reconstruction that must follow. The Select Committee in its Sixth Report stresses the importance, as the War proceeds, of shaping plans for post-war policy with progressive definition.

It is pointed out that the two issues—war-time food production policy and long-term agricultural policy—are closely interlocked. A complete review of the opportunities for improving the fertility of the soil would be valuable both for war and for post-war purposes, particularly a review of what can be done to improve drainage. Again, the general method for giving a sound foundation to the agricultural industry might well be the same for both the war and the post-war periods, although their detailed application might differ. The essential need for creating confidence in post-war policy as a measure for encouraging the war effort means that in agriculture especially the two must to some extent be considered together.

To this end the Report suggests that the Ministry might collect and prepare adequate material, to be issued in due course as a White Paper, so that when the appropriate time comes Parliament would have before it the basis for a comprehensive plan for maintaining, after the War, a healthy and well-balanced agriculture as an essential and permanent feature of national policy, in accordance with the Ministerial statement of November 26. It is only by continuity of policy that confidence can be created and waste avoided.

Similarly the investigation of deficiencies in the system for the distribution of vegetables which may both lead to waste and discourage production should yield results as valuable after as during the War. Again a comprehensive plan for crop production must take account not only of agricultural conditions and the need for balanced production with proper rotation of crops but also of the nutritional requirements of the country and the nature and quantity of imported food supplies which will be available. The Scientific Committee which has been set up by the Government to advise upon these problems may well lead to marked improvements in the nutrition of the nation after as well as during the War, and here again, the Select Committee observes, it may be possible to pass, as experience is gained, from the stage of tentative direction to the formulation of a definite and comprehensive plan.

These reports of the Select Committee accordingly make heartening reading in days when sterner sacrifices and more strenuous efforts are being demanded of every citizen. They show that scientific minds are resolutely probing into weaknesses and inefficiencies in our war-effort and pointing the way to eliminate them. Still more, they afford solid and renewed grounds for confidence that the sacrifices and effort demanded of us will not be in vain. It is not merely that obstacles to progress are being loosened and the way cleared for advance. In the midst of our war-effort there are slowly but progressively emerging the lines of policy and the plans which will shape a new era in which science may prove itself a growing social force for good in the democracies it has helped to victory.

THE FEEDING OF LIVESTOCK

The Principles and Practice of Feeding Farm Animals

By E. T. Halnan and Frank H. Garner. Pp. x+359+8 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1940.) 15*s*. net.

THE stress of totalitarian war has quickly revealed the fundamental instability of systems of livestock husbandry which are largely dependent upon supplies of imported feeding-stuffs. In an industrialized State, concerned to maintain a large export trade and with a large investment of capital in the less-developed regions of the world, it is inevitable that the national agricultural economy should provide for a considerable absorption of imported grain, oil-seeds and other primary produce. If this absorption has developed beyond the limits of security for war conditions, the blame, if blame there be, cannot be placed upon the farmer, since he has little option but to adjust his system of husbandry to the economic environment created by national and international policies.

The direct responsibility which he must accept is that of avoiding waste in his use of feeding-stuffs, especially when, as now, both private and national interest make this imperatively necessary. That the avoidance of waste is to his own material interest at all times is plain, but the precept is nevertheless all too often honoured 'in the breach' on the farm, partly through the practical impossibility of maintaining a precise control of supplies, and partly through the natural repugnance of the good stockman towards any stinting of food to his charges below the full limit of their appetites.

That the physiological economy of utilization of food tends to fall long before the extreme limits of appetite are reached has been abundantly demonstrated, and more often than not the same is true of the financial economy of the process. In so far, therefore, as the supply of food to the animal is based upon economic considerations the need for controlled feeding is obvious, and much of the effort of the nutrition investigator engaged upon agricultural problems has been directed towards ascertaining for the different classes of livestock the levels of food-supply at which the maintenance requirements and productive activities of the animal can be covered with minimal waste of food. Such 'feeding standards' have been tabulated from the earliest days of agricultural nutrition science, but it is only within the present century that they have attained a sufficient degree of precision and conformity with farm experience to secure the confidence of the farmer and his practical advisers. Towards this end the spread of technical education among farmers through the improved training of new recruits and other forms of educational effort has also made a powerful contribution. But for this it would have been impossible to apply to the industry a national system of rationing of food supplies so closely adapted to its varying needs as that now in operation.

Although much of the newer knowledge of nutrition has little practical import for the greater part of our animal husbandry, it is none the less necessary for the farmer and student to be adequately informed as to the full range of the fundamental requirements of the animal. At one extreme where natural foods and outdoor environment enter largely into the system of management, the stockman will have little concern except to ensure adequate supplies of nutritive energy and of protein, and will have little anxiety as to the concurrent supply of vitamins and essential mineral elements. Where, on the other hand, the system is highly 'intensive' and artificial in character, as in the case of a large part of our pig and poultry husbandry, and some part of our dairy husbandry, the full range of nutritional knowledge must be taken into practical account.

Although the British agricultural research organization has made a large and valuable contribution to this knowledge it has produced as yet only a very modest output of literature designed to meet the needs of the farmer and agricultural student. So far as the mere exposition of fundamental principles and the advance of scientific knowledge is concerned these needs are adequately met by American and Continental literature; but the discussion of their application in British farm practice can obviously only be dealt with effectively by authors who are familiar with the systems and environmental conditions under which livestock management is conducted in Britain. The required amalgamation of science with practice is perhaps most effectively met by collaboration of nutrition scientist and agriculturist, supplied most appropriately in the present case from the personnel of the Cambridge School of Agriculture, which for the past thirty years has been a leading centre of agricultural nutrition research. One might have expected the Cambridge authors to have been primarily concerned to cater for the needs of students; but in terms of printed pages and detail of exposition this present volume is more largely a practical manual than a scientific text-book. In the introductory section dealing with the principles of nutrition a high degree of compression has been exercised and not a single reference to original literature is cited. It will not satisfy the student and will probably be found rather difficult reading by the farmer not well versed in science. What is dealt with most fully and admirably throughout the whole work is the modern technique of control of rations to secure efficiency with economy. On this aspect of the subject it gives the best exposition yet available and will form the standard work of reference for student and farmer alike. One could only wish that the plain application of science had not been so largely obscured by the inclusion of a mass of practical detail that requires no new exposition.

In their attempt to cater for both student and farmer in one volume the authors have certainly come near to success, except for the needs of the more advanced student. Theirs is not the text-book for which degree and diploma students have long been waiting; but it may be warmly recommended to the larger farming public which is more concerned to know how to apply modern methods than to understand the scientific basis upon which they rest.

Charles Crowther.

THE GENESIS OF PRINTING INKS

Printing Inks

Their Chemistry and Technology. By Carleton Ellis. Pp. 560. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1940.) 42*s*. net.

THE printing-press has without a doubt been one of the greatest factors in the progress of man. The name of the supposed inventor of printing from movable type is known to all informed people, but it is now fashionable for scholars of history to dispute the claim of Gutenberg and give the credit to one Coster of Haarlem. Apparently the most convincing German records discovered at Mainz in 1740 are held to be forgeries. The British at least can still pay tribute to Caxton for his share in bringing the printing-press to our shores.

The press needs paper and ink besides type to produce a book, and it is a proper question to ask who invented ink. All we know is that the forerunners of ink and paper were not developed prior to 4000–2000 B.C. simply because there was no need for them. Writings were few, slaves were many; characters were incised in stone tablets or marked on clay which was later baked in kilns.

The Egyptians used dyes to colour the engraved markings to make them more conspicuous—a suspension of coloured charcoal and gums in water. As trade expanded there was need for a more portable and convenient writing material and papyrus sheets came into use as long ago perhaps as 2500 B.C. Later papyrus met with competition from parchment and vellum, but not until the third or fourth century A.D. This delay may have been because leather was in demand for many other uses.

The earliest inks used on papyrus consisted of soot or some other finely divided form of carbon suspended in a varnish containing a drying oil; for red inks iron oxide was used. Such pigments have retained their colour over a span of almost five thousand years. Mention is first made of inks which penetrated the body of the sheet rendering erasure much more difficult about A.D. 50. Pliny apparently used a suspension of lamp black and copper sulphate in water.

Indian ink, which of course has nothing to do with India, was developed by the Chinese at the beginning of the third century. The chief ingredient was lampblack, pounded through fine silk to reduce its size; this was made into a paste with glue, water, the whites of several eggs, cinnabar and musk. After prolonged grinding in a mortar the ink was cast in sticks and was sold and used in this form until the reservoir pen ousted ink from the writing-table. Kipling records that he used it at Bateman's in preference to any other ink; my father always had a stick on his table and a small round white dish in which to rub it down in water for use on special occasions. The art of ink-making became very widespread and important in China, and Indian ink was long recognized in Europe as the finest quality of black.

The quill pen which permitted the use of a more liquid ink was the last invention of note before the dark ages following the fall of Rome. For five hundred years or longer progress was left to the monks. Gall inks came to Europe from Arabia about A.D. 1100 and gained increasing popularity in the monasteries. All this time there was no call for the multiplication of documents: such copies as were required were made by the monks in their abundant leisure, but by 1400 the invention of printing was at hand. Carved wood blocks were cut for the illustration of the text of a scribe who filled in the written matter by hand, and it was not a far cry to place the text on the same block. The next step was to develop the art of printing from movable type.

The earliest printing ink contained sulphate of iron in combination with vegetable astringent matter and with very little carbon. Before long inks made of linseed oil and lampblack, applied to the surface of the type with inked pads, were used. About 1823 an ink formula consisted of linseed oil, rosin and hard soap added so that the ink would leave the type easily. To-day in printing inks the craftsman ink-mixer has given part-place to the man of science.

This book takes 450 closely written and printed pages to tell us all about vehicles and pigments, driers and modifiers. There are also very many special types of inks which may be employed on a great variety of materials often at high speeds of printing. There are many ink problems in the production of a newspaper at high speed on paper of poor quality—a discussion of these takes up many pages. In short, it is possible to write an erudite and practical monograph on the subject of printing inks alone. The name of Carleton Ellis is a guarantee that the work is accurate, thorough and comprehensive. He has enriched so many fields of applied chemistry by his writings and it is a melancholy thought that this must be the last, for he recently died. The printed book, magazine or newspaper is the commonest thing in the land; to be bought for a copper or two, glanced at and thrown away. Few readers spare a thought to the lives and ingenuity devoted to giving them type, ink and paper; least of all do they realize how much applied science, peaceful science is responsible for their merits and cheapness. If NATURE had to be produced by the monks and the few copies were handed from one to another, there would be perhaps more appreciation of its contents, but its missionary value would be less.

Carleton Ellis has done good service to the end of his useful life by producing this monograph.

E. F. ARMSTRONG.

SOIL FERTILITY AND NATIONAL HEALTH

An Agricultural Testament

By Sir Albert Howard. Pp. xvi + 254 + 13 plates. (London, New York and Toronto: Oxford University Press, 1940.) 15*s*. net.

THE strong criticisms of the agricultural practices in many countries at the present day, and of the aims and technique of modern agricultural research made in this book, are based upon the author's work and experience during a period of forty years in the West Indies, India, and Great Britain. It is with the process of manufacturing compost evolved in the Institute of Plant Industry, Indore, Central India, between the years 1924 and 1931, that the name of Howard is more particularly associated in agricultural circles.

The key of the arguments used in these criticisms is stated in the following quotation from the chapter on the nature of soil fertility: "The wheel of life is made up of two processes—growth and decay. The one is the counterpart of the other. . . . Humus is . . . an essential material for the soil if the first phase of the life cycle is to function. . . . Its presence in the soil is an essential condition for the proper functioning of the second contact between soil and plant—the mycorrhizal relationship".

The methods adopted to maintain soil fertility in China, and under the old mixed farming systems of a large part of Europe, are quoted as examples of successful stabilization of agriculture without loss of fertility, in contrast to the "soil mining" methods characteristic of "Western agriculture", to which the United States Soil Conservation Service is now devoting so much of its attention.

The book as a whole and the chapter on present-day agricultural research in particular contain a great deal of criticism of the "NPK mentality" which originated with Liebig in 1840, and was revived, following a temporary lull, with great vigour in the years following the War of 1914–18, when the factories then engaged in the fixation of atmospheric nitrogen for the manufacture of explosives had to find a new market.

The agricultural literature during this last period is full of the results of innumerable field experiments "bewildering in their volume, their diversity, and often in the conclusions to be drawn from them. By a judicious selection of this material, it is possible to prove or disprove anything or everything". Mathematics was introduced to give a greater measure of reliability, field plots were replicated and randomized, and the figures subjected to a rigid statistical scrutiny. During this "age of the manure bag", there has occurred an increasing loss of soil fertility, an increase in crop and animal diseases, a decrease in the standards of human health and nutrition, and the apparent futility of the work of plant breeders, who produce new varieties with an increased yield which can be obtained only at the expense of more soil capital.

The present situation must be saved by the community as a whole, if a *C*3 population is not to be created, "fed on improperly grown food . . . bolstered up by an expensive system of patent medicines, panel doctors, dispensaries, hospitals, and convalescent homes". In the United States alone it is estimated that no less than £700,000,000 a year is spent on medical care.

Much of the book is devoted to a description of the actual technique involved in the Indore process, and to its practical application and development. The crops considered are tropical or subtropical in nature, but there are also interesting comments on grassland management, orchard management and similar subjects.

It is probable that many of the criticisms and provocative statements made in this book will be answered to some extent by the major trend in world agriculture towards the increased use in many countries of grasses and legumes, and particularly of the temporary ley, in farming rotations. In this way, fertility, structure and organic matter content of the soils, whether formerly in permanent grassland or mono-cultivation, will be greatly improved in a healthy way, without the need for excessive use of the chemical dopes which, according to the author, are poisoning the nutrition of crop plants, domestic animals and human beings.

The other important method of returning organic matter to the soil, namely, the practice of green manuring, is approved of, if the crops grown for this purpose are cut and used to provide material for composting, leaving only the root system to decay in the ground and thereby considerably reducing the burden on the soil.

R. O. WHYTE.

COLONIAL ADMINISTRATION

Democratise the Empire
A Policy for Colonial Change. By W. M. Macmillan. (The Democratic Order, No. 6.) Pp. 64. (London: Kegan Paul and Co., Ltd., 1941.) 1s. net.

ON the first page of this arresting, and indeed, challenging pamphlet, the author says, "on the face of it, Empire, the government of weaker peoples by a power outside themselves, is the very antithesis of the Democracy for which we stand". The truth, of course, is that in a too rapid development towards independence there is great danger lest a country, lately brought within the orbit of modern civilization, be controlled by the well-educated few who will not be subject to the checks of an informed and articulate population. In such checks lies the real strength of a democratic constitution.

Prof. Macmillan recognizes this, but he maintains that the pace has been too slow and that British Colonial policy has suffered from *laisser-faire*, particularly in the economic sphere, one on which he is very competent to speak and on which he has many interesting things to say. He praises the 'tripartite Co-operation' of the cotton-growing enterprise in the Sudan, whereby the Government met the cost of a large-scale irrigation scheme, the Sudan Plantations Syndicate provides expert management and the peasants receive a fixed proportion of the price of the cotton when sold. This principle, he says, might be applied to mining, public utility services, plantations, and so on. Some of the profits might be returned to the people in the shape of improved welfare services.

There are many who would also like to see experiments made in 'co-operation' (in the technical sense) especially among the inhabitants of the rural areas, combined with a scheme for the education and development of the people based on their indigenous culture and traditional way of life. Such experiments might well follow the suggestions contained in a memorandum emanating from the Colonial Office Advisory Committee and entitled "The Education of African Communities".

It is impossible in a short article to discuss the many aspects of the Colonial problem upon which Prof. Macmillan touches. This small book is packed with interesting and suggestive comments.

The main theme, however, is political structure. He is somewhat critical of 'Indirect Rule', which is now an accepted principle of government in some of our Colonies. He recognizes its value as a form of local government, provided that it is not considered "as the last word in the Government of any people". In due course the people will rightly demand control of the non-native supreme authority, and he asks what machinery we can provide but representative institutions.

The real justification for 'Indirect Rule' is that it represents an important educational stage. In its present form it is a means and not an end in itself. Moreover, 'Indirect Rule', adopted in many African Colonies, cannot be applied to such Colonies as the West Indies, where tribal tradition and authority do not exist.

If 'Indirect Rule' is to be not merely a temporary expedient but also to supply the basis of future Government, there must be clear vision of the end in view and the means for attaining it. It is for the British Government to see that the successive stages in each Colony are reached as soon as local conditions make such advance possible. That the British Government is prepared to shoulder this responsibility is indicated by the steps already taken to make a survey in each area of the political framework, economic possibilities and the various human problems involved, as a first step towards formulating a progressive policy. The immediate goal appears to be gradually to develop, from indigenous institutions, forms of local government embracing far larger areas and sections of the population than those from which they have sprung, and federated under a central council which derives its authority from them. The people themselves will eventually have to decide in the light of experience gained during this educational period, to what extent modifications suggested by European forms of democracy may be desirable.

It would be out of place here to mention international problems involved in our own Colonial policy, but there is one outstanding difficulty within our boundaries which must be faced. It is that of reconciling the natural aspirations of the African population with the claims of Europeans in areas of white settlement. The problem is one of immense difficulty, but if handled firmly and handled quickly, there is no reason why it should prove to be insoluble.

E. R. J. HUSSEY.

INDUSTRIAL PSYCHOLOGY FOR FOREMEN

The New Techniques for Supervisors and Foremen
By Prof. Albert Walton. Pp. vi+233. (New York and London : McGraw-Hill Book Co., Inc., 1940.) 17*s.* 6*d.*

THIS is a remarkable book written by an author of remarkable experience. "The new techniques" which it describes, in elementary fashion, are those of industrial psychology. "Management," he says, "faced with the absolute necessity of adopting the new techniques" crudely employed by the early efficiency engineers in the United States, "yet finding that their introduction was always the signal for labor troubles, finally recognized that the problem was, in its essence, a psychological one. They turned to the university psychologists and asked them what could be done about it. Bred in the cloistered peace and quiet of their campus laboratories, these psychologists were not of much assistance. They had no experience in the workaday world, and most of them were not inclined to venture into it to attack the monumental problem which they had been asked to solve. Here and there a bolder spirit was found who could see not only the tremendous interest which might be aroused by work in the field but the vital necessity for finding a solution. . . . A few pioneers took up the work and soon found they had entered a rich field in resources and awaiting only careful research to yield a wealth of practical values not only to the industry but to general psychology itself" (pp. 104–5).

Prof. Walton was not one of these academic psychologists. He was more than forty-five years old when he entered the University of Washington in Seattle as an undergraduate student in psychology. He had, when a youth, graduated at Cornell as a mechanical engineer, after which he was engaged for twenty-five years, he tells us, "in the field of industrial engineering, part of the time with such organisations as Westinghouse and General Electric, . . . and part of the time as a consulting industrial engineer with my own office and private practice" (p. 1). He regarded his new career of a psychologist as one "in which age would be no barrier but rather an advantage". From Seattle, after taking his master's degree, Prof. Walton proceeded to Stanford University where he taught classes in psychology, took his doctor's degree, and then served as instructor in psychology, until he accepted his present post of assistant professor at the Pennsylvania State College. Here he has been teaching industrial psychology in "foreman training classes in the various industrial plants around Philadelphia and the territory within a hundred miles of the city" (p. 3). Thus he "came into the field of psychology after a quarter of a century in the active world of industry, looking", as he says, "for something usable, something that I could apply to my own situation" (p. 3). The present volume virtually contains what was covered by this course in industrial psychology for foremen, and concludes with an appendix giving notes of supplementary discussions attended by those who had already been through the earlier course.

There are many details in this book with which the 'pure' psychologist may not agree. He will object to the definition of psychology as "the study of the mind, which is what we think with" (p. 8) ; but the author fully realizes the important part played by the feelings, drives, motives and by what he calls "intents". He will object to the statement—"The only way we know anything about the mind is by what the body does" (p. 11) ; but the author is clearly far from being an extreme 'behaviourist', for although he urges that "interviewing is not a satisfactory way of securing an estimate of a man's abilities" (p. 19), possessing, as it does, the weakness of allother 'subjective' methods of investigation, he concedes later that "in no test program with which we are familiar has it been proposed to do away with the interview entirely and to place sole responsibility on tests. The test is to serve as an aid to the personnel department and to the supervisor" (p. 66). The psychologist may also cavil at the statement that instinctive reactions "and a few reflexes are all the child has at the outset. All else is learned" (p. 26), and at the exaggerated distinction drawn between what is innate and what is acquired. But it becomes clear that this and many other criticisms arise mainly from the need for extreme simplicity of initial statement, having regard to the previous education of those whom the author is addressing.

It is from this point of view that the book should be judged ; and no fair critic can read it without admiration and appreciation of its almost perfect fitness for its purpose. It should be read by every progressive departmental manager and intelligent foreman in English-speaking countries.

C. S. MYERS.

PHARMACOLOGY WITH GRACE

Pharmacology
By Prof. J. H. Gaddum.. (Oxford Medical Publications.) Pp. xv+408. (London: Oxford University Press, 1940.) 17*s.* 6*d.* net.

It is characteristic of the author of this book that he should call it by the unencumbered title "Pharmacology"; not "An introduction to" or "A Text-book of" or "Essentials of" or any other of the common attempts to avoid a simple statement of what a book contains.

This directness is evident throughout the book, which is noteworthy in the first place for the excellence of its literary style. Quiller Couch in "The Art of Writing" proposes that writing should be appropriate, accurate, perspicuous and persuasive, and has explained those terms in a way which makes it clear that if there is one form of training which should make better writers than another, it is scientific training. Certainly those engaged in scientific research have a constant stimulus to be accurate and perspicuous; if they cannot make their deductions clear to others, they do not understand them themselves. The processes of Nature which they study should make them modest and their language therefore appropriate, and their repeated failures, by developing their humour, should give them persuasiveness or charm.

It is impossible to refrain from quoting odd sentences from different parts of the book which indicate how pleasant it is to read. Speaking of the use of tetrachlorethylene for the treatment of hookworm disease, Gaddum says: "Many thousands of men and women have been treated with it; there have been no fatalities among the patients, but unfortunately no one knows how many fatalities there have been among the worms." In discussing sulphanilamide, used for its lethal action on streptococci and other bacteria, he gives a list of twenty-three names under which this one substance is sold, and adds: "There is no point in memorizing these names, which are given as an awful example of the ingenuity of manufacturers."

Perhaps the best one is the explanation of frequency distributions, which begins: "A certain rich man had 64 friends and gave each of them 100 marbles." It may be explained that the friends then toss coins, the loser forfeiting a marble to the winner, and continue this process six times, to furnish a diagram showing the distribution of the marbles among friends who toss fairly.

Pharmacological teaching has slowly progressed from materia medica and doses to the action of substances in the body. The teaching is still given in many schools by those who have little acquaintance with laboratory work, so that students remain ignorant of the methods which are introducing so many new remedies into medicine, and are also unable to form any opinion of the justice of the claims made by advertising manufacturers. The distinctive feature of Prof. Gaddum's book is that it attempts to fill this gap and to give instruction in the methods actually used by experimental workers. It stresses the steps which should precede the introduction of new preparations into the hospital: "In 1937, for example, diethylene glycol was introduced as a solvent for sulphanilamide, and 71 people were killed. This accident could have been avoided if a few simple toxicity tests had been carried out." Evidently, this book is suited not only to medical students and doctors, but also to chemists engaged in the manufacture of new remedies. If they are to be successful they must understand what the pharmacologist can do, and how much labour is involved in doing it.

Special mention must be made of the chapter on general pharmacology at the end of the book. It contains a very clear exposition of methods of calculating experimental errors, which is short and valuable for those with no inborn or acquired mathematical appetite.

Many features of the general arrangement of the book are original and seem an improvement on the usual arrangements. In the preface it is stated that "the information sought by examiners has been included as completely as possible". No doubt opinions will differ whether sufficient attention has been paid to this or that section, but it was certainly right to make the book no longer than it is. Since it would not be fitting to conclude without some positive criticism, it may be suggested that the view that insulin is concerned in the combustion of dextrose has been abandoned many years ago; the diabetic needs less insulin when he plays tennis.

Let us, however, congratulate the author (and the publisher) on this attractive, well-illustrated book.

J. Harold Burn.

THE PHYSICS OF AIR RAIDS*

BY PROF. J. D. BERNAL, F.R.S.

A GREAT deal of the terrifying effect of bombs has been due to our lack of knowledge of the processes that take place. It is naturally difficult to study events which take place with the rapidity and violence of explosions, but it is not impossible, and thanks to the work of a large number of physicists in many countries before the War, and particularly in Great Britain during the War in the laboratories of the Department of Scientific and Industrial Research, we may say that the main features of the physical processes involved in explosions are becoming well understood. Naturally it is impossible to give here more than the broadest outlines of our present knowledge, both on account of its intricate nature and even more because of the requirements of secrecy.

Most of the effects of explosives on materials can be best understood by considering the explosive to generate a wave of extremely high intensity travelling through the body at a very high speed. Normally, mechanical disturbances travel in materials at the speed of sound, a speed which is determined by the square root of the ratio of the density of the body to its elasticity. Where the density is large and the elasticity small, waves travel slowly, and vice versa, the limits being between about 500 ft. a second in carbon tetrachloride vapour to 17,000 ft. a second in steel. For the high pressures which exist near explosions, much greater velocities occur. This is because the elasticity of bodies depends on the pressure; the interiors of atoms are more rigid than their outer surfaces. On intense compression a high elasticity and therefore a more rapid wave is produced. This is, of course, much more marked in gases than in solids and liquids. The velocity of sound in water may change from 6,000 to 12,000 ft. a second in the neighbourhood of an explosion, but that in air will change from 1,000 to about 20,000 ft. a second.

There is also a change in the character of the wave. High-pressure waves have not the smooth wave form of ordinary sound waves. Instead, the pressure in front of the wave rises immediately to its highest value and then falls off gradually and is followed by a phase of less than atmospheric pressure or suction (Fig. 1). The generation of this steep-fronted or shock wave is very similar to that of the waves which break on the sea-shore; the high-pressure phase of the disturbance, always travelling faster than the low-pressure phase, gets to the front, just as the top of the wave on the sea-shore, being held back less than the base by the friction of the sand, moves forward and ultimately breaks the wave. The shock wave is always breaking, as the free front portion is losing energy more rapidly than that behind and consequently, quite apart from the spreading of the wave, it is always dying down, most quickly, of course, nearest the explosion, and ultimately it degenerates into an ordinary sound wave.

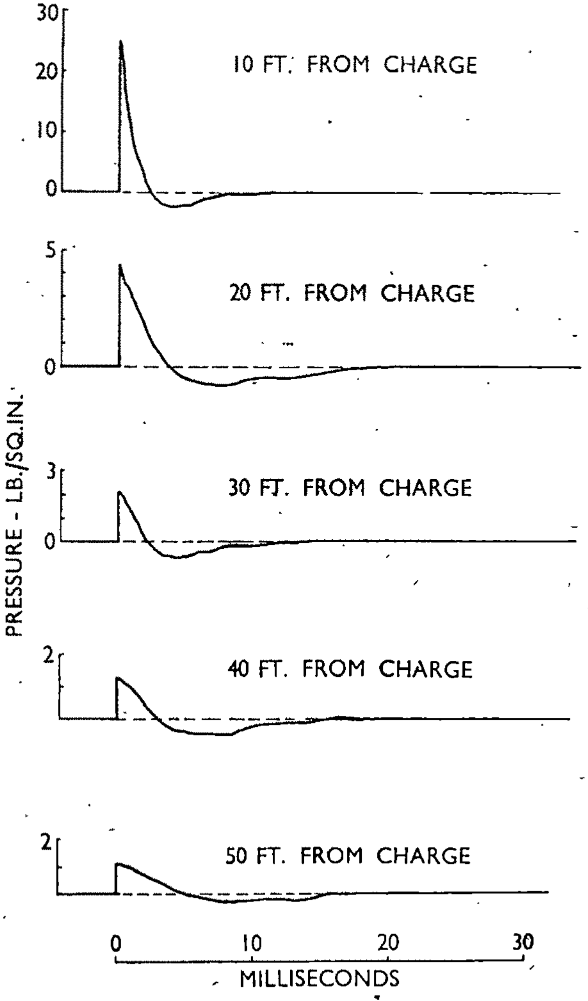

Fig. 1.

PRESSURE-TIME CURVES OF BLAST FROM 2-LB. CHARGE OF BLASTING POWDER.

---

* From a special afternoon lecture delivered at the Royal Institution on December 3.

The shock wave in air is what is usually known as blast and is responsible for most of the slighter effects of air raids, such as breaking of windows. The pressures needed to do this are not very considerable. Pressure peak values of 1–10 lb. per square inch, or less than an extra atmosphere, are able to break most windows, but peak pressures have to rise to about 100 lb. per square inch, or 6 atmospheres, before human beings are endangered, and this only occurs very close to explosions, so that in fact very few people are directly injured by blast. The shock wave, however, is not only an increase in pressure. Immediately behind the wave front the air is moving forward and there is an initial forward push followed by a backward pull. This, of course, can move loose objects about and throw people down or throw other things on top of them. Most injuries due to blast are only secondary in this sense and usually not very serious.

Fig. 2.

The freakish effects of blast on windows are not only due to the great variety of windows used. The shock wave behaves like any other wave in that it is reflected with more or less absorption from everything that it strikes. In streets, particularly with tall houses, this reflexion is almost complete. Consequently, a bomb exploding in a street sets up a series of reflected waves which at a considerable distance are like a periodic disturbance. If it happens that a window has a similar natural frequency, this periodic disturbance may break it by resonance. Consequently, isolated windows are often found broken at great distances from bombs.

Another so-called freak effect is due to the fact that a shock wave in a narrow street is reflected in a different way from the opening at the top of the street. A compression wave travelling in an open-ended pipe produces, when it reaches the end, a reflected suction wave, as the air having been driven out of the pipe a temporary vacuum is left behind. When this happens in a street, the reflected suction wave may be much stronger than the original suction wave of the bomb and may produce violent effects on windows and doors in lower stories, drawing them out towards the street.

A shock wave behaves in a characteristic way towards limited obstacles. Ordinary sound waves throw shadows only from the largest obstacles, such as hills or high buildings, because their wave-length is of the order of 10–100 ft. A shock wave, strictly speaking, has no single wave-length but a number of wave-lengths. The sharp high-pressure part has a very small wave-length and the tail suction part has a very long one. Consequently a shock wave passing through an aperture or round an obstacle is changed in character. Roughly speaking, the pressure part goes straight and casts shadows, whereas the suction part travels round corners without any difficulty. Thus behind a wall the pressure part of the wave may be cut down to about a tenth without making any difference to the suction part. This is very useful, as it has been shown that it is the pressure part of the wave that is responsible for most physiological damage. To have even a small garden wall between oneself and the bomb is practically to be secure from direct effects of blast. On the other hand, an open doorway is a danger and the necessity of putting baffles in front of Anderson shelter entrances applies to the blast as much as it does to the splinters.

Much of the terror attached to bombs has been due to stories of people being killed at great distances, without any physical injuries, by the mysterious effect of blast. Investigation has shown that the effect of the blast wave is that of a simple blow on the body. Most of the body is solid; the only empty parts are the lungs, and the effect of blast is essentially to bruise the lungs through the chest wall. This is effected only by the pressure part of the wave; the suction has no effect. Fortunately lungs will stand a great deal of bruising without permanent injury, and though quite a number of blast cases have occurred, most of them have recovered. Now that the nature of the injury is known, they can be treated as non-infected pneumonias, which, in practice, means only rest in bed.

Apart from blast, the main damage produced by bombs is due to splinters and earth shock. When a bomb bursts, the case first swells and then breaks up in a way very similar to the bursting of a gas cylinder under excess pressure. Failure takes place in tension along planes at 45° to the bomb surface, yielding angular fragments which are driven forward by the expanding gases. They therefore have very high velocities up to about 4,000 ft. a second and consequently have very considerable penetration into materials. The fragments are of all sizes, ranging from lumps of 40 lb. or more down to the most minute dust. As a result of experiments largely carried out since the War began, we are beginning to understand the mechanism of penetration of these fragments and the best ways of stopping them. Luckily the cheapest materials are, in fact, very effective. Three feet of sandbags have stopped any small fragment that has occurred in this War, and 13½ in. of brick will stop all but the biggest.

Only a proportion of bombs actually explode on the surface, usually on streets or concrete slabs; the great majority penetrate either into buildings or into the ground. The characteristic crater is that produced by a bomb exploding about 10–20 ft., according to size, underground. The damage done by such bombs is not due either to blast or splinters, but to the effect of the explosion on the earth. When a bomb explodes in a dense medium, such as soil, it produces a shock wave travelling at velocities which depend on the nature of the soil. As all soils get more elastic as they go deeper, the shock wave travels in a complicated way; it is reflected from the lower levels, and at distances of more than 100 ft. has already become a complex train of waves very similar to those found in earthquakes. Such waves can shake down buildings in a somewhat capricious way, depending on the natural frequencies of the building in relation to that of the waves, but generally speaking only old or badly built buildings are affected.

The most serious effects of ground shock are those nearer to the explosion, and are not due to the shock wave but to the bodily movement of the earth near the bomb. After explosion the explosive gases push the earth aside, forming an initial sphere of expansion. The displaced earth is moved outwards and quite considerable displacements occur. The displacement is partly elastic and partly plastic. The earth may be moved some inches and come back to within half an inch of where it started. This earth movement is, of course, mostly dangerous to underground structures. It is not so much an instantaneous blow as a steady pressure exerted for a time of the order of 0·1 sec. It is least effective on structures which can yield to such pressures without breaking. One of the main advantages of the Anderson shelter is its flexible character. This earth movement is usually responsible for the breaking of gas and water mains by bombs.

When the shock wave from an underground bomb reaches the surface, it is reflected as a tension wave, and if it is strong enough the ground cracks and a conical 'scab' is formed which is projected upwards, usually breaking up and leaving the characteristic crater behind. The observed crater, of course, is always complicated by the presence of material which has been thrown out and fallen back into it. The true crater is usually almost twice as deep. If the bomb is too deep, the breaking of the surface does not occur; it is simply heaved up and drops back more or less into place. This is called a 'camouflet'. Such camouflets are usually of little importance, except that they may be mistaken for unexploded bombs.

When a bomb strikes a building the effects are naturally complex, but they depend on relatively few principles. When a bomb explodes in a house its primary effect is to cause a blast wave which, meeting walls, blows them out. The effect is greater than blast in the open because the waves reflected from other walls add their effect to that of the initial blast, producing a more prolonged pressure and consequently a greater outward momentum. Except in very large halls or sheds, this blast pressure is sufficient to break the wall and project a considerable portion of it clear of the building. What happens afterwards depends on the type of the building. In favourable cases the only result is to form a hole in one or more external walls, the remaining part of the building holding together. More often the damage to the walls causes partial or complete collapse of the building. With steel-framed or reinforced concrete buildings the frame prevents the falling of the upper part of the building and holds up the comparatively small load produced by the immediate effects of the explosion.

This outline of some physical aspects of air-raid damage shows that we have a quantitative picture of the dangers of raids; this is the first step in providing rational means of minimizing them.

REGIONAL AGRICULTURAL LABORATORIES IN THE UNITED STATES

By Dr. R. O. Whyte

Imperial Bureau of Pastures and Forage Crops

DURING the past five or six years, a major development has been taking place in agricultural research in the United States, which should have a considerable effect on the rate of progress to be expected in several important problems, and on the number and scope of scientific papers published.

This development may be said to have originated officially with the signing of the Bankhead-Jones Act by President Roosevelt on June 29, 1935. This Act provided for substantially increased Federal aid for fundamental agricultural research, agricultural extension and land-grant college instruction.

The appropriations granted by Congress were 980,000 dollars for land-grant college instruction, 8,000,000 dollars for agricultural extension, and 1,000,000 dollars for agricultural research; under a sliding-scale arrangement these amounts might be increased to an annual maximum of 19,480,000 dollars by the beginning of the fiscal year 1940.

As regards agricultural research, the Act contemplated enlarged activities by both the State experiment stations and the Federal Department of Agriculture. Sixty per cent of the amount provided was to be available to the States of the Union, and Alaska, Hawaii and Puerto Rico, the funds allotted being based upon the respective rural populations, and being conditional upon the provision from non-Federal sources of an equivalent amount for purposes of research and for the establishment and maintenance of necessary facilities for the prosecution of such research.

The remaining forty per cent of the research fund was placed directly at the disposal of the Secretary of Agriculture, who was "authorized and directed to conduct research into laws and principles underlying basic problems of agriculture in its broadest aspects; research relating to the improvement of the quality of, and the development of new and improved methods of production of, distribution of, and new and extended uses and markets for, agricultural commodities and by-products and manufactures thereof; and research relating to the conservation, development and use of land and water resources for agricultural purposes" (*Experiment Station Record*, 73, No. 3, 289–91; 1935).

This research was to be conducted by such agencies of the Department of Agriculture as the Secretary might design or establish, but one half of the special research fund was ear-marked to be "used by the Secretary for the establishment and maintenance of research laboratories and facilities in the major agricultural regions at places selected by him, and for the prosecution . . . of research at such laboratories" (*loc. cit.*).

All research by the Department authorized under the Act was to be additional to any provided by existing law, but the desirability of co-ordination of activities was particularly stressed.

So far, nine of these special regional laboratories have been organized, each one being regarded as a co-operative enterprise between the various States concerned, serving as a focal point for co-ordinating and integrating research in its particular problem in its own region, and carrying on basic research along certain lines not already provided for adequately. One of the important reasons for criticizing the organization of agricultural research in the United States, namely, the fact that the agricultural experiment stations of adjacent States situated in the same geographical or agricultural region were carrying out research on very similar problems with little co-ordination as between States, has now to a great extent been removed.

As will be seen from the account of the scope and location of the new regional laboratories given below, anything from eleven to twenty-five States are now co-operating with one or other of the laboratories; the boundaries of a particular problem or branch of agricultural research no longer coincide with State boundaries, but with the limits of the region to which the problem applies more particularly.

The fundamental research for which specialized staff or special equipment or laboratories are essential is done at the regional laboratories; the research which can be carried out at the State experiment stations is still done there; but it is now closely correlated with the work at the regional laboratories, and duplication of work between any of the co-operating States is avoided.

These laboratories are, of course, quite distinct from the other experiment stations and laboratories which have been located on a regional or "problem area" basis, such as the soil and water conservation experiment stations and hydraulic laboratories of the Soil Conservation Service, or the forest and range experiment stations of the Forest Service.

The regional laboratories concerned with research on crop plants and products are three in number; four deal with animal problems, and two with soil-plant relationships.

The U.S. Regional Vegetable Breeding Laboratory (Director: Dr. B. L. Wade) is at Charleston, South Carolina, and was established to obtain the fundamental information necessary for the breeding and development of improved types and varieties of vegetable crops specifically adapted to the south-eastern region; thirteen States are co-operating with this laboratory.

The Pasture Research Laboratory has been established at State College, Pennsylvania, to carry out research on the more fundamental pasture problems of the north-eastern States, the twelve co-operating States continuing to make experiments on the more agronomical aspects. A description of the organization of this Laboratory and of the way in which it co-operates with the States concerned has already been given by its director, Dr. R. J. Garber (*Herb. Rev.*, 6, 146–50; 1938).

The twelve States of the North Central Region are co-operating with the U.S. Regional Soybean Industrial Products Laboratory which has been established at Urbana, Illinois (Director: Dr. R. T. Milner), (1) to develop industrial uses for the soybean and soybean products, (2) to study the effects of different processes on the quantity and quality of products obtained from the soybean, and (3) to provide facilities for testing the quality and adaptability of types and varieties of soybeans for industrial uses.

The four animal laboratories deal with sheep, swine, poultry and animal diseases.

The purpose of the Western Sheep Breeding Laboratory, Dubois, Idaho (Director: Mr. J. E. Nordby), is the development of strains of sheep superior to those now in existence as regards hardiness, and yield and quality of wool and lambs, and the co-ordination of this research with that of the co-operating States (twelve) and Federal experiment stations.

The U.S. Regional Swine Breeding Laboratory has been established at Ames, Iowa (Director: Dr. W. A. Craft), to study the improvement of swine by the application of breeding methods (thirteen States in the North Central Region co-operating).

The object of the Regional Poultry Laboratory, East Lansing, Michigan (Director: Mr. Berley Winton), with which twenty-five States in the North Central and North-eastern Regions are co-operating, is to determine the etiologic agent or agents responsible for fowl paralysis, to develop procedures based upon genetics, management and nutrition, and to discover prophylactic measures for the prevention or control of this disease.

Related to this last laboratory is the work of the Regional Laboratory for Animal Disease Research, at Auburn, Alabama (Director: Mr. B. T. Simms). This Laboratory was established to obtain, with the co-operation of the thirteen States of the South-eastern Region, fundamental information of the mechanism of infection (infection, resistance, immunity) in the contagious, infectious and parasitic diseases of animals and poultry, in order that methods of control of these diseases can be developed or improved. The Laboratory is studying Johne's disease and coccidiosis and internal parasites of cattle.

A Regional Salinity Laboratory, at Riverside, California, has as its objective the obtaining of new information on the reactions of plants and the soil to known concentrations of the several constituents of the dissolved salts contained in supplies of irrigation water and in the soil solutions of irrigated lands. The Laboratory will also ascertain the hydrological and salinity conditions, and the trend of these conditions in representative areas of irrigated lands, in order that the results of these investigations may be constructively applied. Eleven States in the Western Region to which these problems apply are co-operating with this laboratory.

Finally, there has been established at Ithaca, New York, the U.S. Regional Plant Soil and Nutrition Laboratory (Director: Dr. L. A. Maynard), which has very extended terms of reference and the possibility of results which will ultimately have a direct application to the nutrition of domestic animals and the human population throughout the United States.

This laboratory has the following objectives:

(1) To investigate the possibility of influencing the type, character, composition and health of plants grown under controlled environments and in the field through the application of common, rare, or trace elements, irrigation water, sprays, or other means.

(2) To investigate under such conditions the range of variability in the amount of crop produced, the structure of the plant tissue, its mineral, organic and fibre content, and the influence of various environments and environmental factors upon vitamins, growth-promoting substances and other dietary supplemental factors.

(3) To test objectively all these values by feeding the plant produced to the usual laboratory test animals and making observations on rate of development, behaviour, condition, and eventually dietary and nutritional studies.

(4) To determine the dietary needs and tolerance of man and domestic animals for several of the known essential or toxic elements.

(5) To classify geographical regions in the United

States with respect to the adequacy of supplies of different mineral elements through correlated studies of the composition of soils, crops and animals.

(6) To determine methods of adjusting the mineral composition of plants used for animal or human food in various areas of the United States, by the addition of fertilizers carrying the desired elements or by spraying or dusting the plants, or by other means.

(7) To study the efficacy of supplementing mineral-deficient diets of man or animals by the direct addition of minerals and growth substances to the ration.

As the work of this laboratory has a nation-wide significance and application, co-operation will be arranged with those State experiment stations, bureaux of the Department of Agriculture, and other research agencies which already have special facilities and staff members especially interested in one or other of the many aspects of this research.

SCIENCE AND ART AT THE ROYAL ACADEMY

By Dr. A. T. Hopwood

British Museum (Natural History)

THE canons of art differ greatly in detail from those of science, but since intellectual honesty is the basis of both, there is no fundamental distinction between them. To make an orderly statement of accurately observed facts and from those facts to draw logical conclusions is the very essence of science ; but the best art is also logical and orderly, as well as being an accurate interpretation of the impression made by the outside world upon the mind of the artist. Observe the words "interpretation" and "impression" ; they are important because they lie at the very root of the matter ; whereas science is, or should be, strictly objective, art is intensely subjective. For the rest, the differences are mainly those of design, technique, and of the medium of expression. Is it always recognized that there is as much skill in design shown by the well-written and well-balanced scientific paper as there is in a first-class painting, and that when J. M. W. Turner removed a castle bodily from one bank of the river to the other, because in this way he improved the design on his canvas, he was doing no more and no less than the man of science who puts one section of his paper in front of another so as to improve the balance of the whole ? In so far as the man of science recognizes these differences and leaves his prejudices, which are many, outside, so his bewilderment will decrease and his interest and enjoyment increase. In this year's Exhibition at the Royal Academy much is provided to enjoy, and very little to bewilder.

The botanist is always well catered for ; this time he is more fortunate than usual. Apart from the landscapes there is a very large number of flower pieces, which range from W. Rankin's big pictures in the Dutch style, highly finished and accurately drawn, to sketchy impressions incapable of recognition without recourse to the catalogue. "The Change", by Heda Armour, is presumably allegorical and so should be immune from the scientific Philistine, who contents himself with wondering when winter aconite, snowdrops, flag irises and the cuckoo all came together in the same place at the same time. The botanist, too, is this year favoured by the only obvious jest, "The Champion", by J. W. Tucker. This is a monstrous cauliflower to the grower of which homage is being paid by the mayor and corporation with the press and news-reel men in attendance. Mr. Tucker has chosen tempera as his medium and achieved his end, but painting in tempera as practised at the present day does not seem to be suitable for the successful interpretation of flowers, fruit and vegetables. Be the subject what it may, vegetable marrows, carrots, apples, or even the trunks of beech trees, the impression is always of carefully finished plaster models. Incidentally, there is no well-painted fruit this year because of the shortage ; memories have played their owners false and the result is lacking in juice and texture.

Pictures for the zoologist are not many. Two of them, "The Jungle", by Shearer Armstrong, and "The Pine Marten", by Billie Waters, are purely zoological, although the monkeys in the first-named have been somewhat stylized so that one is left uncertain as to what species are intended. For the rest, there are a few shells, particularly good in Mr. Dinkel's "Flower Piece with Shells", some scrawny cats incidental to other subjects, at least one impossible fish, and various kinds of domestic animals of greater or less merit. Among the water-colours, "Flowing Tide" and "Lapwings in Spring", both by C. F. Tunnicliffe, attract attention, but it is in the Sculpture Rooms that zoological subjects are mainly to be found. The best of these are more or less conventional, as, for example, "Yearling", by Raoh Schorr—a bronze statuette of a fawn somewhat after the style of

Skeeping—and "Lamb" by H. Wilson Parker. The horses are not good; one, at least, has the shoulder muscles at fault, and another drags its off hind leg in a painful manner. Neither of the tortoises is particularly successful. The other pieces are competent rather than inspired.

Geologists and mineralogists have very little to claim as their own particular interest, but they share the magnificent painting of the jewellery in Gerald Kelly's charming portrait of Her Majesty the Queen. Precious stones are notoriously difficult to paint; Mr. Kelly has triumphed with a marked economy of pigment and a brilliant sureness of touch.

The mathematician will interest himself mainly in the laws of perspective and their application, and even though there is no solution in paint of a complicated mathematical problem to compare with Mantegna's famous "Dead Christ" or the pulsating rhythm of Uccello's "Rout of San Romano" for him to admire, he would be well advised to examine carefully "Sir Charles Grant Robertson, C.V.O.", by Meredith Frampton, A.R.A., and "Coupons Required", by Leonora K. Green.

As regards physics and chemistry, what is there which concerns them? In a sense the whole exhibition is their oyster. The chemist has a father's interest in the pigments, in their behaviour in mixture, as well as in their use or misuse, while problems of light and shade are for the physicist, who may perhaps one day see a "Portrait of a Sound", even as there has already been a "Photograph of a Smell" (Royal Photographic Society Exhibition, 1938).

Taken as a whole, the exhibits in the South Rooms are not so good as in former years, but there is a very interesting sheet of pencil studies of old agricultural implements—"Details from a Devon Farm", by Russell Flint, R.A. Not only are the drawings pleasing but they are also of historical interest, for they represent a dying phase of agriculture.

At least one man of science always takes a deep breath before venturing into the Architectural Room, for he finds the angularity of "Modern" designs uncomfortable and their curves repellent or even obscene. This year he sighed with relief to find that our English genius has once more triumphed over the upstart invader and that the native tradition still flourishes.

Many words and very little sense have been spent in discussions on modern architecture. Some of its features are admirable; such, for example, are the elimination of waste space and the planning of the fire-places so that the flues run up inside the building instead of dissipating their heat through outside walls. White houses in England there always have been, and coloured roofs as well; the change is in the substitution of more permanent materials for whitewash and in the addition of deep blue and green glazed tiles to the traditional unglazed red.

One's quarrel is with none of these things, but with the perverse body which insists on being revolutionary. The fact that steel and concrete can be made to assume certain forms does not mean that it is desirable that it should be made to assume those forms. That light and fresh air are essential to health is no excuse for designing windows so large that the illuminated rooms are impossible to keep warm during cold weather. As for severity of line and beauty of well-proportioned masses, a boot-box can be severe and well proportioned, but what is suitable for a boot-box is not necessarily suitable for a dwelling-house. There are three parties interested in houses: the housewife, who requires ease of working, the householder, who requires comfort as well as value for money paid, and the community, which has the right to demand that a building shall consort amicably with its surroundings. Unless the architect can satisfy all three he has failed. It is much to their credit that the architectural exhibits in the Academy this year make an honest attempt to fulfil these conditions; and even if there are still such curiosities as windows in which the length of the pane is horizontal instead of upright, the vulgarity of the extreme modern school—vulgar just because it is extreme—is nowhere to be seen.

OBITUARIES

Dr. G. W. C. Kaye, O.B.E., F.R.S.

DR. GEORGE WILLIAM CLARKSON KAYE, superintendent of the Physics Department, National Physical Laboratory, passed away on April 16 after a long illness. His name became familiar to students of science thirty years ago as the co-author of "Tables of Physical and Chemical Constants", which have now reached their eighth edition. He was born in 1880 and studied physics at the Imperial College of Science, then the Royal College of Science, and later at Trinity College, Cambridge. For Cambridge he retained a warm affection throughout his life, and he was at his best when showing a friend round the colleges and the Cavendish Laboratory. For a time he assisted Sir J. J. Thomson in his research work.

Kaye joined the staff of the National Physical Laboratory in 1910, and at first worked in the Metrology Department on the production of a silica standard of length. In 1912 he was transferred to the Physics Department to take charge of the thermometer testing work, then taken over from Kew Observatory, and of radium measurements.

As a captain in the London Electrical Engineers R.E.(T.), he was called to the colours in August 1914 and for a time served at a Thames Estuary Station on searchlight work. Later he transferred to the Aeronautical Inspection Directorate of the Air Ministry, in which organization he rose ultimately to the position of chief inspector of materials, with the rank of major. It was in this position that he applied X-rays to the examination of various types of timber splices. The A.I.D. gave him much experience in the handling of men of many types and of committee work, which appealed especially to him. On his return to the National Physical Laboratory, he took charge of the Physics Department and was appointed superintendent in 1922. He was primarily interested in the administrative side of the work and for more than twenty years he was chairman of the Library Committee of the Laboratory.

Kaye was especially interested in the British X-ray and Radium Protection Committee, and took an active part in the deliberations of the International X-Ray and Radium Protection Commission of the various Congresses of Radiology. He gave the eighth Caldwell Memorial Lecture before the American Roentgen Ray Society in Montreal in 1927, and his presidential address to the British Institute of Radiology in 1929 was entitled "Radiology, Medieval and Modern". At one time thermal measurements attracted his attention, and a number of papers were published jointly with various colleagues.

It was not, however, until the need arose for the inclusion of the subject of sound in the activities of the National Physical Laboratory that Kaye found scope for his special talents. He took great pride in the design of the new Acoustics Laboratory, and neither time nor money was spared to ensure that Great Britain should be in the forefront as regards equipment for the study of the acoustics of buildings and allied problems. Special attention was devoted to noise measurements, on which subject a number of papers was published. These constituted the basis of his presidential address to Section A of the British Association at the Nottingham meeting in 1937. His election to the presidency of Section A afforded him the deepest satisfaction, and much time was spent in the preparation of his address, which was lavishly illustrated by experiments and with a cinematograph film.

Soon after Kaye became superintendent of the Physical Department of the National Physical Laboratory, it had become apparent that a rehousing of the Department was necessary. He undertook wholeheartedly the task of specifying the requirements of the Department and, in conjunction with the then Office of Works, in preparing the basic plans of the present structure. Many times the schemes were turned down for reasons of economy. This delay did not prevent Kaye from keeping the plans abreast of modern requirements, and features of the building have since been incorporated in other new laboratories built in Great Britain.

Kaye was the recipient of many honours, which included the Mackenzie Davidson Medal of the Royal Society of Medicine and the Silvanus Thompson Medal of the British Institute of Radiology. He was elected a fellow of the Royal Society in 1939.

Ezer Griffiths.

Prof. Charles Laubry

By the death of Prof. Charles Laubry of Paris at the age of sixty-eight, the announcement of which rapidly follows that of Prof. Wenckebach's (see Nature, March 1, 1941, p. 260), though the exact date is unascertainable in present circumstances, medical science has lost another pioneer in modern cardiology, and particularly in the application of radiology to diseases of the heart.

Laubry was a pupil of the late Prof. Vaquez of Paris, whose school exercised a great influence over current cardiological teaching throughout Europe and Latin America, though less in Great Britain and the United States. His literary output was considerable. His principal works in chronological order were: "Leçons de sémiologie cardiovasculaire. Les troubles fonctionnels" (1924), "Traité des maladies congénitales du cœur" in collaboration with Pezzi of Milan (1926), and "Radiologie clinique du cœur et des grands vaisseaux" in collaboration with Cottenot, Routier and Heim de Balsac (1939). He was also editor of the *Archives des maladies du cœur.*

In addition to his cardiological work, he was the author of the section on the symptomatology of diseases of the respiratory system in the third volume of the "Nouveau Traité de Pathologie Interne" (1938).

Like Prof. Wenkebach, Laubry had many friends in Great Britain. He delivered the Saint Cyres Lecture at the National Heart Hospital in 1937, and he was an honorary member of the Cardiac Society. He was elected an honorary foreign fellow of the Royal Society of Medicine in 1939.

We regret to announce the following deaths:

Mr. N. C. Brown, known for his work on the distribution and habits of North American birds, on March 20, aged eighty-four.

Sir James Frazer, O.M., F.R.S., the well-known anthropologist and author of the "Golden Bough", and Lady Frazer, on May 7, aged eighty-seven.

Prof. G. L. Gulland, C.M.G., emeritus professor of medicine in the University of Edinburgh, on May 4.

Prof. L. Kahlenberg, formerly professor of chemistry in the University of Wisconsin, on March 19, aged seventy-one.

Prof. Nikolaj Konstantinovic Koltzoff, director of the Moscow Institute of Experimental Biology, aged sixty-nine; in making this announcement in Nature of April 19, p. 474, Prof. Koltzoff's surname was omitted.

Prof. A. C. Pereira, professor of toxicology in the University of Lisbon, on December 20, aged seventy-three.

NEWS AND VIEWS

Terrorism in Aerial Attack

THOSE of us who experienced the heavy attack on London by the German Air Force on Saturday night (May 10–11) were once more convinced of its deliberately indiscriminate nature with the obvious aim of striking terror into the hearts of Londoners—an aim as ineffectual as it was barbaric. Never has there been a raid in which so much damage was done, in brilliant moonlight, to buildings of architectural and cultural value—Westminster Abbey, Dean's Yard, Westminster Hall, the Houses of Parliament, the British Museum, etc. On the other hand, we venture to say, never was there a raid in which so little damage was done to objectives of military importance. One of the editors of NATURE had occasion to go from Westminster through a heavily raided area while the attack was at its height; and once again he was firmly convinced of the absolute futility of this form of attack—futile from the point of view of the Nazis' own war strategy. For the enemy did nothing to further his own aims, though he did much against them in rousing the ire of the British and, afterwards, the contempt of every balanced thinker throughout the world.

The *Völkischer Beobachter* stated that "British broadcasting reports that London is one single sea of flames—the Luftwaffe's heaviest retaliation attack on the British metropolis". Retaliation, in modern warfare, is useless; it is merely an expression of hysteria. The same newspaper asserted that "Naturally the British again assert that our mass attack was indiscriminate, but the High Command reports objectively that the region round the bend of the Thames—that is, the centre of London's docks and business quarters, was again the focus of attack". The considerable area through which one of the editors passed was being deliberately attacked and continued to be the objective of incendiaries and high explosives for several hours. That area is miles from the London docks. Furthermore, nowhere did he see signs of terror, but heroic battling with the fires and grim though calm working on ruined buildings while bombs continued to rain down. No amount of this kind of brutal bombing of buildings which are a nation's—even a world's—heritage and of helpless civilians can bring such a people to its knees. Neither can it help the enemy one jot; rather does it condemn him as unworthy of the wonderful heritage that should be his in his own country, unworthy of all that art and science are able to place at his disposal. Other cities—Plymouth, Bristol, Liverpool, Glasgow, Manchester, Birmingham and many others—will assuredly voice the same opinion.

New Type of Airscrew

INFORMATION has just been released of the successful use of a new type of airscrew on British aircraft, principally those of the Fleet Air Arm operating from the deck of an aircraft carrier. It consists of two co-axial airscrews, one directly behind the other, rotating in opposite directions, each having controllable pitch blades. The development of this device, known as a 'Contraprop', is due to the necessity for turning into thrust the rapidly increasing horse-power being given by the latest aero-engines. Up to 2,000 h.p. is now given by engines coming into service, which on certain types of fighters gives speeds of more than four hundred miles per hour.

The principal trouble in absorbing such powers has been the increase of diameter of the airscrew. The limit, both aerodynamical and practical, is now about reached, in the increase of diameter and multiplication of blades. The placing of one propeller behind the other defeats both of these troubles and simplifies the problem of undercarriage design, especially of the tricycle type, by allowing the machine to be lower, as the smaller diameter needs less ground clearance. Airscrew torque, which causes a machine to tend to swing to one side when taking off, is cancelled out by the opposing directions of rotation. This is important in the case of machines taking off from a confined space such as an aircraft carrier's deck. The absence of torque also increases the rapidity of certain manœuvres in the air. A special control, combined with the adjustable pitch mechanism, enables either propeller to be kept working if the other is damaged, which in effect increases the reliability of the power unit as a whole. For fighting purposes it is made so that cannon can fire through the centre of the hub if required. It is claimed that the device can be produced at no greater weight than a single propeller capable of absorbing equivalent power.

The Transport Problem in Great Britain

THE appointment of Mr. F. J. Leathers to the new post of Minister of War-time Communications, thus combining the duties of Minister of Transport and Minister of Shipping, is to some extent an answer to criticisms of the transport systems of Great Britain made in the eighth and tenth reports of the Select Committee on National Expenditure. Both reports are highly critical of the lack of foresight which has allowed the present shortage of coal supplies and stocks and the difficulties in handling shipping at the docks to develop. Even under war conditions, the Sub-Committee on Transport Services considers that a ship can be unloaded and loaded again more quickly than transport can take traffic from, or bring traffic to, the ports. The failure to secure the existence of equipment such as powerful cranes and elevators which could be transported to and erected at the ports where need arose is strongly condemned. The Sub-Committee recommends the acceleration of delivery or transfer of such mechanical equipment and also that there should be no cessation of work in ports during 'alerts' unless danger is imminent. While the appointment of regional port directors by the Minister of Transport has been welcomed, the Sub-Committee points out that time alone will show whether such appointments, in some cases of men without previous experience of all the ramification of shipping and port management, is likely to bring success in discharging adequately and efficiently the very onerous responsibilities involved in securing the rapid clearance of both ports and ships.

Other recommendations in the tenth report include the acceleration of manufacture of railway wagons of special type ; closer co-operation at overseas ports between the Ministries of Shipping and Transport so that cargoes may be more suitably arranged with a view to their ultimate destinations ; transfer of suitable engineers from industry to the merchant service and employment of an experienced shipbuilding engineer to visit repairing yards and suggest improvements in mechanical equipment. More ship repairs should, where possible, be effected abroad and among all practicable steps to overcome transport difficulties, the Sub-Committee reiterates its recommendation in the eighth report that particular attention should be directed to the possibility of curtailing or withdrawing passenger trains on specified days to permit more freight trains to be moved.

While the Sub-Committee considers that it is impracticable in war-time to contemplate a scheme submitted to them for concentrating railway traffic at stations 20 or 30 miles apart for exchange with road vehicles, and closing intermediate stations, such a scheme might repay further consideration after the War. In the meantime the Sub-Committee is awaiting the results of an investigation of the possibility of greater use being made of the canal system and also of proposals for using road transport in greater volume to assist the railways in clearing docks and other centres. It severely criticizes the failure of Government departments to consult the Mines Department when extensions or new factories are planned, and recommends that such Departments should be required to provide the Mines Department with quarterly estimates in advance in areas where supplies are short and future needs will expand. It also recommends that a more comprehensive scheme be planned at once to create coal stocks to meet next winter's demands, and that closer co-operation should be organized between coal merchants to pool requirements of stocks of household coal, labour and local transport.

British Standards Institution

SOME months before the outbreak of war, the British Standards Institution offered the Government its services, as a complete unit, in the national emergency. This offer, which was sent to the Board of Trade, through which the Institution receives its Government grant, was cordially received. On the outbreak of war, the Institution set up a number of small executive committees for the various sections of its work, these being made fully responsible for the preparation of any war emergency specifications required. A statement has now been issued outlining the Institution's recent activities. The Institution has been invited to send a representative to appropriate meetings of the Materials Committee of the Production Executive, which is representative of all Government departments, the Central Priority Department acting as the liaison between that Committee and the Institution. The first issue of the War Emergency Specifications for Tins and Cans for food products and other commodities is estimated to have saved 40,000 tons of steel in the first year, while it is estimated that the War Emergency Specification for Bolts and Nuts with smaller heads will save many thousands of tons of steel a year.

Another example of the work of the Institution concerns alloy and special steels. A committee under the chairmanship of Dr. W. H. Hatfield, has for some time past been engaged on an investigation of this complex problem and has drawn up a confidential report which includes suggestions for a co-ordinated series of steels. Such sections of the report as can be made available to the engineering public are being issued by the Institution, which at the same time is issuing War Emergency British Standards covering the steels recommended in the report. The Ministry of Works and Buildings is using the Institution for the promulgation, under its authority, of a series of War Emergency British Standards, and about fifty specifications in connexion with A.R.P. work have been issued at the request of the Ministry of Home Security.

Such work of immediate importance has not prevented the British Standards Institution from maintaining its close relationship with the Dominions' standardizing bodies. In addition, the Institution's Committee in the Argentine Republic, which is working in close collaboration with the Argentine national standards organization, is receiving increased recognition, as its work is seen to be of real value to British export trade. British engineers and traders in the Argentine are to a greater degree giving practical support to the work of the Committee. The Institution, with the help of the British Council and of industry, is also engaged in compiling a number of technical handbooks dealing with British industrial practice. The books are to be published in Spanish and Turkish.

Gypsy-Lore

EVER since the time of Borrow the mystery of the gypsy-folk has intrigued those of us who have seen, and still occasionally see, their caravans encamped in some lovely dell ; and Borrow would have been the first to welcome the serious study which since his day has been devoted to these people so that now we know much more about them than he could. The mystery, however, still remains. The current number of the *Journal of the Gypsy-Lore Society* makes interesting reading, its subject-matter ranging from the sixteenth century in Transylvania to modern times in Spain. Especially dramatic, if of no great scientific importance, is the account of an unusual friendship struck up between an Englishman and a gypsy youth as the result of help given in a brawl in a Montparnasse estaminet. The two eventually travelled together to visit the gypsy's parents in Madrid—shortly before the lad himself was killed in an accident.

The gypsy language naturally becomes modified by the speech of the people among whom the wanderers have penetrated. Thus Bosnian Romani shows signs of the influence of the Slavonic language with which it is most closely associated, and in this connexion a preliminary study of Bosnian Romani and of certain North Albanian texts will doubtless be of interest to language students. One cannot help wondering what these alien wanderers who still survive among so many of the warring European nations can be thinking, if they think so widely, of the present suicidal struggle of their hosts.

Place-Names in the United States

THAT the study of place-names, apart from its intrinsic interest, is an invaluable source of illuminating evidence for archæologist, anthropologist and social historian, has become a commonplace among all who are familiar with the publications of the English Place-Name Society. Analogous studies of place-names of Indian origin have been made in the United States; but there the untrustworthy character of early documents, if not their complete absence, is a difficulty which is only partially overcome by reference to those few survivors who are still acquainted with the original Indian language. Dr. J. P. Harrington, of the Smithsonian Institution, arrives at the meaning of names of Indian origin in the eastern United States by reference to Delawares now resident in eastern Oklahoma, whose language is one of the few eastern languages still surviving, predominantly the tongue of the Pennsylvanian Indians at the time of first settlement. It is interesting to note that many place-name elements were immediately recognized by living Delawares, but others remained doubtful, even when the words were reconstructed by them out of the basic elements of their language. Of the names submitted for interpretation, "Chesapeke", for long a puzzle to students, is said to be "salt bay" from *chesa* = salt and *peekw* = body of water. Susquehanna is "muddy river", and Monongahela, "caving banks". Potomac, which previously had been interpreted as "carrying place" or "centre for trading", is now construed in the opposite sense as a place where a man lays down a burden, resting place—presumably the place at which Indian war or trading parties took a rest when they came in sight of some village approximately in the present position of the city of Washington.

Indian Fisheries

A report on a survey of the fisheries of Bengal by Dr. R. Naidu (Bengal Govt. Press, 1939) which has only recently been received, contains valuable information on the present state of the Indian fisheries. There is a descriptive account of the fishing methods, followed by details of the commercially exploited groups of fishes in the different parts of Bengal and of the recent work done in other provinces to improve the fisheries. The hilsa or the Indian shad (*Hilsa ilisha*) is the most popular food fish of Bengal; the report makes it clear that unless hatcheries are provided and protective legislation enacted, this valuable fishery will rapidly be depleted at the present rate of fishing. The condition of the carp fisheries, which come next in importance, is equally unsatisfactory, for, though carp culture is widely practised in Bengal, the methods in vogue are wasteful and destructive. The dried fish and prawn industries are considerably developed in the province, but the methods of preparation of the products for the market leave much to be desired. Analysis of the fishing trade points to the deplorable economic condition of the fishing populations who form the backbone of the industry; though fish are plentiful and prices high, a disproportionately high percentage of the profits go to the middlemen who intervene between the fishermen and the consumers. The recommendations made include the organization of a new department with properly equipped stations and personnel, and if given effect to, should substantially improve the fishing industry of the province. Bengal had a separate fisheries department for some time, but it was abolished in 1923. From the facts presented in the report it is difficult to understand how the fisheries of the province could be improved without a properly organized fishery administration.

It is impossible to exaggerate the necessity for developing the fisheries in a country like India where a high percentage of the population is undernourished; the supply of good fish throughout the country by efficient methods of storage and transport would not only raise the nutritional standards of the people but would form also the basis of an industry which has great scope for expansion. We understand that quick-freezing refrigeration plants have already been installed in some parts of India. There is, unfortunately, no organized plan of development of the fisheries of the country as a whole; while some provinces like Madras are ahead of the others, most provinces have no fishery departments at all. The attitude of the provincial Governments seems to be that the departments should mainly rely on their own income for expansion; this short-sighted policy has very much limited the activities of the existing departments. Much work remains to be done to elucidate the habits and life-histories of Indian food fishes. Recent work on some of them has been noticed in NATURE (146, 657; 1940). The problem is too vast to be tackled by the fisheries departments alone. We venture to suggest that they should enlist the co-operation of Indian universities and other institutes which have provision for post-graduate research, by providing grants-in-aid for investigating specified problems. In any case a central body to co-ordinate the work done at the different centres would be essential.

Private Estates and Forestry

A paper on this subject was read by Major C. P. Ackers before the Royal Society of Arts on February 26, 1941. Some introductory remarks on the history of forestry in Great Britain were made and forestry education was alluded to. It is incorrect to say that forestry education seriously started at Oxford under the late Sir William Somerville. The late Sir William Schlich took forestry to Oxford when the R.I.E. College, Coopers Hill, was closed in 1905. Somerville was the first lecturer in forestry at the University of Edinburgh; afterwards his connexion was with agriculture. Major Ackers correctly states that the position of British woodlands of all types and ownership had sunk to a very low management before the War of 1914–18 and with the exception of the afforestation work of the Forestry Commission and a few isolated private instances the management has scarcely improved since.

Some of the author's ideas for improvement of forestry in Great Britain will not receive general endorsement. Sylviculturally the suggestion that whenever the prospects are reasonably in favour, mixed crops of conifers and hardwoods should be grown, is sound. Such mixtures are admittedly more difficult to manage than pure crops or mixed crops of conifers. But it is true to say that in many parts of England and certain parts of Scotland and Wales they would fulfil soil requirements and the local country-side markets, besides re-introducing small local industries. Although it must remain true that Great Britain could never grow enough wood, etc., to supply the requirements of its population, yet with equal truth it may be asseverated that a long-term policy is essential. Such an indispensable condition has so far never been conceded by either Government or private owner.

Swine Influenza in Britain

In a paper on this subject read before the Section of Comparative Medicine of the Royal Society of Medicine on April 23, Mr. F. Blakemore said that swine influenza has been extensively studied in America and a somewhat similar disease named *Ferkelgrippe* has been described in Germany and most European countries, including Northern Ireland. It has not been recorded in Great Britain, but many clinicians maintain that a specific pneumonia causes considerable loss, so that it is important to study the etiology of the disease and ascertain its relationship to conditions investigated elsewhere. An outbreak of influenza affecting pigs 10–14 weeks old in which the symptoms were typical of those described by Shope in America was investigated. In severe cases there was a lobular pneumonia affecting principally the anterior lobes. The mortality was low but recovery was slow.

Hæmophilus influenzæ was recorded from half the pigs examined, and the presence of a virus was demonstrated by the intranasal instillation of a filtrate of pneumonic lung. The virus was afterwards established in ferrets, and neutralizing antibodies were demonstrated in the blood of convalescent pigs to the ferret-adapted virus. An investigation of a further four selected outbreaks of pneumonia in pigs revealed the presence of a virus and in two of these the agent was adapted to the ferret. *Hæmophilus influenzæ* was obtained from only a few of the pigs; other infecting bacteria were *Pasteurella suiseptica*, *Br. bronchiseptica*, Salmonella, streptococci and unidentified Gram-positive bacilli. An attempt was made to ascertain the incidence of influenzal pneumonia by examining the lungs of pigs at a public slaughterhouse. Lesions of the kind found in outbreaks previously studied were observed in a proportion of cases. *Hæmophilus influenzæ* was recovered from three of forty affected lungs obtained from the slaughterhouse. Transmission experiments with material from two lungs were carried out. The disease was readily reproduced in pigs, and one of the strains was later adapted to the ferret.

Effect of Low Temperatures on Aircraft Metals

Temperatures as low as −60° C. may be reached by parts of the structures of aircraft flying at great heights. S. J. Rosenberg (*J. Res.*, *Nat. Bur. Stand.*, 25, 673; 1940) has examined the effect of low temperatures, down to −78° C., upon the tensile properties, hardness, and impact resistance of metals commonly used in building aircraft. For the materials tested, including ferritic steels, austenitic stainless steels and nickel alloys and light metal alloys (Al- and Mg-base), none of these mechanical properties was adversely affected by low temperatures with the exception of a decrease in impact resistance of ferritic steels as the temperature fell. In common with all papers published in this journal, the present paper may be bought as a separate reprint (Research Paper R.P. 1347), from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C.

Dr. James Hope

Dr. James Hope, one of the most eminent London physicians of the first half of the nineteenth century and one who contributed much to our knowledge of diseases of the heart, was born at Stockport, Cheshire, on February 23, 1801, the tenth of a family of twelve. He studied medicine at Edinburgh, where he qualified in 1825 with a thesis on aneurysm of the aorta. After spending two years in foreign travel including a year in Paris under Chomel, he settled in London in 1828 and soon acquired an extensive practice. He made numerous contributions to periodic literature on heart disease, and in 1831 published his chief work entitled "A Treatise on Diseases of the Heart and Great Vessels", which comprised a new view of the physiology of the heart's action according to which the physical signs are explained. In the following year he was elected a fellow of the Royal Society. In 1834 he was elected assistant physician and in 1839 full physician to St. George's Hospital. His second most important work was published in 1833 and 1834, entitled "Principles and Illustrations of Morbid Anatomy adapted to the Elements of

M. Andral and to the Cyclopædia of Practical Medicine, being a complete series of coloured lithographic drawings from originals by the author". He died on May 12, 1841, at the early age of forty.

Spectrochemical Literature

THE second volume of *Spectrochemical Abstracts*, covering the years 1938–39 and edited by E. H. S. van Someren, has just been issued by Messrs. A. Hilger, 98 St. Pancras Way, N.W.1. More than 150 papers and books are listed under authors' names, and the classification of substances analysed and elements determined is very thorough. The pamphlet is a valuable summary of material scattered in many journals.

Books and papers of metallurgical interest are similarly covered by the *Bibliography of Spectrochemical Analysis* compiled by D. M. Smith and published by the British Non-Ferrous Metals Research Association, Euston Street, N.W.1. The second edition, costing three shillings, has been brought up to date, to August 1940, and now includes more than five hundred entries. A new section on Application of the Microphotometer lists twenty-one researches. Short explanatory notes are given with most of the references and an author index is provided.

Earthquake in Manchuria

AN earthquake of considerable intensity is reported to have taken place early on May 6 in northern Manchuria. Insufficient reports have so far been received to fix the epicentre with any precision but it must have been fairly close to Suihwa, forty miles north-east of Harbin, where thirty-three were killed and several injured. It is also reported that scores were killed and injured in other nearby cities. It will be recalled that one of the larger earthquakes of 1940 took place in Manchuria on July 10.

Institution of Electrical Engineers: Awards

THE Council of the Institution of Electrical Engineers has made the following award of premiums for papers read during the session 1940–41, or accepted for publication: *Institution Premium:* Mr. C. F. Booth; *Ayrton Premium:* Mr. W. A. Cook; *Fahie Premium:* Messrs. A. Fairweather and J. Ingham; *John Hopkinson Premium:* Mr. G. H. Rawcliffe; *Kelvin Premium:* Messrs. C. E. R. Bruce and R. H. Golde; *Extra Premiums:* Mr. C. G. Garton, Messrs. L. Gosland and W. F. M. Dunne, Prof. Willis Jackson and Mr. A. E. Chester, Dr. R. Jessel, Messrs. W. J. Mason and S. A. G. Emms, Mr. G. H. Metson, Mr. A. Langley Morris; *Wireless Section Premiums:* Messrs. N. M. Rust, O. E. Keall, J. F. Ramsay and Dr. K. R. Sturley (Ambrose Fleming Premium), Messrs. C. A. Mason and J. Moir, Dr. R. H. Barfield; *Meter and Instrument Section Premiums:* Dr. A. E. W. Austen and Dr. S. Whitehead, Mr. A. J. King, Dr. R. W. Guelke, Mr. C. R. Maguire and Dr. R. A. Scott; *Transmission Section Premiums:* Mr. F. R. Perry (Sebastian de Ferranti Premium), Dr. C. Dannatt and R. A. Polson.

Announcements

THE Sir John Kennedy Medal of the Engineering Institute of Canada has been presented to Lieutenant-General A. G. L. McNaughton, commander of the Canadian Corps in Great Britain and lately president of the National Research Council of Canada. General McNaughton described the present position of research in Canada before a meeting of the Royal Society of Arts on May 13; we hope to print a substantial part of this lecture in an early issue.

PROF. L. G. M. BAAS BECKING, professor of botany in the University of Leyden and director of the well-known Leyden Botanical Gardens (NATURE, 142, 1013; 1938), is now in custody in a prison at Scheveningen, Holland.

DR. THOMAS MIDGLEY, JUN., of Kinetic Chemicals, Inc., has been awarded the Priestley Medal, the highest award of the American Chemical Society, for his discovery of the anti-knock properties of tetraethyl lead, as well as other outstanding achievements in chemical science. Dr. Midgley has already been awarded the Nichols, Longstreth and Perkin Medals.

THE thirty-first annual May Lecture of the Institute of Metals will be delivered in the New Clarendon Laboratory, Oxford, by Dr. F. Simon, reader in thermodynamics in the University of Oxford, on May 28. Dr. Simon will speak on "The Significance of Low Temperature Research". Admission is by ticket, obtainable free of charge, from the Secretary, Institute of Metals, 4 Grosvenor Gardens, London, S.W.1, or the Secretary, Clarendon Laboratory, University Museum, Oxford.

THE following appointments in the Colonial Service have recently been announced: D. T. Lloyd, surveyor, Sierra Leone; E. B. Lambert (assistant superintendent of Crown lands), superintendent of Crown lands and surveys, Hong Kong; L. Lord (formerly divisional agricultural officer, Ceylon), secretary to Colonial Advisory Council of Agriculture and Animal Health and assistant to Agricultural Adviser, Colonial Office.

THE following appointments in the University of Sheffield have recently been made: Dr. S. A. Peyton, University librarian; Mr. F. J. S. Esher, assistant lecturer in mental diseases; Mr. M. Laird, junior demonstrator in anatomy; Mrs. Mildred John, part-time demonstrator in anatomy.

The Council has received from the executor of the late Mrs. E. G. Willis a cheque for £1,000 in payment of a legacy left to the University for the foundation of a scholarship in engineering or metallurgy in memory of her late husband, Mr. T. W. Willis.

The collaborators of the late Prof. R. V. Wheeler have presented to the University a complete set of his published researches, together with a glass cabinet to contain the volumes.

The Council has received the resignation of Dr. F. E. E. Schneider of his post of assistant lecturer in mental diseases, and Mr. T. C. Joyce of his post of lecturer in electrical engineering.

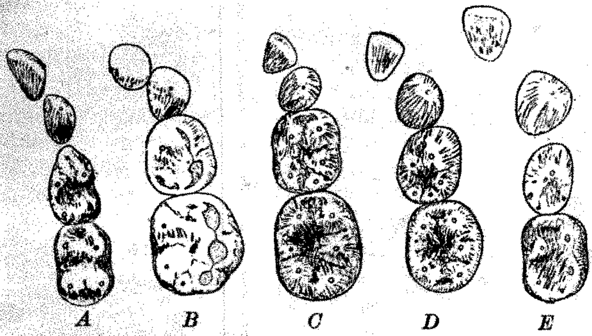
LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Mandible of a Young Paranthropus Child

ONE of the difficulties in making comparisons of the Taungs and the Sterkfontein and Kromdraai apes has been that the Taungs ape is only known by the skull of a 4–5-year-old child, while the other apes are only known by adult specimens and a fragment of the jaw of a 10-year-old Sterkfontein ape. Now fortunately we have a little further evidence.



RIGHT LOWER MILK DENTITION OF VARIOUS PRIMATES AND MAN. FIRST INCISOR HAS BEEN OMITTED AS IT IS UNKNOWN IN PARANTHROPUS AND IMPERFECT IN AUSTRALOPITHECUS.

A, Baboon (*Papio comatus*), probably female; *B*, Taungs ape (*Australopithecus africanus*), possibly male; *C*, Kromdraai ape (*Paranthropus robustus*), probably female; *D*, Kaffir child (*Homo sapiens*); *E*, chimpanzee (*Pan* sp.), probably female. All figures very slightly enlarged.

For more than a year, owing to the War and other conditions, no work has been done at Sterkfontein or Kromdraai; but three weeks ago I went out to Kromdraai and set my assistant to work at a promising spot. He was immediately successful in getting part of a lower jaw with beautifully preserved teeth of a child ape a little younger than the Taungs child. The right second incisor, the canine, and the two milk molars are almost perfectly preserved and scarcely worn. The first true molar is satisfactorily preserved, but had not yet cut the gum.

On the left side we have the first milk molar and part of the canine.

There can be little doubt that this is the jaw of a young *Paranthropus robustus*. It was found within 6 ft. of the spot where the type was discovered. The first true molar is a little smaller than in the type, and this new specimen is probably a female.

When the teeth are compared with those of the Taungs ape (Australopithecus) it is manifest that the two young forms belong to different genera. I give drawings of these teeth, with for comparison drawings of the lower milk teeth in a number of other Primates and man. If the Australopithecus teeth are compared with those of Paranthropus, it will be seen that they all differ very considerably. The Paranthropus second incisor is much smaller than in Australopithecus, and so is the canine. The first milk molar in Paranthropus, while essentially similar in structure to that of the Taungs ape, differs markedly in the shape and in the arrangement of the cusps. The second molar is longer and narrower than in the Taungs ape, and it also differs considerably in the arrangement of the cusps.

There is little doubt Paranthropus and Australopithecus belong to the same family, but they cannot be very closely allied.

If the human milk molars are compared with those of Australopithecus and of Paranthropus it will be seen that there is considerable agreement, and one might almost consider the possibility of all three types belonging to one family. There must be some close affinity.

If we compare the Australopithecine and the human teeth with those of the chimpanzee we at once see a very marked difference. In the chimpanzee the second incisor and canine are much larger than in these others, and differently arranged; while the first milk molar is so very unlike those of the other forms here shown that any affinity must be remote.

In the gorilla and the gibbon, according to figures published by Röse, the first lower milk molars have a single main cusp which is clearly the antero-external cusp of the human milk premolar. In some specimens of the gorilla tooth there appears to be also a rudiment of the antero-internal cusp. In the chimpanzee there is generally a rudiment of the antero-internal cusp close to the large main cusp. In the orang there are also the two cusps practically fused into one. A glance at the figure given of the chimpanzee tooth will show how greatly it differs from the teeth of the Australopithecines.

The second milk molar of Paranthropus has the usual five cusps seen in the corresponding human tooth. It also has a little cusp between the two main inner cusps. This little extra cusp is frequently found in man. It is a Cercopithecid character that has been retained. The Paranthropus tooth is also interesting in having a very marked anterior fovea. This is a typical human character. It is present in all the Kaffir baby skulls I have examined. It is present, but much less developed, in Australopithecus. This is also a Cercopithecid character. It is well marked in the gorilla and the orang, but rather less developed in the chimpanzee.

It is interesting to observe that the probably Lower Pleistocene Australopithecus, in the structure of its milk teeth, comes considerably nearer to man than does the much later and probably Middle Pleistocene Paranthropus; and that neither of the fossil forms has any close affinity with the living anthropoids, all of which have specialized away from the ancestral type. Paranthropus retains a few more Cercopithecid characters than does Australopithecus, or man.

Influence of Vitamin D upon the Incisor Teeth of Rachitic Rats

IT has long been known that vitamin D exerts a profound influence upon the calcification of developing teeth. The action of this vitamin in massive doses upon the persistently growing incisor of the rat has been described by Schour and Ham[1] in the normal animal and by Schour, Tweedy, Chandler and Engel[2] after parathyroidectomy. In both cases the change in the dentin consisted in essentials of a hypocalcified stripe followed by a reactive hypercalcified zone. It does not appear, however, that the reaction of the dentin has been followed in rachitic rats given curative doses of the vitamin.

Through the kindness of Dr. H. A. Shapiro of the Union Health Department, I have been able to examine the teeth of rats used for vitamin D assay. The negative controls were given for 31 days a rachitogenic diet with a Ca/P ratio of 4·8. The treated animals were on this diet the same length of time but received in addition a dose of 9·2 I.U. of vitamin D on the twenty-first day. Both sets of animals were killed and examined on the thirty-first day. The upper incisor teeth were cut in longitudinal section and the changes in the dentin were investigated.

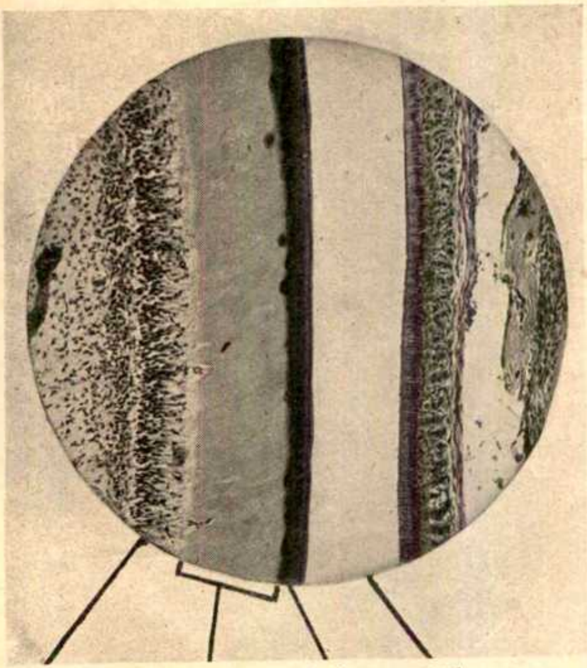

Fig. 1.

LONGITUDINAL SECTION OF THE UPPER INCISOR TOOTH OF A RAT ON THE VITAMIN-FREE DIET FOR 31 DAYS. NOTE VERY WIDE PREDENTIN. × 90. (No. 8.)

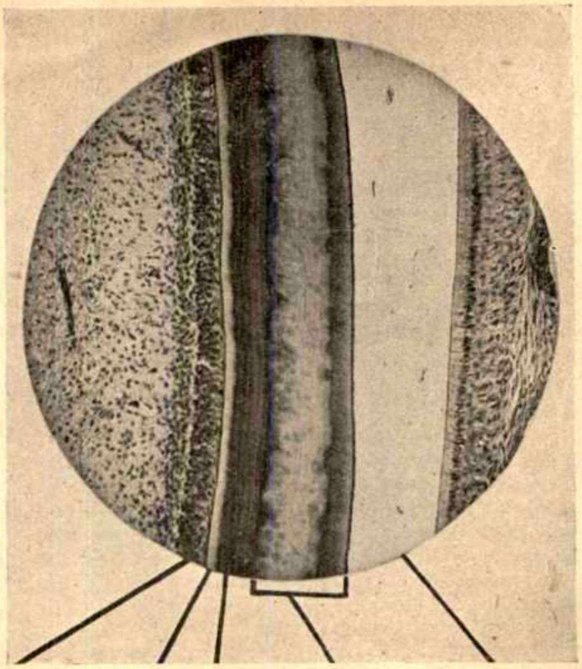

Fig. 2.

LONGITUDINAL SECTION OF THE UPPER INCISOR TOOTH OF A RAT ON THE AVITAMINOUS DIET FOR 31 DAYS AND WHICH RECEIVED 9·2 I.U. OF VITAMIN D ON THE 21ST DAY. NOTE THE DENTIN AND PREDENTIN FORMED BEFORE THE DOSE OF D WAS GIVEN AND THE REACTIVE DENTIN AND PREDENTIN FORMED UNDER THE INFLUENCE OF THE VITAMIN. × 90. (No. 4.)

The incisors of the three negative control animals studied all showed in the dentin the changes usually found in this condition—very wide predentin with vascular inclusions in several places (Fig. 1). Marked changes in the enamel and enamel organ not pertinent to the present study were also found.

The teeth of the six animals which had received the dose of vitamin D all had a markedly different appearance from that noted in the controls. The changes in these teeth were all the same in type, varying somewhat from animal to animal (Fig. 2). In each, a reactive stripe of new dentin, staining deeply with hæmatoxylin, was laid down as a result of vitamin medication. This intense calcification affected only the dentin matrix laid down after the vitamin had been given. The predentin laid down previous to this was either completely unchanged or else showed a few scattered calcified granules; and in some cases a little calcification had occurred round the vascular inclusions, giving the appearance of finger-like projections of hæmatoxylin-staining material into the old predentin. The contrast between the dentin calcified before and after giving the vitamin was very marked, as can be seen from Fig. 2. It is difficult to understand why the old predentin was not more altered, seeing that this was being calcified, though with difficulty, while the animal was on the deficient diet alone. A similar inability to calcify predentin laid down during a dietary deficiency has been noted when animals on a magnesium-deficient diet are returned to one of normal magnesium content[3].

The new dentin plus predentin differed considerably in width from animal to animal, as will be seen from the table. By dividing this width by that of the predentin laid down just before the animal was killed, an estimate could be made of the length of time vitamin D had been acting on the tooth. The figures so obtained varied from 4·2 to 6·5 days. It was assumed in this calculation that the daily increments of new dentin were equal in width to that of the new predentin. This assumption was supported by the fact that in the animal from which the figure of 6·5 was obtained, the new dentin showed six incremental stripes, which together with the predentin formed 24 hours before the animal was killed would indicate that the vitamin had acted on the tooth for seven days. These figures are on an average rather smaller than those obtained from bone by Morgareide and Manley[4], who found, using radioactive phosphorus, that rachitic metaphyses reacted 54–72 hours after dosage with vitamin D.

The depth of staining of the new dentin indicated that after ten days the D administered was still exerting a marked action.

INFLUENCE OF VITAMIN D UPON THE INCISOR TEETH OF RACHITIC RATS

Rat No.	Treatment	Width of new predentin (μ)	Width of new dentin and predentin (μ)	Days of dentin response	Degree of healing of rickets. (Line test)
1	31 days on rachitogenic diet. 9·2 I.U. of D on 21st day.	14	74	5·3	3·5
2		10	46	4·6	1·0
3		12	50	4·2	1·0
4		12	60	5·0	3·5
5		13	84	6·5	3·0
6		10	44	4·4	0
7	31 days on rachitogenic diet only.	—	—		0
8		—	—		0
9		—	—		0

Some correlation was noted between the width of new dentin plus predentin and the healing in the bones as measured by the line test (Dyer[5]). The widest reactive dentin was found in those rats that showed the highest degree of healing and the narrowest in those with little or no healing. It would thus appear that the tooth is more sensitive to the action of D than are the epiphyses and also that a time element enters into the degree of healing of bony rachitic lesions. It is possible that if rat No. 6 had lived longer, it might have shown some healing of the bones. It should be noted that the reaction of the dentin in all teeth, judged histologically, was equally intense whether it started early or late.

It is intended to develop these observations further in a study of the action of vitamin D.

Desorption or 'Surface Melting' of Lubricant Films

A RECENT communication[1] has described the effect of temperature on the lubricating properties of mineral oils. The apparatus used for the experiments was that devised by Bowden and Leben for analysing the frictional force between sliding surfaces. In this apparatus the bottom surface is driven steadily forward, but the upper surface is mounted on a bifilar suspension so that it has a certain degree of freedom and can respond to any changes in the frictional force. Using this apparatus they have shown that the sliding between steel surfaces lubricated under boundary conditions with certain mineral oils and with other lubricants may not be continuous but may proceed by a process of 'stick and slip'. In general, this jerky motion is observed with non-polar lubricants which are not adsorbed or are only weakly adsorbed on the metal surfaces. With certain polar molecules, such as the long-chain fatty acids which form strongly adsorbed layers, the motion changes over to continuous sliding. It was also found[2] that the polar oxidation products which may be present in solution in some mineral oils or which are formed in the oil by heating may act in a similar way and may cause continuous sliding. The experiments described in the previous communication[1] have shown that, if the surfaces are warmed, these adsorbed polar substances may be driven off the surface, and the motion may change over to stick-slip. This transition, which is a reversible one, may occur at quite moderate temperatures, for example, 50° C., and is accompanied by an increase in wear.

These experiments have been continued with a number of pure straight-chain hydrocarbons on steel surfaces. Some of the later measurements were made by Mr. J. J. Frewing. Bowden and Leben's observations[3] that *solid* films of saturated hydrocarbons or of straight-chain alcohols give continuous sliding and that the transition to stick-slip occurs *at the melting-point* have been confirmed. It was also found that *liquid* films of the fatty acids give continuous sliding and that this persists when the surfaces are warmed up. *When the temperature was raised to about 75° C. above the melting-point, however, the transition to stick-slip occurred.* The typical behaviour of a fatty acid is shown in F 1. These results are for lauric acid.

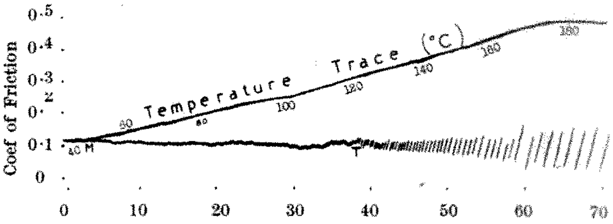

Fig. 1.

The upper trace records the temperature, and the lower trace the friction. It will be seen that at first smooth sliding occurs and the friction is reasonably constant, and there is no change at the melting-point (*M*). At the point *T*, however, the transition to stick-slip occurs. The effect was reversible and, on cooling down, the return to continuous sliding occurred at the same temperature. The measurements were made on a homologous series of fatty acids from pelargonic to stearic and the results are plotted in Fig. 2. Curve I gives the melting point of the samples used, and Curve II the temperature at which the transition from smooth sliding to stick-slip occurred. It will be seen that there is a separation between these curves which is nearly constant and is approximately equal to 75° C.

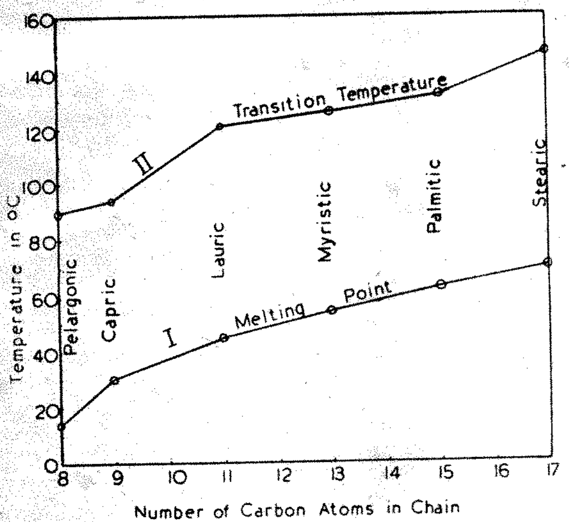

Fig. 2.

It is suggested that the transition from smooth sliding to stick-slip is due to the desorption or disorientation of the adsorbed film or to a change of state from a closely packed to a less closely packed form. The fact that this 'surface melting' of the adsorbed film occurs at a temperature 75° C. above the bulk melting point in the case of the acids, close to the melting point in the case of the corresponding alcohols, and at the melting point in the case of the corresponding hydrocarbons, is interesting. At the melting point of the bulk solid, sufficient kinetic energy is distributed among the molecules to enable them to overcome their attraction for one another. In order to melt the adsorbed film, sufficient energy must be available to overcome this mutual attraction plus their attraction for the surface. The difference between the transition temperature and the bulk melting point may therefore be regarded as a measure of the strength with which the polar group is attached to the steel surface.

The results suggest that this analytical frictional method provides a useful weapon for measuring the strength and for studying the mechanism of the adsorption of various polar groups on to solid surfaces. Apart from their theoretical interest, these observations are of considerable practical importance. If a lubricant contains suitable polar substances it will give smooth sliding and low wear at room temperature but, when the temperature is raised, the adsorbed film responsible for this may be driven off. The temperature at which this occurs may be below 100° C. and may be easily attained by many parts of a running engine. It is clear that this must be taken into consideration, both in the testing of a lubricant and in its selection for practical use.

I am indebted to members of Dr. Bowden's research team in the Laboratory of Physical Chemistry at Cambridge for helpful discussions and to the Petroleum Company for permission to publ work, which was carried out in their laborat

N.W.1.

MR. H. G. WELLS[1] states that he was danger of becoming corruptingly rich by films, and that "Mr. Paul came along to me an out a provisional patent that would have practically the ground landlords of the en industry" (NATURE, April 19, p. 465).

My provisional specification described m presenting the main incidents in Mr. Well "The Time Machine". To create an ill travelling through time spectators were to on a rocking and oscillating platform and to wind and noise effects. Pausing at vario —past, present and future—they were to s priate events shown on a screen by means of photographs and dissolving views. It was t details of such scenes that I invited Mr. my office in Hatton Garden towards th 1895. He listened patiently to my propos his general approval to my attempting to c out, and proceeded to talk of subjects su the primeval scenes. Having recommende perusal some books on extinct monster without further discussion as to future ac many years elapsed before I had the pl meeting him again.

My scheme was promptly abandoned fo which can be guessed by those acquain animated photography in 1895. Then o films could be watched by individuals w through the slot of an Edison kinetoscope its variants. In several countries inventors, myself, were seeking means for showing screen, and such projectors came into us 1896. The simplest scenes, coupled with t of seeing photographs moving, sufficed to a public and to establish the new art of cinem in favour. A prolonged presentation, su of "The Time Machine", was then unnece indeed impracticable.

RESEARCH ITEMS

The Genitalia of Hymenoptera

The morphology of the external genitalia of male insects has received a good deal of attention in recent years, and one of the most active workers in this field is R. E. Snodgrass, of the U.S. Department of Agriculture. His most recent contribution to this subject deals with the male genitalia of the order Hymenoptera (*Smithsonian Misc. Coll.*, 99, No. 14, Washington, 1941, 86 pp., 33 plates). The author concludes, in regard to insects in general, that the primary genital ducts in the male must have opened on the tenth segment of the abdomen. Paired penes, giving individual exit to these ducts in Ephemeroptera and certain Dermaptera, appear to belong to this segment. The median genital organ of other insects is termed by Dr. Snodgrass the phallus, which is formed by the union of a pair of genital lobes arising, in most cases, on the ninth abdominal segment. The nature of the so-called claspers is fully discussed, and while it is conceded that these structures are derived from the phallus in some orders of insects, in others, including Heteroptera, Mecoptera, Trichoptera, Lepidoptera, and Diptera, he says that there is no conclusive evidence as to the nature of the movable claspers borne on the 'coxal plates' in the orders named. In the Hymenoptera the development of the phallus is from a pair of rudiments on the ninth abdominal segment. Characteristic genital features of the order are the lateral parameral lobes or 'valvæ externæ', a median œdeagus, a pair of volsellæ or 'valvæ internæ' and, in bees, the sagittæ or 'penis valves' in addition. All these components are derived from an original phallus, and include no counterparts of the claspers found in those orders listed above.

Incidence of Lice

An investigation has recently been carried out by K. Mellanby at the request of the Board of Education and the Minister of Health with the object of discovering the incidence of the head-louse in England. In a memorandum enclosed with Circular 2306 (Ministry of Health) and Circular 1544 (Board of Education), it is stated that infestation of the body is rare in children. As the result of an examination based on approximately 60,000 cases in hospitals, it is found that a very high degree of infestation with head-lice exists in industrial cities, and that girls are more frequently infested than boys. In industrial cities infestation in girls reaches a peak at three years old (51·6 per cent), and similarly in boys, but at the rate of 40 per cent. In the rural areas the percentage of children infested is very low. There is, it appears, no evidence that louse infestation, though widespread, is increasing. All the evidence points to the fact that education and improved social conditions have resulted in it being less common and less severe than in the past. The conclusion is reached that education of the public is the only method likely to yield permanent success. While local authorities have powers to take appropriate action, it must be premised that the desired improvement of conditions will be secured by a continuous use of administrative measures for treating cases which have arisen and by educational efforts rather than by resorting to powers of compulsion.

Frost Resistance in Plants

In the now voluminous literature on this subject it is evident that two physical factors in the organization of protoplasm are of importance in determining hardiness: the percentage of bound water and the permeability to water. Increase in either of these properties, or of both, is involved in increase in hardiness. Some light is thrown on the relation of these properties to hardiness by Siminovitch and Levitt (*Canadian J. Res.*, 19, 9; 1941) in an investigation of the physical properties of the protoplasm in several hardy and non-hardy species. The surface membrane of non-hardy cells stiffens when dehydrated osmotically and therefore ruptures readily when subjected to tension on deplasmolysis. This stiffening either fails to occur in hardy cells or arises as a result of much greater dehydration. The volume enclosed by the membrane can be reduced in these latter tissues to less than one third of its initial value without any sign of deplasmolysis injury, whereas in non-hardy cells a reduction to only two thirds causes death on deplasmolysis of more than 50 per cent of the cells. A further difference brought to light by these plasmolytic experiments is the clumping of plastids and granules (systrophy) in non-hardy but not in hardy species consequent upon prolonged immersion in a plasmolyticum. With regard to other physical properties, the refractive index of the protoplasmic surface increases more on dehydration in non-hardy than in hardy cells, and oil drops injected into plasmolysed cells readily become crescent shaped in non-hardy cells on deplasmolysis, but not so readily, if at all, in hardy cells. All these facts indicate a greater hydrophily in hardy than in non-hardy species both of the surface membrane of the protoplasm and, possibly to a lesser extent, of the protoplasm as a whole. This is obviously in harmony with the above-mentioned views concerning bound water and permeability.

Lily Mosaic

The ninth volume of the Royal Horticultural Society's Lily Year Book (from the Society's office, Vincent Square, Westminster, S.W.1; 1940, 5*s*. paper, 6*s*. cloth) contains a useful review by D. E. Green and M. A. H. Tincker of the damage caused to lily plants by the mosaic virus. Many species of the genus Lilium frequently show the characteristic leaf mottling symptoms of the disease, which usually destroys a stock within three or four years. Malformation and dwarfing of the flowers is also found, with diminution in size of the bulbs. The malady is distributed by the insect vector *Aphis gossypii*, which can be largely controlled by frequent application of nicotine dust. Infection by the virus often occurs in the seedling stage, though the disease is not truly seed-borne. *Lilium speciosum* and *L. auratum* were the host species particularly studied, and stocks of the former survived for a longer period at Wisley than did the latter, which is very susceptible.

Rust-Resistant Antirrhinums

D. E. Green reports progress on the selection of strains of Antirrhinum resistant to the rust fungus *Puccinia Antirrhini*, in a recent short paper (*J. Roy. Hort. Soc.*, 66, Pt. 3; 1941). Resistant forms were obtained from the United States, but were not florally desirable; the problem was first to select a series of parent forms with flower colours suitable for decorative combination. This has now been accomplished, and five rust-resistant strains of varying flower colour have been established. It is not yet known if they are resistant to a second physiological race of the parasite which has appeared in the United States.

Trisomics in Nicotiana

T. H. Goodspeed and P. Avery (*Proc. U.S. Nat. Acad. Sci.*, **27**, 13–14; 1941) have found the twelfth primary trisomic in *Nicotiana sylvestris* ($n = 12$). This trisomic, Stiff, has extremely long flowers and stiff leaves which easily distinguish it from the diploid and the other eleven known primary trisomics. Stiff arose from the cross $3n - 1 \times 2n$ as a double trisomic with Puckered. This in turn gave 24 diploid, 12 Puckered, 14 Stiff and 3 double trisomics. Stiff has also arisen from the progeny of an asynaptic form of the trisomic Inflated.

Determination of Arsenic

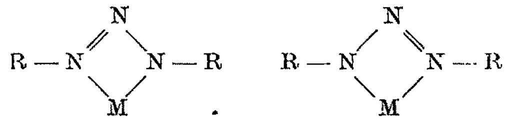
At a meeting of the Society of Public Analysts and other Analytical Chemists held on February 5 H. J. G. Challis described the interference of selenium and tellurium with the determination of arsenic by the hypophosphorous acid method. In the method of B. S. Evans for the determination of arsenic by separation with hypophosphorous acid and subsequent iodimetric titration, if selenium or tellurium is present errors are caused inasmuch as these elements also are precipitated by hypophosphorous acid and are oxidizable by iodine. To avoid these errors a modification of the method is described in which the hypophosphorous treatment is carried out first at 50° C. for half an hour. This precipitates selenium and tellurium but not arsenic, and after filtration the arsenic is precipitated from the filtrate at boiling temperature as described by Evans.

Underground Water Supply of Calcutta

An inquiry from the Corporation of Calcutta as to the nature of the strata below the Gangetic delta, arising from a proposal to install deep tube-wells, led to the preparation by A. L. Coulson of Water Supply Paper No. 1 (*Mem. Geol. Surv. India*, **76**, 150; 1940) which contains a systematic account of all the relevant information. After a general description of the Indo-Gangetic plains and the Ganges delta, the question of the maximum thickness of the alluvium and the discrepancy between the geological evidence and that afforded by geodetic observations is discussed. Theories are given for the origin of the 'swatch of no ground' off the Ganges delta. Detailed information gained from the sinking of tube-wells in Calcutta and its vicinity during the last 135 years is compiled. It is pointed out that the rate of flow of the underground water is slow and that considerable mutual interference must be expected between wells sunk too close together. As to the sources of the water, it is concluded that while there is a south-easterly flow from the Damodar river, the bulk of the underground supplies is replenished by slow southward percolation from the Brahmaputra and Ganges. It is pointed out that there is some danger of exhausting the supplies if numerous wells are sunk to tap the aquifers. It is recommended, however, that an experimental tube-well boring should be sunk to a depth of 5,000 feet or less, according to whether or not the basement rocks underlying the Gangetic alluvium are encountered before that depth is reached. A gradual coarsening of the beds with depth is expected, until the Tertiary marine strata or the Supra-Panchet rocks are struck. It is the gravel beds—if these are proved to exist—immediately overlying the basement rocks that will most likely furnish water under artesian conditions.

Metallic Triazine Complexes

The preparation of a number of metallic salts of diazoamino compounds and the determination of their molecular weights, by F. P. Dwyer (*J. Amer. Chem. Soc.*, **63**, 78; 1941) show that they should be formulated as inner complex salts in which the triazine group functions as a chelate (2-co-ordinating) group, and with the possibility of resonance (leading to stability) between the two structures:



Two compounds prepared appear to be the first examples of hexacovalent palladous compounds described, the triazine groups being probably octahedral about the metallic atom in *cis* positions. F. P. Dwyer and D. P. Mellor (*J. Amer. Chem. Soc.*, **63**, 81; 1941) by magnetic susceptibility measurements show that nickel complexes of diazoaminobenzene and 4-4′-dimethyldiazoaminobenzene are diamagnetic and hence in them the nickel atoms have a square co-ordination configuration. In that case the triazine group appears to function as a chelate group. Molecular weight determinations show that two deep red diamagnetic complexes are dimeric in benzene; on boiling, this structure gradually breaks down into the monomeric form, the change being reversed on cooling. The dimeric forms involve an 8-membered ring of nitrogen atoms bridging the nickel atoms which is very unusual, although there is evidence for its occurrence with *bis*-ethylenediamine cobalt complexes with sulphonyl diacetic acid and with homophthalic acid.

Crystal Structure of Iodic Acid

An X-ray examination of the structure of the α-modification of crystalline iodic acid by M. T. Rogers and L. Helmholz (*J. Amer. Chem. Soc.*, **63**, 278; 1941) shows the presence of discrete pyramidal IO_3' groups in the crystal with the observed I–O distances 1·80 A., 1·81 A., and the O–I–O angles 96°, 98° and 101°. Three oxygen atoms in positions approximately opposed to the three-bonded IO_3 oxygens and at distances 2·45, 2·70 and 2·95 A. complete a distorted IO_6 octahedron with three strong bonds and three weaker ones. The hydroxyl oxygen atom of each iodate group has two nearest oxygens at 2·78 A. There are thus two hydrogen bonds for each iodate group forming a moderately strong bifurcated bond. The oxygen atoms are in a somewhat distorted closest packed arrangement and the structure somewhat resembles that of perovskite. Crystalline iodic acid is an aggregate of HIO_3 molecules held together by hydrogen bonds, and secondary I–O bonds of the type observed for arsenic and oxygen in arsenolite.

Stability of Crystal Lattices

IN the fifth of a series of papers, R. Fürth (*Proc. Camb. Phil. Soc.*, **37**, 34; 1941) deals with the relation of some experimental results and recent theories of the equation of state and the melting of solids. After a short survey of Born's theory of the thermodynamics and melting of crystals it is shown that Lindemann's and Grüneisen's law for the normal melting temperature can be deduced. Values in good agreement with experiment are got for the dependence of the melting temperature on pressure and for the dependence of the compressibility and elastic constants on pressure and temperature. Several connexions between breaking and melting, suggested by the fundamental ideas on melting and stability of crystals, are discussed and verified. A relation between heats of melting and of sublimation gives values of the correct order of magnitude (see also NATURE, **145**, 741; 1940).

Reagent of Aldehydes

A 1 per cent solution of N,N-dibenzyl-*m*-phenylenediamine in 95 per cent alcohol is proposed as a reagent for aldehydes by F. G. Singleton and C. B. Pollard (*J. Amer. Chem. Soc.*, **63**, 240; 1941). The test is carried out by placing two drops of the substance in a test-tube and adding 5 ml. of the reagent. Saturated aliphatic aldehydes give a red initial colour followed within ten minutes by a bright green fluorescence which becomes stronger on standing; formaldehyde is exceptional in giving a yellow initial colour and no fluorescence. Unsaturated aliphatic aldehydes give a darker red initial colour than saturated, and a dull brownish-green fluorescence appears within ten minutes; hexadiene-2,4-al and cinnamaldehyde show unusually dark red initial colours but no fluorescence. Aromatic aldehydes give initial colours which vary from bright yellow to dark red, and a bright green fluorescence appears only after two or three hours.

Long-Chain Polar Compounds in Lubrication

THE effect of long-chain polar compounds on the coefficient of kinetic friction under boundary conditions has been studied by O. Beeck, J. W. Givens and A. E. Smith (*Proc. Roy. Soc.*, A, **177**, 90; 1940). The Boerlage four-ball friction apparatus in various modifications was used, and the structure of thin films of lubricants rubbed on polished mild steel surfaces was examined by electron diffraction. For oils which showed high surface orientation imparted by addition of long-chain polar compounds, a sudden decrease of the coefficient of friction was observed at various velocities of the sliding surfaces, depending upon the compound used. Those compounds in which the effect occurred at the lowest velocities were found to be most highly oriented with their carbon chains most nearly perpendicular to the surface. At the regions of sudden decrease of the coefficient of friction the electrical resistance between the sliding surfaces changes from a low value, corresponding to metallic contact, to an extremely high value. The effect is explained as a 'wedging' of oil under the surface.

The Ellipticities of the Earth and Moon

JEFFREYS has recently combined six data relevant to the ellipticities of the earth and moon and found the agreement satisfactory (*Mon. Not. Roy. Astro. Soc.*, 101, No. 1; 1941). These are the secular motions of the node and perigee, the monthly term in the moon's latitude, the inclination of the moon's axis, the annual libration in longitude and a new determination of the ellipticity term in gravity recently made by Jeffreys himself. Following work by Brown and Spencer Jones, and using Belkovitch's solution concerning f in preference to that of Franz and Stratton, Jeffreys obtains:

$$J = 0{\cdot}0016377 \pm 0{\cdot}0000042\ (0{\cdot}0000062\ s.e.)$$

giving $\frac{1}{\varepsilon} = 297{\cdot}05 \pm 0{\cdot}38$ (0·56 *s.e.*). This value has about the same apparent accuracy as Heiskanen's and the international gravity formula (Potsdam standard) is modified to

$$g = 978{\cdot}049\,(1 + 0{\cdot}0052895 \sin^2\varphi - 0{\cdot}0000059 \sin^2 2\varphi).$$

It has been suggested by Browne and Bullard that the first factor should be 978·032 but that the change should not be made until the connexions between Potsdam, Cambridge and the National Physical Laboratory have been strengthened. According to Jeffreys the constants for the moon are now:

$$J + \tfrac{1}{2}K' = 0{\cdot}0003733 \pm 0{\cdot}0000011\ (0{\cdot}0000016\ s.e.)$$
$$K' = 0{\cdot}000073 \pm 0{\cdot}000023\ (0{\cdot}000034\ s.e.)$$
$$f = 0{\cdot}804 \pm 0{\cdot}062\ (0{\cdot}092\ s.e.)$$

An outstanding difficulty is still the disagreement between the moon's dynamical and visual parallaxes, which Jeffreys suggests may be due to an abnormal deflection of the vertical at Cape Town.

The Ellipticity Term in Gravity

JEFFREYS has recently made a new estimate of the main ellipticity term in gravity (*Mon. Not. Roy. Astro. Soc.*, Geophys. Supp., **5**, No. 1; 1941). Taking the existing observations of gravity over the surface of the earth, forming summaries of the free air anomalies over 10° squares and reducing to the mean height of the square so as to eliminate the correlation of the free air anomaly with height, it was hoped to determine the harmonics of low order other than the main ellipticity term. It was found that the observations were unsuitably distributed for such a determination owing chiefly to lack of data for the South Pacific and high southern latitudes, but they did yield a new estimate of the main ellipticity term in gravity. This ellipticity turned out to be the reciprocal of 296·80 ± 0·71.

Diffuse Radiation in the Galaxy

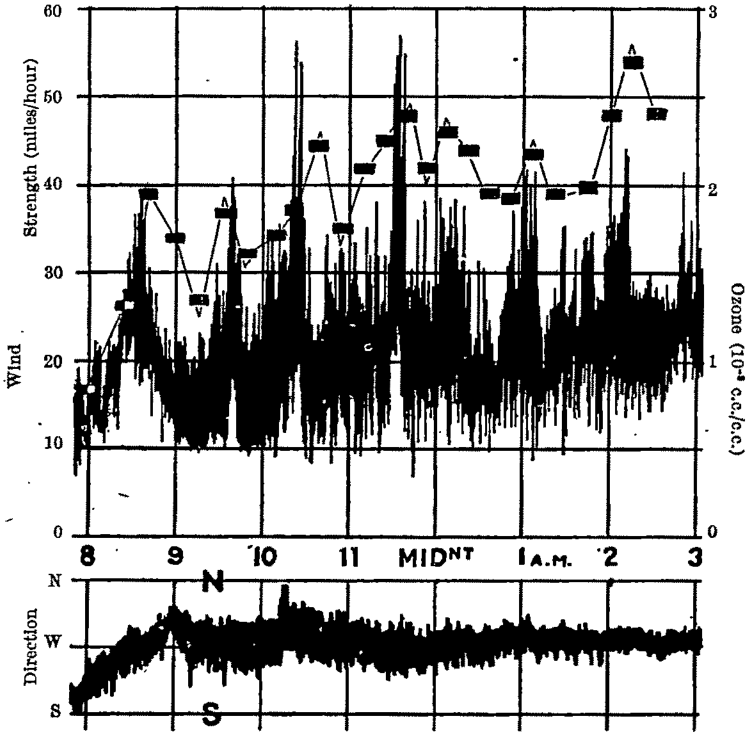
THE so-called interstellar 'absorption' of light which gives rise to the dark nebulæ is likely to be (at least in part) scattering rather than absorption. This being so, those regions of the Milky Way rendered least luminous to the naked eye because the light of distant stars is absorbed should show a faint background of diffuse light due to scattering by the interstellar particles. This has been recently verified by Henyey and Greenstein (*Astrophys. J.*, **93**, 70; 1941), who used for the purpose a Fabry photometer attached to the 40-in. refractor of the Yerkes Observatory. Surface brightnesses of the sky were measured photographically across the Milky Way at several points, choosing fields free from stars brighter than mag. 16 so as to reduce the correction for unresolved starlight. After correcting for the light of faint stars, for direct and scattered auroral light, and for zodiacal light, these observations indicate a diffuse radiation concentrated closely to the galactic equator and reaching there a value equivalent to some 60 tenth-magnitude stars per square degree; more in the dark regions, less in the transparent areas. This diffuse light can be explained as scattered stellar radiation if the phase function governing the scattering is strongly forward-throwing.

MEASUREMENT OF ATMOSPHERIC OZONE BY A QUICK ELECTROCHEMICAL METHOD

BY PROF. F. A. PANETH AND DR. E. GLÜCKAUF

CHEMISTRY DEPARTMENT AND OBSERVATORY, UNIVERSITY OF DURHAM

AT a conference held at Oxford in September 1936 the need for a chemical method of determining atmospheric ozone, and the objections against those applied so far, were discussed[1]. Two years later a procedure was described which avoided the earlier drawbacks: by condensing ozone on cooled silica gel it was possible to reach a concentration sufficient for safe identification by specific reagents and absorption spectrum, and for a reliable titration[2]. The process is, however, cumbersome, and the hope was expressed that, after establishing this trustworthy method by which to test others, a much simpler one might be found sufficiently exact for meteorological purposes[3].



The method described here seems to meet this requirement; it is at the same time very fast and continuous and lends itself to automatic recording. Its main features are: (1) the atmospheric ozone is absorbed in a potassium iodide solution under conditions which exclude wall reactions; (2) the liberated iodine is measured by its depolarizing effect on platinum electrodes; (3) the periodic addition of constant quantities of thiosulphate restores the initial conditions and makes it possible to take ozone readings every two minutes or so, unless the atmospheric ozone concentration is much below average.

The course of the chemical reaction between ozone and iodide is influenced by the presence of a glass surface; this heterogeneous reaction is responsible for the production in neutral solutions of iodate, besides iodine, and for the catalytic decomposition of part of the ozone[4]. In our apparatus the air enters at high speed through a nozzle, thereby spraying potassium iodide solution vigorously throughout the reaction vessel and bringing ozone and liquid in close contact without interference of the glass walls. The reaction of ozone with the fine spray of buffered neutral solution is found to be quantitative even at concentrations as low as 10^{-8} c.c. of ozone per c.c. of air, and is apparently entirely homogeneous, as no iodate is formed. The sprayed liquid is collected and, by the suction of the nozzle, circulated back to the inlet tube; on its way it flows rapidly over two platinum electrodes having a potential difference of 10 mv. An electric current can pass only if the cathode is depolarized by an oxidizing agent[5]; free iodine of less than a millionth normality permits the passage of currents easily measurable by a galvanometer. This apparatus achieves the absorption of ozone from air, passing at the rate of about 1,000 litres per hour, with 15 c.c. of potassium iodide solution; the evaporating water is replaced by using a highly diluted (*N*/2,000) solution of thiosulphate for titration.

We have tested the reliability of the new method by carrying out a parallel determination with the condensation method by which ozone is separated from nitrogen dioxide[2]. It was found that there was no nitrogen dioxide present, and the ozone values agreed within 2 per cent. Moreover, tests have shown that, under the conditions of our procedure, nitrogen dioxide liberates very little, if any, iodine from a neutral potassium iodide solution; thus the method is practically specific for ozone.

We hope to employ the method for a systematic study of the occurrence of ozone in the troposphere and lower stratosphere. So far we have investigated its dependence on the intensity and direction of local winds. More than seventy years ago a connexion between ozone concentration and wind was announced[6]. It was rediscovered several times[7]; quite recently the application of a micro-method[8], based on the principle of passing air over, instead of through, a potassium iodide solution[9], rendered it possible to follow fairly quickly the effects of wind changes[10]. We made use of our faster and simpler method, and of the facilities offered by the University Observatory—situated about one mile to the south-west of Durham

City—to compare closely ozone and anemometer readings taken on the same spot.

It was found that winds from the north-east, coming from Durham City, never contained ozone; on the contrary, our apparatus showed the presence of reducing substances (probably sulphur dioxide from burnt coal) which were not detectable—even after destruction of ozone with active charcoal—in westerly winds. These winds, if exceeding 5 miles per hour, nearly always contained ozone. Stagnant air had none, but showed reducing qualities. The parallelism between ozone content and wind velocity was most impressive on days with heavy gusts of westerly wind. The accompanying figure is a reproduction of the Dines anemometer record for the night of December 5/6, 1940, on which the ozone values are inserted (the length of the markings indicates the duration of the measurements); it can be seen that every ozone maximum follows closely on a series of high gusts, a time lag of a few minutes being noticeable.

The reality of such a time lag—easily understandable—was also clearly shown when the wind suddenly, and for a considerable time, changed its direction (see the following table giving anemometer and ozone values for March 21, 1941). It took several minutes before the ozone-containing air masses had been swept away after sudden veering of the wind to the north-east.

Time Interval G.M.T.	Direction	Wind Velocity (miles/hr.)	Ozone content (in 10^{-8} c.c./c.c. air)
10.31 to 11.10	W.N.W.	20 to 15	3·6, 3·0, 3·1, 2·8, 3·6, 2·9, 2·9
11.10 ,, 11.13	sudden change to N.E.		2·3
11.13 ,, 11.17	N.E.	15 to 12	3·6, 3·1
11.17 ,, 11.19		12	rapid fall to $< 0 \cdot 1$
11·19 ,, 11.45		12 to 10	$< 0 \cdot 1$

There are, however, observations which indicate changes others than those due to local contamination. Early during the depression of December 5, 1940, the ozone concentration decreased from $2 \cdot 1 \times 10^{-8}$ to zero more than two hours before the thermograph showed the arrival of a warm front, the wind being south-south-west the whole time, and even gaining in strength; the quick rise of the ozone to $1 \cdot 9 \times 10^{-8}$ at 8.40 p.m. (visible in the figure) was accompanied by a turning of the wind to west and closely followed by the passage of a cold front. Similar observations were made during depressions on November 20 and 27 and December 10. Such measurements, if carried out in regions free from artificial contaminations, may be as helpful for the study of large-scale turbulence in the troposphere[11] as that of 'ozone clouds'[12] in the stratosphere. Another fact already emerging from the data collected is an increase of about 100 per cent in the average ozone content from November 1940 to March 1941; this constitutes an obvious parallelism with the spectrographic measurements of the total ozone in the atmosphere[13] and thus seems to confirm the views about a correlation between tropospheric and stratospheric ozone[14].

A fuller description of the procedure and results will be published later.

We desire to express our thanks to the Department of Scientific and Industrial Research for a grant; to the curators of Durham University Observatory for providing facilities to work there; and to Mr. P. R. Monk for his help in preliminary experiments carried out in 1939 at the Imperial College in London.

INFLUENCE OF GEOLOGY ON THE HEALTH OF GRAZING ANIMALS

By Dr. George Dunlop and Dr. W. J. McCallien

A SURVEY has been made in south-west Scotland of the distribution of vinquish, a debilitating disease of sheep referred to by Aiton in 1810 as being prevalent in this area. The disease shows certain affinities to coast disease of South Australia (1), wasting disease of Western Australia (2), bush sickness of New Zealand (3), nakuruitis of Kenya (4), moor cling of Devon (5), pining of the Scottish borders (6), salt sickness of Florida (7), pine of the Hebrides (8), and neck ail of Massachusetts (9).

The geological features of the areas on which these deficiency diseases occur are varied but can be grouped as follows: (*a*) æolian deposits of sand and comminuted shell fragments (1, 7, 8, 9); (*b*) granite and other igneous intrusions and lavas (2, 3, 4, 5); (*c*) areas geologically complex (6).

Following the work of Marston and his colleagues[10], it was shown that the daily administration of small amounts (< 1 mgm.) of cobalt quickly cured animals suffering from certain of these maladies (2, 3, 4, 5, 6), copper as well as cobalt was essential for the cure of (1), iron and copper for (7), and iron alone for (8, 9). In curative experiments on vinquish a daily dose of 40 mgm. iron + 10 mgm. copper was administered to 16 animals, of 10 mgm. copper to 17 animals, and of 1 mgm. cobalt to 21 animals. Cobalt alone was effective, all the animals recovering quickly from the disease. It appears, therefore, that vinquish in our area is a straight cobalt deficiency.

The accompanying diagram (Fig. 1, below) illustrates the distribution of vinquish in south Ayrshire. Comparison of this diagram with the geological sketch-map (Fig. 1, above) at once suggests a fairly close relationship between the disease and the geology of the region. The exact nature of this relationship is not yet known, but it is worth considering at this stage of the investigations.

The Southern Uplands Fault is the most conspicuous structural feature of our area. The sharp division of vinquish from non-vinquish grazings along the line of the fault may be illustrated by the following examples :

(*a*) Vinquish is unknown on farms with the fault as their northern march.

(*b*) Farms with the fault as their southern boundary are affected.

(*c*) Where the farm extends across the fault the hefts to the north are affected and those to the south are clear. (A heft is a group of sheep—usually 3–8 score—grazing together within natural boundaries.) Near the head of Loch Doon, a hirsel, comprising four hefts, stretches across the fault. On the most westerly heft there is only a small proportion of ground to the north of the fault, but this proportion increases with each heft until on the most easterly the grazing is largely on the north side. Cases occur sporadically among the first lot of ewes, but the number of affected sheep increases on each heft to the east until the most easterly is regarded as bad pining ground.

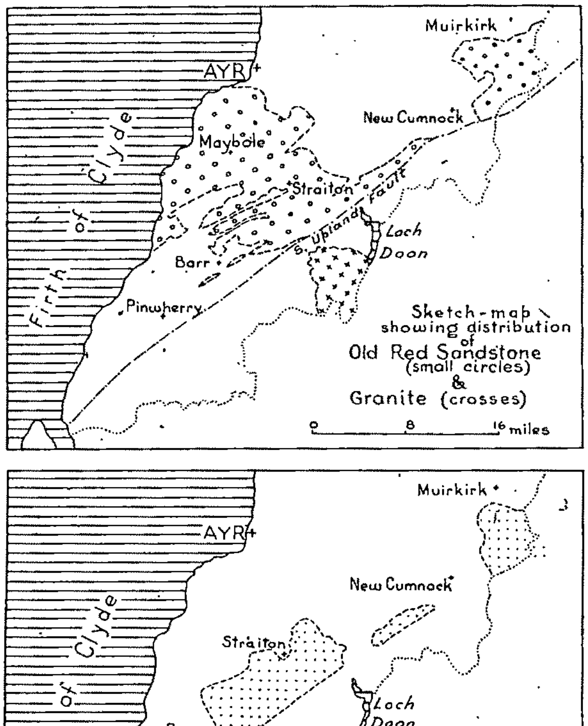

Fig. 1.

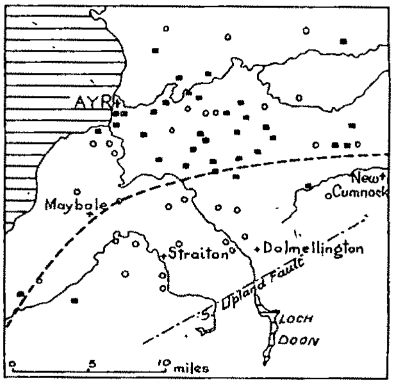

Fig. 2.

DRIFT AND MINERALOGICAL SKETCH MAP OF SOUTHERN AYRSHIRE.

Heavy broken line : boundary between northern and southern drifts. Black rectangles : soil carrying more than 2·9 per cent heavy crop. Circles : soil carrying up to 2·9 per cent heavy crop. Based on Elder and McCall.

In the area at present under review the Southern Uplands Fault separates the Upper Palæozoic rocks of the Midland Valley from the Lower Palæozoic of the Southern Uplands. The Upper Palæozoic consists chiefly of Old Red Sandstone sediments, andesitic lavas, and intrusions. These all support vinquish grazings, but the disease is most severe on areas of felsite and related intrusions.

The northern boundary of the vinquish areas is defined partly by the appearance in this direction of arable farms. Where hill sheep farms exist the grazings to the north of the dotted areas in Fig. 1, below, are free from vinquish.

The northern boundary appears to coincide with the junction of the drifts of northern and southern origins as determined by the Geological Survey. The difference in the mineralogical composition of these drifts is marked. Mineralogical analyses by Elder and McCall[11] have shown that the ferromagnesian crop from the soils on the northern drift average 4·6 per cent, while on the southern drift the percentage is invariably lower (Fig. 2). It is noteworthy that the soils from the vinquish farms of Auchenroy, Shaws Knowe, Grimmet, and Straiton Moor contain the lowest percentage of ferromagnesian minerals—1 per cent or less.

From what has been said above it seems that there is a close connexion between the geology and the health of the grazing animals and that the Southern Uplands Fault in the region studied in greatest detail (Tairlaw and Knockdon) forms the demarcation between the vinquish-affected and the healthy areas. Field study suggests that the differences in the solid geology are not entirely responsible. Considerable tracts of Old Red Sandstone in the Straiton region are composed of andesitic lavas relatively rich in iron and, therefore, presumably also in cobalt. In the area south-east and east of Barr the rocks on the two sides of the Southern Uplands Fault are the same, yet the vinquish map shows the same contrast between vinquish and healthy districts as in those parts where the Old Red Sandstone occurs on one side of the fault and the Lower Palæozoic on the other. We have come to the conclusion, therefore, that the nature of the drift is largely responsible for the incidence of the disease.

In general, the Southern Uplands Fault separates a mountainous belt from the comparatively low ground of the Midland Valley. The difference in topography, a conspicuous feature in the landscape of the Knockdon area, may in itself be a factor bearing on the present problem. It has at least been responsible for the restriction of the morainic drift to the country south of the fault and of the boulder clay to the more fertile ground to the north. The boundary between the two types of drift does not actually coincide with the outcrop of the fault, but the disease boundary line may not really coincide any better. One reason behind the distribution of the disease may, therefore, be the physical state of the subsoil, for the two types just mentioned, morainic drift and boulder clay, have been derived from the same parent rocks to the south.

The occurrence of vinquish on the felsitic outcrops indicates that in certain cases in our area there is a direct relationship between rock, subsoil, soil, herbage and morbid condition of the grazing animals.

WHAT IS A PHYSICIST?

DURING the War of 1914–18 a physics student applied for postponement of military service to enable him to sit for his university examination. One member of the tribunal asked if the student would not be better occupied at a base hospital. Nobody saw the connexion until two words of explanation were given—"mixing physic". At the same time rumour had it that certain physicists working on radio-telegraphy were described officially as chemists because the Services had not officially heard of the term physicist. More recently the literature of popular science has helped to spread the idea that a physicist is essentially a splitter of atoms. In a leading article in the November number of the *Journal of Applied Physics*, published by the American Institute of Physics, fears are expressed that the services of physicists are liable to be neglected because service and business officers are still under the impression that physicists "being only interested in atoms" cannot be expected to be of much assistance.

The definition given by the Institute of Physics in Great Britain to the Ministry of Labour and National Services' Central Register was as follows: "A Physicist is one who has knowledge of, and experience in, one or more branches of physics. Physics includes the study of (1) the properties and nature of matter, (2) heat, (3) light (optics), (4) sound (acoustics), (5) electricity, (6) magnetism, (7) radio-activity; and their applications. *Note.* The technical application of certain branches of physics have become branches of engineering." With the Schedule of Reserved Occupations, the Ministry of Labour and National Service uses the definition: "*Physicist*—is engaged in the study of matter and its general properties as affected by the application of various forms of energy; may be specialized, e.g., in mechanics, heat, light, sound, electricity, radio-activity; the usual qualification is membership of the Institute of Physics and/or a University degree."

When the order for compulsory registration was made in July 1940 any person was considered a physicist who possessed an honours degree in physics of any university of the British Empire, and who was normally engaged as a physicist at any university or in any industry or as a teacher of physics. The number registered under that order was 1,175. Previously, 1,596 persons had registered voluntarily as physicists. Not only in Great Britain is there a scarcity of physicists. In the United States, according to an announcement in the February number of the *Review of Scientific Instruments*, the U.S. Civil Service Commission had to extend the closing date for receipt of applications for entry to the civil service examinations for physicists. The salaries attached to the posts were: physicist (any specialized branch), 3,800 dollars a year; principal, 5,600 dollars; senior, 4,600 dollars; associate, 3,200 dollars; and assistant, 2,600 dollars a year.

The difficulties of creating physicists when they are wanted for work in applied physics is perhaps difficult to realize for those who claim to be able to make a soldier from a civilian by giving him ten weeks' training. In its twenty years of life the Institute of Physics in Great Britan has worked hard in urging the importance of physics in industry. This work of national importance has had to be carried out at the cost of members of the Institute. That such work places a severe strain on the resources of the Institute is clear from the difficulties of the American Institute of Physics. Details of the help given by the Chemical Foundation to get the Institute safely launched were given in the thirteenth number of the *Rheology Leaflet*. When the help ceased, a deficit of 21,845 dollars had been accumulated by December 1937. In 1939 this had been reduced to 12,840 dollars. Now the Rockefeller Foundation has generously helped. In the same number of the *Review of Scientific Instruments* it is reported that "a drastic decline in foreign dues and subscription income caused by the War in Europe has now threatened to cancel the gains which have been made. In response to the Institute's appeal on this account, the Foundation has generously granted the sum of 20,000 dollars to assist the Institute to adjust the publication program to the new circumstances." In the preparation for, and prosecution of, wars the nations seem to have no difficulty in finding huge sums of money. Yet the bulk of research is still carried on by the aid of charity. The dearth of physicists and the financial difficulties of publication are not therefore surprising. On consideration, it is an odd state of affairs that the publication of scientific work benefiting, or at least used by, the whole world should still be paid for largely by the research workers themselves through their subscriptions to scientific societies.

BANANA FERTILIZER INVESTIGATIONS IN JAMAICA

INVESTIGATIONS of the effect of fertilizers on bananas are few in number, particularly in the great producing areas in the Caribbean region. In Jamaica, where many estates have been long under cultivation, and where Panama disease and soil erosion are tending to force cultivation on to new areas of lower fertility, a full knowledge of fertilizer requirements is rapidly becoming of paramount importance. The results of recent investigations by Croucher and Mitchell (*Bull.* 19, Dept. Sci. and Agr., Jamaica, 1940) are of both theoretical and practical interest, touching as they do on several aspects of the growth requirements of the Gros Michel banana.

The experiments under discussion were begun in 1932, but a succession of hurricanes and droughts prevented the reaping of several of the earlier crops, affording, incidentally, some impression of the difficulties with which the tropical investigator has to contend. The experiments undertaken were of a qualitative type, designed to give information on the general reaction of the banana to applications of the main plant nutrients. In the four different areas selected for experimental plots, different results were obtained: in one a growth response was obtained from nitrogen applications alone; in a second, response was obtained only when potash was applied, but phosphate improved production in the presence of potash; on the other hand, excess phosphate in the absence of potash adversely affected the quality of the fruit produced; in a third area, response was obtained only when phosphate was applied, but, in the presence of this nutrient, further response resulted from applications of potash and nitrogen; in a fourth area, absence of potash precluded the possibility of obtaining commercial fruit.

This brief statement of some of the results so far obtained indicates the wide and useful field that awaits further exploration. The assessment of yield of bananas is not a simple matter, in that it involves a consideration of (*a*) the number of 'hands' per bunch, (*b*) the quality of the individual fruits, (*c*) the rate of production, and (*d*) the population of plants per acre. In some areas nitrogen applications produced an increase in the length of individual fruits—a desirable commercial feature; in others, applications of nitrogen and phosphate also increased the length of fruits, whereas adverse results were obtained elsewhere; potash applications tended to offset undesirable effects resulting from phosphate fertilizers.

FORTHCOMING EVENTS

[*Meeting marked with an asterisk is open to the public.*]

Monday, May 19

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 5 p.m.—Dr. Hugh Scott, F.R.S.: "Highlands of Central Ethiopia".

Tuesday, May 20

ROYAL INSTITUTION OF GREAT BRITAIN (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Joseph Barcroft, F.R.S.: "The Development of Function in the Mammalian Organism".*

Saturday, May 24

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Anniversary Meeting.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

MAINTENANCE ENGINEER by the British Guiana Government Transport and Harbours Department—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1 (quoting M/9393).

ASSISTANT ENGINEER for the Government Federated Malay States Railways—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1 (quoting M/9618).

REGIONALISM IN ADMINISTRATION

THE extension of rationing, the concentration of industry, the changes in reserved occupations, and the registration of women must have brought home to everyone the vital part which the civilian population has to play in the present struggle; but that contribution must be seen in its true perspective. Whether in offence or defence, the striking power of the armed forces depends upon the maintenance of supplies. That is not a matter for the armament factories alone; it involves also the agricultural worker and others concerned with food production, and those who operate the transport services and other essential services in our industrial and national life. It is for the Government to determine as wisely as possible the exact balance between the distribution of man-power in the armed forces, munitions and other essential services for maintaining the national life, and this the policy of concentration and limitation of supplies is designed to promote. Once that balance has been struck, the development of full fighting power depends primarily upon maintaining health and morale and the maximum efficiency. Enemy air attacks on Great Britain have been directed as much against health and morale as against production.

Political and Economic Planning (P E P) has recently issued a valuable broadsheet entitled "London under Bombing", which directs attention not only to important specific issues but also to the wider problems involved in the readjustments of its life that the civil population is being compelled to make, and it does not fail to point out that in this greater plasticity lies one hope of the emergence of a better order. Artificial administrative boundaries, especially between the various parts of a single large town or urban cluster, can no longer be maintained. Regional organization of local services is gaining strength, and local organization is losing it. The whole-time administrator responsible to a higher authority is replacing the spare-time committeeman responsible to voters who may or may not vote occasionally either for or against him. The rigidity of class barriers has been diminished in the armed forces, in civil defence services, through evacuation schemes and otherwise, and the lack of balance between the material and the spiritual values of civilization has been sharply redressed. The nation has learnt that a vigorous social purpose is not only a source of satisfaction but also a source of strength and comfort.

Contrasting the experience of bombing with anticipations, the broadsheet refers to the way in which some technical surprises have played a part in determining the nature of London's problems during the last few months. The extensive use of the delayed action bomb has resulted in some unexpected transport problems due to traffic diversions, and in large numbers of temporarily homeless persons. It has also shown that bomb disposal squads were understaffed. Bombing has also stressed not only weaknesses in the civil defence services but also weaknesses in the whole system of the government of London. The existence of ninety-five separate local government authorities in the London Civil Defence Region has not led to the most effective action in dealing with the social consequences of bombing.

Once the *Blitzkrieg* has failed, the objective of enemy attack, as already indicated, becomes the general dislocation of war effort. The task of civil defence is to take the necessary steps to minimize the harmful effect of attack, and to put into action wider measures required to adapt the civilian population to an environment partly conditioned to the danger of attack.

With regard to direct action, the only possible generalization is that the A.R.P. services have worked well. A suggestion which calls for careful consideration is the provision of a service of welfare wardens whose business would be to reach the scene of an 'incident' as quickly as possible in order to direct people to rest centres, and look after the needs of those who take temporary refuge elsewhere. Such a service is actually in operation in Birmingham and some other provincial cities, and it might be embodied in the existing wardens' organizations. Other provisions to deal with social rather than physical casualties also require strengthening. Rest centres, billeting, re-housing and house-repairs have an important contribution to make to the maintenance or restoration of health and morale.

With regard to shelters, criticism in the last six months has been directed more at the low standard of amenity than at the low standard of protection. If a policy of dispersal had been faithfully followed in practice, there would have been no amenity problem. While in many shelters opportunities for communal activity have been used, and attention is being given to recreation and study—more than four hundred evening classes are being run in shelters by the L.C.C.—the most important aspect of the provision of amenities is that of health.

The seriousness of this question of health is well brought out by one of the most important sections of the broadsheet. It is not merely that many thousands of Londoners spend their nights either in overcrowded, uncomfortable and dirty public shelters, or in cold and damp shelters of the Anderson type. The resistance of Londoners to illness is also being reduced by rising food prices and rationing, by longer hours and less holidays. Moreover, bombing constitutes a direct threat to health through damage to water-mains and sewers, leading to risk of the dissemination of typhoid and paratyphoid fevers. The interruption of services such as water, gas and electricity leads to lower standards of cleanliness and personal hygiene.

The impairment of individual resistance in ways such as these, coupled with the depletion of health services by withdrawal of personnel or commandeering of premises, is likely to lead to unusually widespread dissemination of air-borne infections, especially coughs and colds, influenza and pneumonia, streptococcal infections and cerebrospinal fever. Up to the end of 1940, the condition of London in respect of air-borne infections was generally satisfactory. None the less, abatement of overcrowding by providing more shelter space and air per person, disinfecting the air and mechanical obstruction of the dissemination of respiratory 'droplets' by the use of mouth masks are measures which should be encouraged.

Besides such measures in the shelters, there are broader measures of combating infection. Resistance to infection could be built up by measures of mass immunization as well as by protective foods and adequate rest, and the chances of infection should be minimized by intercepting infectious cases before they reach the public shelters, as well as by detecting infectious cases in the shelters and isolating them as quickly as possible. The importance of communal feeding in maintaining individual resistance under these conditions is obvious. This question involves close co-operation with the Ministry of Food as well as with the Welfare Department of the Ministry of Labour and National Service.

The problem of health, like that of evacuation or of industrial mobilization, cannot be dealt with in isolation. It must be handled against the broader background of the national life. The needs of the inhabitants of large cities under intensive air attack cannot be satisfied by having regard to their private lives alone. We must take into account also their working conditions and the conditions under which they travel to their work. Communal feeding, and even the Ministry of Food's scheme for supplying meals in London shelters, should not be considered entirely without reference to industrial canteens, the use of mobile canteens, and the exigencies of rationing imposed from time to time by the food situation.

Such complexities as these are responsible for the strain which is being placed on administration, whether in regard to the maintenance of such public services as transport, water, gas or electricity supply, and the institution of repairs when needed, or in the extent of the resources and ability which the present local government units have at their disposal. The P E P broadsheet points to one conspicuous gap in the field of utilities, namely, the absence of organization to deal with salvage, particularly commodities, and also stresses the need for some greater sharing of disposable revenues in the London boroughs. More effective linking of regional and local executive officers is also clearly required, and there has already been a marked tendency to rely on regional administration where local administration has proved ineffective.

The broadsheet shows very clearly the impetus to regionalism which the impact of bombing on London has given, and the opportunity for general reorganization which has been provided. Continuous research into such problems might well lead to an effective combination of regionalism with democratic devolution of responsibility. Any breakdown of traditional social arrangements, notably the medical services, and the finance of local government, should lead to their radical overhaul. The decentralization of industry and public administration may have a profound effect on the future economic and social structure of Britain, while the part played by the civil population in defence of their homes and work-places expresses a conception of public service which should find a permanent place in the national life of the country.

SUICIDE OF THE HUMANITIES

To Hell with Culture

Democratic Values are New Values. By Herbert Read. (The Democratic Order, No. 4.) Pp. 64. (London: Kegan Paul and Co., Ltd., 1941.) 1*s*. net.

THIS may not seem an appropriate place to review a book in which the word science is never mentioned, and from which the very conception of scientific activity is totally absent. But, as recent correspondence in NATURE has shown, many men of science feel themselves a part of the cultural tradition of our civilization, and they cannot be expected to remain unmoved at the spectacle of so respected a critic as Mr. Read committing *hara-kiri* in the name of culture as a whole. At least they may look to their spiritual pharmacopœia to see if there is not some remedy which they can prescribe for the patient.

Mr. Read has little difficulty in demonstrating that 'culture', in the conventional sense of painting easel pictures and writing poems, is in a bad way, and has degenerated into a mere decorative veneer plastered over the realities of our daily lives. Men of science, however, will be tempted to point out that our civilization is now dependent on scientific techniques at every point, equally in the most fundamental matters such as food-raising and in the most superficial titbits such as the colours of ladies' lips, and that a culture which forgets its scientific components is obviously foredoomed to evaporate into hot air. It is perhaps because Mr. Read does uncompromisingly omit any reference to scientific thought that his suicide is so clearly 'while of unsound mind'.

He begins by defining democracy as being the realization of the three fundamental tenets of communist economics: production for use, from each according to his ability, to each according to his needs, and the ownership of industry by the workers. This may be rather like defining a rose as a heavy soil and plenty of farmyard manure; but let that pass. He proceeds to his most valuable and profound point, that a living democratic culture is an attitude of mind which permeates and fertilizes every activity of every individual; it is not a thing apart, to be tasted only on Sunday afternoon excursions to the museums, but is a flame perpetually burning in the mind. A valid culture, he says, must be there in the fingertips of a potter as he throws an ordinary beer-mug on the wheel; it is an example to catch the imagination of the Neolithic craftsman rather than of our present industrial proletariat, but the point it is making is one which must be the very basis of a modern democratic civilization.

There is here, surely, a promising line of attack on one of the problems facing men of science to-day, namely, how far they should take up definitely political or administrative work. From a long-term point of view at least, the mode of operation of a cultural activity such as science should be through its influence on the general outlook and presuppositions of the ordinary man. The social function of a good man of science is not to become a bad administrator, but to encourage and direct the scientific interests of his fellow citizens, from politicians to washerwomen.

When Mr. Read attempts to show concretely what the inspiration of culture would mean in daily life, he produces only an out-and-out functionalist theory of æsthetic value. But is this ever-present culture really no more than an attention to function? A bronze Han amphora holds no more wine, and holds it no better, than the crudest Brummagem jug. Without claiming to have any special qualifications of æsthetic training, one may wonder whether the motor-cars which Mr. Read finds so satisfactory have any more claim to beauty than a fashionable 'Vogueish' elegance. Efficiency is an ingredient in beauty, perhaps even a prerequisite for its creation. The invention of the internal combustion engine made it impossible to go on designing the most beautiful vehicles yet made by man, the Victorian hay waggons and carriages, just as the steam engine put the clipper ship into the category of an out of date *genre*. A living culture must value efficiency, which to-day means valuing science; but it is not enough to pay attention only to its sleight-of-hand trickery in getting material results.

The fundamental contribution of science to culture, and one whose neglect is most damaging to Mr. Read's argument, is the concept of workable compromise. Every scientific theory is a compromise, between those things which it fits and accounts for, and those which it does not. The attitude of the man of science to it is a compromise, a mere suspension of disbelief. His most powerful logical weapon, as Hardy has recently pointed out, is the beautiful and subtle method of *reductio ad absurdum,* in which an uncompromising logical argument is allowed to destroy itself. It is a technique of thought which cannot be avoided in any system with an empirical reference; nothing is more absurd than a perfectly logical theory which does not produce the right answers, and nothing more useless. Other cultural activities, such as painting and writing, do not suddenly find Mother Nature pouring on their heads a jug of real, and very cold, water. They can carry theories to their logical conclusions, and there is no one to laugh. In the last twenty years they have done so in almost every field. The study of formal design had already by 1918 been carried to the point where Rodchenko and Malevitch were painting white shapes on a white background; the study of pictorial association led Masson and some of the Surrealists to paint by automatic writing; and Hugo Ball and the poets of "Transition" wrote in purely nonsense syllables.

Men of science, who after all spend most of their time being incomprehensible to their fellow citizens, cannot object to incomprehensibility in the arts. But in a scientific theory the 'difficult' theoretical statement is merely an intellectual compromise with a stubborn body of facts, and is given up if it is reduced to absurdity by failure to give a tolerably complete account of them. Culture in recent times seems to have copied the boldness of science in introducing queer notions, but not the tentativeness with which science advances them. Mr. Read, in fact, adopts the fashionable view that a *reductio ad absurdum* is a good thing in itself, not a ground for rejecting a theory but a proof that the analysis has been made on the right lines and has revealed the "contradiction of opposites" which is supposed to lie at the heart of every phenomenon. This theory, which is often passed off as Marxist thinking (perhaps rightly, but that is a matter for the exegetes), is itself the exaggeration to the ultimate extreme of the valuable scientific technique of analysis in terms of competing processes. Since it postulates a conflict which cannot be reconciled within a single framework of causality, but inevitably requires a transition to a "higher synthesis", it leaves one with no guide as to what the outcome of a given situation will be, and one can name the winner with a free conscience. Mr. Read, for example, points out the conflict between utility and decoration in the design of a beautiful object, shows how the two considerations are irreconcilable in our present capitalist world, and then designates utility as the sole arbiter of taste in the future.

Again, and more importantly, he shows how the creative spirit of man is brought to naught by the restrictions of a competitive and monopolistic society; and he demonstrates how this gives rise to a rigid distinction between the artist and the workman. His solution is again a runaway win, this time for the workman. He envisages a society in which there are no specialized artists, but in which every individual realizes his full originality as an integral part of an all-embracing community; as an example he mentions the medieval guilds who built the great cathedrals, though one would have been interested to have his account of how their overwhelmingly religious preoccupations fit into his theory of the functional basis of beauty. Such a suggestion could scarcely have been the product of the compromising scientific method of thought; and it could scarcely be applied to the scientific aspects of cultural activity. Every man his own Einstein is a *reductio ad absurdum* of a slogan, if ever anything was.

The antagonism between freedom to create something new, and integration into an ordered society, shows every sign of being a permanent conflict. It can certainly not be resolved by nominating one side or the other as paramount. Men of science may perhaps be pardoned if they suggest that it is, at the present time, more satistorily dealt with in the scientific field than in any other. Science is an ordered whole, not an anarchy like literature or painting; but even its most cherished tenets can, with considerable but not undue difficulty, be upset by anyone who shows himself capable of doing so. To transfer this solution to other and more general fields of activity would be difficult, but there is no reason, in an economics of plenty, why it should be impossible. What is necessary is to ensure that a man can make enough to live on while doing something which most people believe to be mistaken, but not ridiculous; mistaken because it is new, not ridiculous because it is part of an ordered whole. A cultural activity which has solved this problem as well as science has done still has something to offer to the basic notions of civilization, and is justified in asking Mr. Read to "include me out" of his "To Hell with Culture."

C. H. WADDINGTON.

APPLICATION OF ATOMIC THEORY TO SOLIDS

The Modern Theory of Solids
By Prof. Frederick Seitz. (International Series in Physics.) Pp. xv+698. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 49*s*.

THE theory of solids is a title which might include many branches of science which are not treated in this book; for example, elasticity, plasticity and the mechanics of rigid bodies. Its subject-matter is more restricted, and can be described as the application of the discoveries of atomic physics to explain the properties of solids. Successful applications have been achieved in three main fields: magnetism, the electron theory of metals and the electrostatic theory of ionic crystals. Especially since the introduction of quantum mechanics, each of these subjects has had an important influence on the others, and this book is the first, so far as I know, to treat them all in the same volume.

In the history of modern physics, it cannot be claimed that the study of solids has led to the discovery of important new laws such as those which have been found through the investigation of gases, atomic spectra and fast particles. The properties of solids have lent important support, however, to principles discovered in other ways. For example, Einstein's discussion of specific heats was one of the earliest applications of the quantum theory to follow Planck's treatment of black body radiation, and Lorentz's derivation of the relation between electrical and thermal conductivity of metals showed the electron to be a constituent of solid conductors. More recently, Sommerfeld's discussion of the specific heats of metals and Bloch's of the conductivity at low temperatures provided substantial additions to the mass of evidence which was marshalled in support of the new quantum theory within a few years of its formulation.

It is also true that most of the research workers who are working on solids at the present time are not doing so with any hope of discovering new laws of a fundamental kind. Nobody doubts that quantum mechanics is an entirely adequate theory to cover nearly the whole field, and that, though in the future our interpretation of the symbols may possibly change, the equations of quantum mechanics are as valid to describe the processes of physics and chemistry as those of Newton to describe the behaviour of the planets. Where the quantum mechanics of to-day breaks down is, as we know, within the nucleus, and in dealing with very fast particles or with the properties of the newest particles such as neutrons and mesons. To describe the properties of atoms as they exist in solids, it should be just as successful as Newtonian mechanics is in astronomy without the refinements of relativity. There is, however, one phenomenon, of major importance, namely superconductivity which has hitherto resisted all attempts at an explanation, and it is just possible that this is due to a defect of present-day theory rather than to lack of skill on the part of the theorists. It may be that at very low temperatures some small unknown term in the interaction between electrons influences their properties in this unexpected way. But the balance of probability seems to be against this; certainly no one has been able to deduce from this phenomenon that quantum mechanics is untrue.

The study of solids can therefore only be pursued with two worthy ends in view; it can be pursued for its own sake, as an æsthetically satisfying body of knowledge, like the pure mathematics of Prof. Hardy's "Apology", or it can be undertaken because it may help the practical men who use solids. Its claims under the first head are not entirely negligible, though nothing can, of course, be claimed comparable with the exquisite rightness of Dirac's theory of the electron or with Einstein's relativity. But some elegant and beautiful work has none the less been done, especially since the introduction of quantum mechanics. I may mention in particular the theory of the motion of an electron in a periodic field, with its satisfying explanation of why some solids (for example, metals) conduct while others do not, and its rather surprising power to account for some of the queerer regularities of metallurgy, such as the Hume-Rothery rule.

As a guide and stimulus to the practical physicists and metallurgists no one will deny that the theory of solids is of value. With this end in view, it seems to me more worth while to attempt to correlate observed phenomena and to give a general explanation in terms of atomic physics, than to attempt any sort of quantitative explanation of phenomena so complicated as those that occur in solids. In the theory of metals, for example, a very simple explanation has been given by Wigner and Seitz of how metal atoms cohere, and a rough quantitative application to sodium made. Further, in a qualitative way the difference between sodium and, for example, copper or nickel can be understood. But I question the value of attempts to improve these theories quantitatively; these attempts are usually not very elegant or pleasing, and are too complicated to be helpful or suggestive to the experimental worker. In fact it seems to me that in this field a fact is only worth explaining if it can be explained simply; for example, if a phase diagram in metallurgy can be explained by Hume-Rothery's rule or some similar generalization, the explanation is worth while, but if it depends on some long calculation which balances up the energy of one phase against another, it had better remain unexplained.

My only criticism of Dr. Seitz's book is that this does not seem to be recognized; it is difficult to separate the important and suggestive theories from the superstructure that has been built on them in the attempt to get quantitative agreement with experiment. The book is very complete; the student will have no difficulty in finding out what has been done on any subject. The most detailed parts deal with Born's theory of ionic crystals, and with the basis of the modern electron theory of metals, namely, the theory of the motion of an electron in a field having the symmetry of various crystals. There are chapters or sections dealing with various special applications such as luminescence, *F*-centres, ionic conduction, phase transitions and so on. Dr. Seitz is to be congratulated on writing a book which, through its completeness and reliability, will be of very great value.

N. F. MOTT.

SCHOOL PHYSICS

(1) General Physics

By W. L. Whiteley. Pp. viii+590. (London: University Tutorial Press, Ltd., 1940.) 7*s.* 6*d.*

(2) Intermediate Practical Physics

By T. M. Yarwood. Pp. xii+308. (London: Macmillan and Co., Ltd., 1940.) 6*s.*

(1) THE aim of this book is to provide a course in general physics to the School Certificate stage which will enable pupils to build up, on an experimental basis, a knowledge of physical principles and an appreciation of their importance in daily life; and both author and publisher are to be congratulated upon the success with which this aim has been achieved.

The writer has eschewed padding in any form, but has not sacrificed interest or become dreary in the process. The writing is clear and lucid throughout, and the diagrams are ample and good; applications and illustrations are dealt with, and it is quite remarkable how much has been included in his survey.

The book is very good value; were it not for the narrow margins, and the date, one would certainly not imagine it to be a war-time production; it is a thoroughly satisfactory and competent piece of work.

(2) Mr. Yarwood has furnished sufficient material to provide either a one-year or a two-year course in practical physics, the chief aim being to deal with experiments that will help the student in his theoretical work after he has passed the School Certificate stage. In this the author may certainly be deemed successful. He says, very well, that though the student in pursuing such a course as this does not do any pioneer work, none the less the spirit of investigation should underlie the practical exercises; he assumes, very sensibly, that the student will already have had some experience of practical work; and, in a short introductory section he gives a number of useful notes on method, errors of observation, accuracy of measurements, calculation of results, and graphical work.

The experiments dealt with include nine in properties of matter, nineteen in heat, twenty-seven in light, five in sound, thirteen in magnetism, and thirty-three in electricity, and among them has been found room for the fourth power law of radiation, defects of lenses, Newton's rings, Lloyd's mirror, the frequency of the A.C. supply, and the thermal emissivity of a wire: such items add greatly to the inspirational value of the book.

The reviewer questions the soundness of the explanation of Hope's experiment, given on p. 46. Though a belt of ice will form on the inside of the can, round the middle, it is extremely doubtful if any crystals of ice actually become detached so as to be able to rise. It is more probable that cooling of the upper part is brought about by progressively advancing convection currents. There are also two or three slips which might well be rectified as soon as opportunity arises. On p. 63, for example, the first note is incorrect, as has actually been made clear eight lines above; the diagram on p. 115 is carelessly drawn, and Note 1 on p. 122 is incorrect: the critical angle for glass to air is not the one actually measured, but the angle between the normal and incident ray at the liquid-glass interface which gives rise to total reflexion at the glass-air surface: this angle, as is proved, is equal to the critical angle for light passing directly from liquid to air. These points are not of major importance, and certainly do not detract appreciably from the general merit of the book.

B. M. N.

Outlines of Structural Geology

By Dr. E. Sherbon Hills. Pp. ix+172+4 plates. (London: Methuen and Co., Ltd., 1940.) 6*s.* 6*d.*

THE author of this admirable little book tells us that his aim has been to present "a brief, yet reasonably complete and well-documented summary of structural geology, with special reference to those aspects of the subject with which the field geologist should be acquainted". Dr. Hills has been highly successful in attaining his object. The chapters deal in turn with non-diastrophic structures (for example, primary structures of sediments, effects of moving ice and subaqueous slumping); mechanical principles of rock deformation; major crustal structures; folds (geometry and description, mechanics of formation, and associated structures such as joints and cleavage); faults (nomenclature, description, and associated structures, such as slickensides and tension fractures); structures of igneous rocks (flow, fracture and tectonic relationships); and finally, petrofabric analysis.

The last two chapters, giving for the first time in an English text-book a concise and reliable account of the results of recent work in two difficult but profitable fields of research, will be particularly welcomed. Topics such as isostasy and the fundamental causes of diastrophism have been omitted, quite properly, in a book of this scope. There are, nevertheless, instructive discussions of geosynclines, nappes and other alpine structures, and rift valleys. In connexion with the last of these, one is glad to see full reference to Wayland's compression hypothesis and the support given it by Bullard's gravity measurements across the African rifts. Indeed, the book is commendably up to date throughout, and ample guidance to wider reading is provided by numerous and well-chosen references to the leading literature.

The book is copiously illustrated with very clear and well-drawn diagrams and figures, and these, together with an effective series of excellently reproduced photographs, add greatly to its educational value. Both as an introduction to the subject and as a sound and balanced review of its present status the book can be strongly recommended to students, teachers and geologists in general, by all of whom it should be highly appreciated.

Advanced Readings in Chemical and Technical German

From Practical Reference Books; with a Summary of Reading Difficulties, a Frequency Vocabulary List and Notes. Selected and edited by Prof. John Theodore Fotos and Prof. R. Norris Shreve. Pp. xliii+304. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1940.) 15*s.* net.

THE selections for translation given in this book have been chosen from seven standard works of reference in German, which cover inorganic and organic chemistry and metallurgy. No explanation is given as to why physical chemistry has been excluded, and the omission seems curious. There is an introduction giving some points of German grammar and construction which would be useful in revision. A minimum chemical German vocabulary arranged in numbered order of frequency of occurrence follows. Since physical chemistry is not represented in the book, this order is purely accidental and of no real value.

The extracts for reading follow, each with a vocabulary and notes explaining points of interest or difficulty. These extracts are full of arithmetical numbers, but no table of German equivalents of these is given, so that anyone reading "19,25°" would be likely to think of the English rather than the German words for this.

There is no doubt that this book should prove useful, although the highly condensed style of the works of reference used as sources does not provide a representative specimen of the journal literature, which is probably consulted to an even larger degree.

New Style Exercises in Biology

Part 1: Botany. By F. Whitwam Jones. Pp. 64. (London: J. M. Dent and Sons, Ltd., 1940.) 1*s.* 4*d.*

IF only for its novelty, Mr. Whitwam Jones's book is worthy of earnest consideration. It consists of a series of detachable pages containing a variety of exercises and questions which, according to the author, should help the pupil of School Certificate standard to confirm, apply and extend the knowledge which he has gained during his school training. As an interesting attempt to help pupils to attach thoughts to words, the book must be well praised. Yet one of the great dangers of instruction of this kind would appear to lie in the development of a rigid uniformity in the type of apparatus used in each school in order to make the student familiar with the "classic" experiments in vogue at the time. This would inevitably lead to a sidetracking of initiative in teaching method and to considerable restriction in improvization in the devising of experimental material, factors which are of the greatest importance in the progress of good science teaching.

The idea behind the book is laudable, but is one that would appear to bear the richest fruit only if applied by the individual teacher each year for the pupils in his or her school. A far more serious criticism is that Mr. Jones's teaching seems to be confined to biological issues in which the extreme worth of his subject in social and human relationships is completely omitted. Perhaps this omission is rectified in the second part of this book, which is yet to be published.

T. H. H.

French-English Science Dictionary

For Students in Agricultural, Biological, and Physical Sciences. By Prof. Louis DeVries, with the collaboration of Members of the Graduate Faculty. Pp. viii+546. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 24*s.* 6*d.*

THIS dictionary of 43,000 entries includes terms of agricultural, physical, chemical, geological, medical and biological interest as well as many literary terms. About five hundred idioms are also given. A list of French abbreviations and their translation into English is appended. The book should be useful to all students of science.

RESEARCH IN CANADA

By Lieut.-General A. G. L. McNaughton, C.B., C.M.G., D.S.O.

Formerly President, National Research Council of Canada; General Officer Commanding 1st Canadian Corps Overseas Forces

The National Research Council

THE organization of research in Canada as a function of government dates back to 1916, when an honorary Advisory Council for Scientific and Industrial Research was set up. It was not contemplated at that time that this Council would establish laboratories of its own; it was to act as an agency for consultation and co-ordination between those already carrying on research in the existing laboratories of the several departments of the Dominion and Provincial Governments, in the universities, and in industry.

A report prepared at the time indicates that the total annual expenditure on research in all governmental laboratories, both Dominion and Provincial, amounted to considerably less than 100,000 dollars; and that of some 2,400 leading Canadian firms engaged in manufacturing who replied to the questionnaire, only 37 had laboratories which even pretended to engage in research.

As a result of the pressure of public opinion concerning these limited facilities, the matter was repeatedly considered in Parliament, and, eventually the Research Council Act was passed in 1924.

The Council's main laboratories, situated at the junction of the Ottawa and Rideau Rivers, were commenced in 1930 and opened at the time of the Imperial Economic Conference in 1932.

By 1939 the Council's annual budget on current account was somewhat more than a million dollars. Meanwhile an even more striking increase had taken place in the facilities in Canadian industry itself, and by 1938 it is estimated that these comprised upwards of 1,000 industrial laboratories for research, testing and plant control, with some 2,500 professional workers employed full time. Similarly in the Dominion Departments of Agriculture, of Public Works, of Mines and Resources the last two decades have seen the creation of a number of research and testing laboratories related to their special functions and duties, all of which represent a very substantial asset. Elsewhere the most notable addition was the Ontario Research Foundation, which operates in the most friendly relations with the National Research Council.

In 1938 provision for a further large group of laboratories to provide the Council with additional facilities, particularly for aeronautical engineering, hydraulics and high-voltage electrical engineering, was sanctioned by the Government. Construction was started in 1939, and is now advanced to the point that in some cases the buildings are in occupation.

As a result of these measures, at the outbreak of the present War, Canada had the laboratories and trained staffs competent to act as a nucleus in undertaking the study of the problems presented in almost every field of war requirements both within the sea, land and air forces themselves and also in the industrial life of the country as it had to be re-oriented to produce the vast and complicated supplies needed in transition from a peace to a war basis.

But the adequacy of physical equipment and technical staff is only one side of the question, and what is probably equally important as an asset is the organization of the Council itself as a going concern, and the intimate relations which had been developed with every branch of science in Canada—with universities, with industry, with departments of the Dominion and Provincial Governments concerned with research problems, with the great professional societies in medicine, engineering, forestry, etc., with the Canadian Engineering Standards Association in the field of industrial standardization, and many others.

The National Research Council consists of fifteen members selected for terms of three years from among men prominent in scientific work in Canadian universities or in Canadian industry. The Council is required by statute to meet at least four times annually in Ottawa. There is a president, appointed by the Governor in Council for a term of years, who reports directly to the Privy Council Committee on Scientific and Industrial Research of which the Minister of Trade and Commerce is the chairman. The office of president is now filled by Dean C. J. Mackenzie, professor of civil engineering in the University of Saskatchewan.

Apart from administration, which is organized much on the usual lines of a department of Government, the staff of the Council is grouped in a number of divisions each under a director.

The Divisions of Physics and Electrical Engineering, Chemistry, Mechanical Engineering including Hydraulics and Aeronautics, Biology and Agriculture are responsible for the direction and

---

* Substance of a paper read before the Royal Society of Arts on May 13.

conduct of the technical work in the fields indicated by their designations. There is a Section on Research Plans and Publications concerned with the collection, collation and issue of scientific information and with the general development of co-operative investigations through committees, etc. There is also a Section on Codes and Specifications, matters which are in the highest degree important in relation to mass production in war. Provision is made for the closest co-operation and collaboration between all branches concerned in any particular problem.

One of the great advantages possessed by an organization such as the Council's own laboratories with their comprehensive representation of all branches of science is that experts in every line required can be brought together at short notice to study a problem and to work as a team for its solution. This facility is very important, for in most research problems related to industrial or agricultural production or processing we are usually confronted with limiting factors of many kinds, and it is not easy in advance to determine in which branch of science the answer should be sought. For example, in a recent study of the cold storage of chicken which had developed a defect called 'freezer burn', which spoiled the appearance and marketability of the birds, the work started in the hands of biologists and mycologists on the supposition that a fungus was involved ; then chemists were required to study the breakdown products, and in the end the answer was found to lie in the very precise control of humidity at low temperatures—a solution contributed by the physicists and engineers.

ASSOCIATE COMMITTEES AND CO-OPERATIVE RESEARCH

In order to bring to bear the knowledge of scientific men in other institutions and in industry and to correlate the work of research in all organizations concerned, a number of so-called Associate Committees have been set up. The function of these Committees is to direct co-operative research on the problems assigned to them ; to settle the objectives ; to indicate the individuals or organizations which should undertake the several component parts of the inquiry ; to receive and co-ordinate the resulting information ; and to make it available to those who will turn it to advantage.

The Council endeavours to ensure that these Committees are comprehensively representative of all interests and we expect them, each in their proper sphere, to form a national plan into which all who are in a position to contribute information can fit their own particular lines of research. The actual investigations are carried out, not only in the Council's laboratories, but also in the laboratories of the various universities, Government departments and industrial institutions throughout the country ; also much of the initiative in these Committees lies with the outstanding experts from other organizations who have associated themselves with the Council in this work.

Time does not permit me to recite to you the long list of these associate committees or to go into, in any detail, the important tasks which they are carrying out for Canada. But, in order to carry some picture of the wide range of work involved, I would, however, by way of illustration, like to mention one or two in several diverse fields.

In agriculture I would mention the Committees in charge of Grain Research and of Transport and Storage of Food ; these, both by reason of the great importance of the subjects and also on account of the very substantial results which have been achieved in comparison with the trifling expenditures of money which have been made.

The Grain Research Committee is a co-operative organization with the Department of Agriculture, on which the western grain growers, provincial agriculture departments, plant breeders, etc., are represented. It has developed new varieties of rust-resisting wheat, and these have been thoroughly tested, not only from the rust-resisting point of view, but also for their milling and baking qualities. We have every confidence in them and they have now been multiplied and the seed made available in considerable quantities for use in the areas where rust is most likely. Canada has suffered losses due to rust alone of 100,000,000 dollars in a single season. If we can take that element of hazard out of the grain-growing business it tends to put it on a better basis and gives some increased assurance to the farmer as to what he will reap when he has sown.

With Canada's mounting surpluses in wheat which she could not market in consequence of the changing policies of European countries towards self-sufficiency in growing their own grain, she has had to turn the attention of her farming committees more and more to livestock and poultry, and the work of the Committee on Transport and Storage of Food, another joint undertaking with the Department of Agriculture, has extended all the way from detailed investigations of the Canadian ports to determine plans for the cold-storage facilities needed for this trade to the conduct of a bacon survey in the United Kingdom.

In forestry, I would mention the Committee organized in co-operation with the Forest Service of the Department of Mines and Resources. This Committee has concerned itself with such matters as the study and mitigation of forest hazards, through fire, insects and other pests; with the preparation of a manual giving advice as to the management of the 'farmer's woodlot', a most important source of raw material. This manual is now in general use in the Maritime Provinces and Quebec.

Perhaps the most interesting project is concerned with tree breeding, which a few years ago would have been deemed a fantastic enterprise because of the hundreds of years which would have been required to bring into existence a new tree species and fix its characteristics; but now we have colchicine, a drug which, administered to a plant shortly after pollination, causes a very great increase in the varieties or sports to occur in the next generation, thus giving wide scope to the plant breeder for selection. Nothing occurs which would not otherwise occur naturally, but you may get, if you are fortunate, in a single small plot, in a single season, a multiplicity of varieties which otherwise would take years of patient work to collect.

Another interesting line of research which is being developed by this Committee is the vegetative reproduction of desirable species through the use of plant hormones, a number of which were first synthesized and introduced to science from the chemical laboratories of the National Research Council.

These very remarkable substances in minute, almost microscopic, doses have the property of stimulating root formation. By treatment with these hormones, cuttings of plants, which otherwise would normally not root, can often be induced to do so. One important use of this technique is in the reafforestation of areas where the trees have been destroyed by some pest like the white pine blister rust. Even in the worst areas some trees survive due to some natural inherent resistance. Cuttings from these trees are taken, treated with hormones, rooted and grown in the nurseries as planting stock. These young trees have all the natural heritable characteristics of the original tree from which they came and thus are immune to the disease in question.

I could continue with examples of the work of many other associate committees in the fields of medicine, chemistry, physics and engineering; of the detailed and exacting work carried out by joint committees with the Department of Finance in the preparation of a National Building Code for Canada which is now, despite the War, in process of publication and which should bring order into a situation which, under the conflicting jurisdictions of municipality, province and dominion had become most seriously confused to the disadvantage of the public.

I would just like to record my tribute to the co-operating institutions and to the hundreds of men and women with special scientific or industrial training and experience who, without any remuneration whatever, have associated themselves with the Council in this work and out of whose collaboration many important and useful developments have been and are being brought to a successful conclusion.

ASSISTED RESEARCHES

In order to make use of the facilities for research which exist in a number of Canadian universities and to encourage their further development, the Council in the early years of its existence instituted a system of assisted researches through which the professors in charge could be given financial assistance for the provision of needed apparatus, laboratory help and similar out-of-pocket expenses other than their own salaries.

Applications for these are most sympathetically considered; much useful work has been accomplished of value both for the new knowledge secured and, perhaps even more important, for the training given to the workers.

SCHOLARSHIPS

Another aspect of the Council's concern with the training of research workers is represented by the scholarships which each year are awarded to some seventy or more post-graduate students. These are tenable at Canadian universities or, in special cases, abroad. Through these scholarships which are being given year by year in increasing numbers, in addition to providing the needed supply of highly trained research workers, a deliberate attempt has been made to assist the building up of the post-graduate schools in the Canadian universities.

ENCOURAGEMENT OF RESEARCH IN UNIVERSITIES, ETC.

While the National Research Council has itself a number of very well-equipped laboratories in all lines, yet there has been no attempt to monopolize research; in fact, the very opposite, for it has long been realized that for the safety of the nation against peace-time industrial competition, let alone to meet the needs in war, you can never have too much research.

In Canada the difficulties are particularly acute for, as is well known, most of her principal industrial companies have affiliations with larger organizations abroad to whom there has been a natural tendency to refer any research problems that arise from time to time. It is often very difficult to examine these problems completely apart from the special environment in which they have come to attention and the solutions proposed are often, therefore, inadequate, and, both on this ground and on account of delays, very heavy losses are involved.

A more serious loss is due to the fact that without a corps of trained investigators on the spot, the needs of the situation are not fully appreciated and many opportunities for useful inventions and developments are missed or unduly delayed.

RESEARCH INFORMATION AND INTERNATIONAL AFFILIATIONS

In peace-time, in order to maintain contact with research work going on all over the world, the National Research Council maintains membership in the principal international scientific conferences and meetings, arranges for Canadian representation where required and collects in its library in Ottawa for reference, copies of all papers, proceedings and other information of importance. This is made available as desired to Canadian workers.

For many years also the Council has maintained the closest possible contacts with the Department of Scientific and Industrial Research and the British Standards Institution in Great Britain. These contacts were much strengthened and developed by the Imperial Conference of 1930 and the Imperial Scientific Conference of 1936 and again in August 1939, on the occasion of the visit to Great Britain of a representative group of Canadian manufacturers who had come to Great Britain to familiarize themselves with the needs of war-time industry so that Canadian production could be directed to those articles which would be most required and most useful.

WAR-TIME DEVELOPMENTS

So far as war-time developments are concerned, I am under the difficulty that no specific information which would be of value to the enemy can be disclosed, so I have to content myself with a few illustrative statements which must be rather general in character.

First, as regards finance, the funds placed at the disposal of the Council for the current year by votes from Parliament and grants-in-aid from the Naval, Land and Air Forces in the Department of National Defence are some fivefold greater than for the last pre-war year. In addition the Council and its technical staff will be responsible for the scientific and technical organization and advice in connexion with other projects not directly administered, which will involve about twice to three times as much again.

Further, in order to provide some measure of elasticity in the finances of the Council, a number of Canadian corporations, large and small, and private individuals have joined together to establish a trust fund of much more than a million dollars, with more available if required. The committee in charge has been enjoined by the donors to make it its business to ensure that no worthwhile project of research, related to the war effort of Canada, which is sponsored by the National Research Council, should be delayed or hampered by lack of money. In this public-spirited group the mining industries of Canada have, as usual, been conspicuous for their generous support of research. Another example of the assistance received from this source is the support given to the Canadian Corps in the organization and equipment of their tunnelling companies. One of these, as is well known, is now at Gibraltar making effective use of the modern machinery presented by the Canadian mining industry. The other Company is using similar equipment in Great Britain.

What is, in effect, a further additional expansion of the Council's activities is represented by Research Enterprises, Ltd., a wholly owned Government corporation which has been set up by the Canadian Ministry of Supply primarily to produce for the armed forces and for industry, inventions and apparatus which had been developed in the Council's laboratories. Already, optical instruments, including gun sights and range finders, radio gear and similar articles, are in production in the large new factory which has been erected, and very shortly the company will be turning out its own supplies of optical glass in quantity.

Thus a small nucleus established in the optical and radio laboratories in the years before the War has been given substance and developed into a key industry of essential importance for our war effort.

The Council's Metrology Laboratories are another example of a small but effective nucleus which has been expanded to large dimensions to care for the standardization of the vast numbers of gauges necessary in the munitions industry.

In the field of radiology, special attention has been paid in the Council's laboratories for many years to the examination of castings, particularly those in light alloys required to carry stress in aircraft construction. Working with the producers the technique of making sound castings had been developed before the War to a high degree of perfection, and the knowledge of this art is now proving of great value to the Canadian aircraft industry.

X-ray photographs up to 600 kv., which is sufficient to penetrate several inches of steel, can be taken. For greater thicknesses a plentiful supply of radium is available by reason of the fact that the bulk of the world's new supply derived from the mines at Great Bear Lake and refined by the Eldorado Company at its Port Hope plant comes to the Council for test and certification.

Turning to another of many fields, I would like to mention the very important programme which has been initiated by the Committee on Aviation Medicine under the chairmanship of the late Sir Frederick Banting. It was on the business of this Committee that Sir Frederick was proceeding to England when he lost his life in a flying accident (see NATURE of May 3, p. 535).

All this great range of work of which I have been speaking is going forward in Canada in the closest sympathy and understanding both with the authorities in Great Britain and also with our mutual friends and colleagues in the United States. In order to help in the maintenance of effective contact the British Government has established a Scientific Liaison Office with the Council in Ottawa and we have been privileged to receive first Prof. R. H. Fowler and more recently Sir Lawrence Bragg.

At the present time a number of the senior members of the National Research Council are in England to familiarize themselves with the latest methods and requirements so that work in Canada may be kept related to problems of immediate practical importance.

There is a constant flow and interchange of workers and the various problems are taken up as available facilities best indicate. Needless to say, there is no delay or reservation in making the results available for application and use.

TERCENTENARY OF NEHEMIAH GREW (1641–1712)

BY DR. AGNES ARBER

NEHEMIAH GREW will always be held in honour by botanists as the co-founder with Marcello Malpighi of the science of plant anatomy. It is true that in his ideas about plant cells he did not advance much beyond Robert Hooke, who, in 1665, figured and named these units; but, as regards knowledge of vascular structure, the position is very different. Grew and Malpighi not only initiated the study of the bundle system of the flowering plant, but also carried it to a surprisingly high level, considering that they had to start from the very foundations. Grew's first book, "The Anatomy of Vegetables Begun" (1672), contains the earliest printed illustration showing vascular bundles as seen in section under the microscope. He followed up this work in 1673 and 1675 by treatises on the detailed anatomy of roots and of stems. Finally he brought all his results together, in 1682, in a splendidly illustrated folio, "The Anatomy of Plants", which included improved second editions of his first three books, as well as much additional matter. The excellence of Grew's botanical morphology and anatomy has been recognized fully; indeed his reputation in this line is deservedly so great that it has tended to overshadow the other facets of his output. It seems worth while, therefore, in this, his tercentenary year, to direct attention to certain less specialized aspects of his scientific work.

Grew's general attitude towards biology cannot be understood unless one realizes how deeply he was committed to a mechanistic view of the universe. It seems likely that Hooke, and also Descartes, had to some extent turned his mind in this direction, though in the seventeenth century such ideas were so much in the air that it is scarcely necessary to look for specific sources. It was owing to the mechanistic viewpoint of that period, that the microscope, for example, was hailed as an instrument which was destined to clear away all inconvenient mysteries. Hooke hoped that by the help of glasses "we may perhaps be inabled to discern all the secret workings of Nature, almost in the same manner as we do those that are the productions of Art, and are manag'd by Wheels and Engines, and Springs, that were devised by humane *Wit*". Grew enlarges upon this analogy between the world and a man-made machine, and seems to find it entirely satisfying. He says that "all *Nature* is as one Great *Engine* made by and held in" the hand of God. He regards this engine as having been set in motion by the Great First Cause, to which all subsequent effects can be traced back; he considers that the original causation was all that was necessary, and that, in the normal course of events, no subsequent interference has occurred. "And as it is the watchmaker's *Art*," he says, "that the *Hand* moves regularly from hour to hour, although he put not his finger still to it: so it is the demonstration of *Divine Wisdom*, that the Parts of *Nature* are so harmoniously contrived and set together as to conspire to all kind of natural motions and effects without the extraordinary-immediate influence of the *Author* of it."

This particular philosophy led Nehemiah Grew to regard it as a pious duty to discover a mechanistic "cause" for each phenomenon; he defines "an *intelligible* account" as "such as is grounded upon the *Notions* of *Sense*, and made out *Mechanically*". This mental bias gave him an over-simplified conception of causation, and a "cause" became to him almost something tangible and visually imageable. He thought that "one property agreeing to divers Vegetables should have one cause : for although the scope and end may vary, yet the cause, as it is the cause of that property, must be one". His reasoning thus induced him to underestimate the fog of obscurity which always pervades the realm of causes, and which was even more impenetrable in those days, when biochemistry and biophysics were non-existent.

Grew was perennially sanguine, and he was apt to believe that he had succeeded in solving problems of causation before which the boldest spirits might quail even to-day. As an example we may take his answer to the question of *why* certain elements of plant tissues are elongated and cylindrical. "*Succiferous Vessels*," he says, "from their *Sal Alkali* grow in length ; for by that dimension chiefly this *Salt* always *shoots*. . . . And as by the *saline Principles* the *Vessels* are *long*, so by the *oleous* . . . they are *Cylindrical*" ; if it were not for the "oleous Principle" they would be flat or angular, "as all *saline* Shoots of themselves are, as those of *Alum*". The striking feature of this explanation is not that it happens to be in itself a failure, but that Grew at that early date should have made such a valiant effort after a causal-mechanical interpretation of form.

Grew's mechanistic theory of the universe had the very great advantage that it opened his mind to the mathematical aspects of biology. In 1620 Francis Bacon had lamented that "Nothing in Natural History is found to be . . . numbered up, nothing Weighed, nothing measured", and Nehemiah Grew, in his catalogue of the Royal Society's museum, published more than sixty years later, reiterates the same complaint ; for after noting that in his descriptions he had included the "just Measures", he adds, "Much neglected by Writers of Natural History".

Grew certainly took great trouble to give the exact dimensions of the specimens he studied, and many of the plates in this book are accompanied by a line divided into inches to show the degree of reduction of the drawings. Elsewhere he made the suggestion that the figures in herbals ought all to be "drawn by one *Scale* ; or at most, by Two ; one for *Trees* and *Shrubs* ; and another for *Herbs*". He realized that, for general descriptive purposes, words of more exact connotation than the "great" and "small", of the usage then current, were needed ; he proposed that leaves 5 in. or more in length should be called "great" ; 1–5 in., "mean" ; and 1 in. or less, "small".

When objects of very small size were in question, the biologists of the seventeenth century were faced with the difficulty of not having any adequate standards of measurement. For lack of these we find Grew using such terms of comparison as "about $\frac{1}{5}$th part as big as a *Cheese-Mite*", or "the breadth of a *Marsh-mallow-Seed* or little Spangle". From a twentieth-century point of view, units of this kind may seem wholly unscientific, but when people are forced to use them, in the absence of a more advanced technique, a certain degree of accuracy can be achieved. We may recall that, when the original pennyweight was defined in terms of grains of wheat, an effort was made to secure uniformity in the grains. A grain of sand, again, sounds to us now far too indefinite to be treated as a standard but Dobell has shown that Grew's contemporary, Leeuwenhoek, had in mind a grain of about $\frac{1}{100}$ in. in diameter, when he spoke of a "fine sandgrain", while a "coarse" grain was about $\frac{1}{30}$ in. In the case of objects seen through the microscope, the difficulty of size-recording was even greater. Grew observed, for example, that the vessels of roots showed a range of about twenty degrees in size, but he had no means of assessing these degrees individually, and all he could say was that "Some [vessels] in the *Vine*, being of the greatest Size ; appearing through a good *Glass*, at least one third of an Inch in Diametre". Grew indeed even resorts to the still more unsatisfactory expedient of naming some object the size of which was recalled by the size of the image as he saw it in its magnified form. For example, he describes the spore-case of the hart's-tongue fern, when seen through "a good *Glass*", as being "about the bigness of a Cherry-stone".

Grew not only tried to give measurements for the objects he describes, but he also recognized that "The *Arithmetick* of *Nature* is every where suitable to Her Geometry", and that the parts of the plant are "as punctually, for their Place and Number, composed together ; as all the mathematical Lines of a Flower or Face". Inspired by such ideas, he made an attempt to work out a mathematical description of leaf shape, on the theory that "all Regular *Leaves*, are defined or measured out by *Circles* ; that is, by the *Arches* or *Segments* of several *Circles*". He thought that the length of the leaf was "the *Standard Measure* for the *Diameters* of these *Circles* ; these being either its full length, or certain equal parts subtracted, or multiplied". As, on the showing of his own figures, it required seven circles to define the simple leaf shape of the Cornelian cherry (*Cornus mas* L.), and as, even then, a large part of the outline failed to coincide with any of the circles, the whole scheme obviously broke down as soon as it was applied. Grew, however, was undoubtedly on the right lines in seeking for a mathematical expression for a physical phenomenon. He could not know that science was not yet in a position to help him towards answers to the questions set by his fertile and indefatigable mind. He was better served by current mathematical ideas when he came to realize that the permutations and combinations of a few characters might open up a range of differences comparable with the great "Variety, a few *Bells*, in the ringing of Changes, will produce". In discussing the tastes of plants, to which great attention was then paid as affording clues to their medicinal virtues, he gave a table showing how many threefold tastes would arise by the combination of ten simple flavours, each of which might be present in at least five distinguishable degrees of strength. He calculates that this would lead altogether to 1800 "sensible and defineable *Variations* of *Taste*".

Grew's appreciation of the importance of the virtues of herbs, with which as a physician he was much concerned, led him on to chemistry. With the aid of an apothecary whom he employed, he did a good many detailed quantitative experiments, setting before himself clear and specific aims. As an example we may cite a single one from among the problems which he tackled; he asks "whether any Plant growing in a Garden or the Field, doth not yield a lesser quantity of Lixivial Salt than another of the same kindred growing on the Sea-Coast; and with what difference?" To answer this question he "took *Garden* and *Sea-Scurvygrass*, of each lb. 1", and found that the former yielded "2 *Drachms* and 1 *Scruple*; the latter, being well washed, 9 *Drachms*, which is more than 4 times as much".

His view of the world as a mechanism not only inclined Grew to mathematical interpretations, but it also led directly to his wholehearted adoption of the atomic theory. He uses the word "principles" as synonymous with "atoms", which he regards as being indivisible, immutable, and of divers kinds. He says that "in the self same analogous way, as the *Letters* of the *Alphabet*, are the *Principles* of *Words*; so *Principles*, are the *Alphabet* of *Things*". He draws the logical conclusion that, if such unchangeable atoms are the structural basis of the world, "the *Formation* and *Transformation* of all Bodies, can be nothing else, but the *Mixture* of Bodies".

Whenever Grew grasped an idea, he did not let it go until he had wrung from it everything that, for him, it contained. The idea of atomicity, and the consequent significance of mixture, led him to certain conclusions which bore no fruit at the time, but which foreshadowed developments in science which did not actually come into being until the nineteenth century. One of these developments was the production of organic compounds in the laboratory: "Art it self", he says, "may go far in doing what *Nature* doth. And who can say, how far? For we have nothing to *Make*; but only to *mix* those *Materials*, which are already *made* to our hands. Even *Nature* her self, . . . *Maketh* nothing *new*; but only *mixeth* all things. So far, therefore, as we can govern *Mixture*, we may do what *Nature* doth." In another passage he is more specific about this hope: "we may be taught to *Imitate* the *Productions* of . . . *Vegetables*, . . . *Mucilage*, *Rosin*, *Gum*. . . . I do not say I can do all this: yet if, upon good *Premisses*, we can conclude this possible to be done; it is one step to the doing of it."

Another corollary, which Grew derived from his notions about atomicity and mixture, was concerned with the sexual process. Though he had never heard of a nucleus, and could not have had any conception of the actual nature of fertilization, he anticipated on general grounds the independence of the parental contributions in the fertilized egg. He emphasizes that "the most *perfect Mixture* of Bodies, can go no higher than *Contact*. For all *Principles* [that is, atoms] are *unalterable*; and all *Matter* is *impenetrable*. . . . In the most *visible*, and *laxe Mixture*, there is *Contact*; and in the most *subtile* and *perfect*, as in *Generation* it self, there is *nothing more*."

Nehemiah Grew's philosophy is sometimes dismissed as though it were merely second-hand Cartesianism; but though he was influenced by Descartes to some extent, it is doubtful if this influence went at all deep. It is significant that he parted company with Descartes altogether on the question of the structure of the universe. He was, as we have just seen, a confirmed atomist, whereas Descartes held the view that atoms do not exist.

Grew's whole personality seems to have been so closely integrated that his biological work, and his attitude to philosophical problems, were inseparably knit together. Great as were his specific contributions to the knowledge of plant structure, we are at least as much in his debt for his analysis of the relation between thought and observation, and for his recognition that the divorce of the two is fatal to scientific work. In his own words: "Thoughts cannot work upon nothing, no more than hands; he that will build an house, must provide Materials. And on the contrary, the Materials will never become an house, unless by certain Rules he joyn them all together. So it is not simply the knowledge of many things, but a multifarious copulation of them in the mind, that becomes prolifick of further knowledge."

OBITUARIES

Sir James Frazer, O.M., F.B.A., F.R.S.

WITH deep regret we record the death of Sir James Frazer, of world-wide fame as the author of "The Golden Bough" and many other studies of primitive beliefs and institutions, which took place at Cambridge on May 7 at the age of eighty-seven years. Lady Frazer died within a few hours of her husband.

James George Frazer was born in Glasgow on January 1, 1854. After graduating at the University of Glasgow, he proceeded to Trinity College, Cambridge, of which he became a scholar, and after being second classic in 1878, was elected a fellow in 1879. He was called to the Bar as a member of the Middle Temple, of which he became an honorary bencher in 1931.

Although Frazer's work in the early years of his tenure of his Trinity fellowship continued to be devoted to the classics—his earliest publication dealt with the Catiline Conspiracy, and he produced an edition of Sallust—his thoughts were already turning in another direction—towards the subject which was to become his main life work, the study of primitive religion. This was due in part to the influence of E. B. Tylor, whose "Primitive Culture" opened up to him vistas of investigation into the workings of the human mind still unexplored, and in part to his friendship with Robertson Smith. It was at the invitation of the latter, when editing the ninth edition of the "Encyclopædia Britannica", that Frazer contributed to that publication the articles on "Totemism" (1885) which afterwards was enlarged to appear in book form as his first separate publication in anthropology (1887). It was also the nucleus from which was developed the comprehensive and world-wide survey of totemism which appeared in four volumes in 1910 under the title "Totemism and Exogamy".

Even before this book appeared in 1887, anthropologists had recognized the appearance among them of a research worker whose investigations might well go far in the advancement of their science. In a discussion which followed the reading of a communication on burial customs by Frazer before the Anthropological Institute and published in the *Journal* of that body (1885), Tylor spoke in high terms of his work and his use of the comparative method in bringing the customs and rituals of classical antiquity into relation with those of primitive and savage peoples. This early paper by Frazer on burial customs will always have significance for the student of his work, for in it will be found the germs of ideas which he developed farther and expanded in subsequent studies. It was evident that he was then formulating the evolutionary concept which underlay his use of the comparative method in dealing with that vast store of evidence which he drew from every available source, whether in the literature of ancient and modern times, or from the researches of anthropological workers in the field, such as John Roscoe of Uganda, Sir Baldwin Spencer or C. G. Seligman, with whom he was in constant touch.

In any attempt to estimate the value and abiding quality of Frazer's work it is important to remember that he himself had in view the aim of building up by his work as a whole a vast picture of the gradual development of the human mind constructed from the interpretation of primitive thought and its survivals, which through the conservatism, the ignorance and the superstition of the unprogressive, had hampered human progress. This conception of the scope and purpose of his work was explicitly set forth in a course of lectures delivered in later years ("Garnered Sheaves", 1931) in which a parallel was drawn between the physical and the mental evolution of mankind. In his pursuit of this objective Frazer gained strength from his ability to view religious beliefs and systems objectively and with detachment. In this he came near the philosophic thought of France, for which he had a profound admiration, as was shown in his Zaharof Lecture on Condorcet delivered at Oxford in 1933. It was, however, Renan with whom was his closest affinity. Not only did he deliver a magnificent address upon Renan before the Société Renan in 1920, but he also gave the address on that thinker before the President of the Republic and the chief notabilities of academic France in 1923 on the occasion of the Renan centenary.

To trace the formative influences which contributed to the development of the mental 'make-up' of one who has, justly, been regarded as one of the greatest intellects of his generation is of more than of ephemeral interest. Indeed, it is owing to failure to grasp the part played by the evolutionary doctrine in the development of Frazer's thought and the full implication of his point of view as a whole, which renders much of the criticism levelled at his work, more especially that his evidence is divorced from its context, wide of the mark.

The first edition of "The Golden Bough" appeared in two volumes in 1890, a second edition in 1900, and after the appearance of revised versions of the several parts from 1905 onward, the third definitive edition in twelve volumes was completed in 1914. Additional matter and further evidence was included in "Aftermath" (1936). Frazer's method of working was to make an exhaustive collection of evidence bearing upon the items in hand, each item being copied into note-books under classified headings. To these entries he added from time to time as new evidence accrued. This practice he continued until nearly the end. After his eyesight failed him in his eightieth year, he, who had always written his books with his own hand, was compelled to make use of the services of an amanuensis. The accumulation of fresh material in this way necessitated in Frazer's view the periodical issue of new, enlarged and revised editions of his major works.

It was one of Frazer's most salient characteristics and a mark of his greatness of mind, that in the true spirit of the exact scientific research worker, he never hesitated to abandon a theory or hypothesis which further evidence showed to be doubtful or untenable. His theories of totemism underwent such revision no less than three times.

The publication of "The Golden Bough" established firmly Frazer's reputation as an anthropologist. He then turned to the completion of his translation and topographical study of "Pausanias", which appeared in 1898. This work necessitated several journeys to Greece, when he became a member of the British School of Archæology in Athens, and gathered material for many an eloquent passage of scenic description in his studies of the religions of the Near East. Further classical studies were a translation of "Apollodorus" (1920) for the Loeb Classics and an edition of the "Fasti" of Ovid in five volumes (1929), in which Roman belief and ritual were illuminated by a wealth of anthropological comparison. In the early 'nineties Frazer was also engaged in making the selection for his "Passages from the Bible chosen for their literary Beauty and Interest" (1895). It was characteristic of his thoroughness that before a second edition appeared in 1909, for the purposes of this and his studies of Eastern religion he had been at pains to acquire a mastery of the Hebrew language. These and other kindred studies served as a preparation for "The Folklore of the Old Testament" (3 vols., 1918).

In 1907 Frazer was appointed professor of social anthropology in the University of Liverpool, a chair which he continued to hold until 1919. Long before the latter year, honours had begun to crowd upon him all unsought, for no great scholar has ever been more modest in regard to his achievements than Frazer. Universities both in Great Britain and on the Continent conferred honorary degrees upon him; in 1914 he received the honour of knighthood; he was elected a fellow of the Royal Society in 1920, and in 1925 the Order of Merit was bestowed upon him. He was also a Commander of the Legion of Honour and of the Order of Leopold of Belgium.

In the years that followed the War of 1914–18, Frazer's activity was ceaseless and indefatigable and so continued almost up to the very end. Studies on his customary comprehensive scale on such topics as the belief in immortality (based upon his Gifford lectures of 1911), the origin of fire, and the like, were major occupations, which did not preclude the preparation and delivery of numerous lectures and addresses, and the revision and issue of several volumes of collected papers. An untiring industry crowded into a few years what for the ordinary worker would have served for a lifetime.

In 1896 Frazer married Mrs. Lilly Grove, a Frenchwoman, and herself an author of versatility and charm. Not only did she do much to spread a knowledge of her husband's work among the general public by preparing abridged editions of "The Golden Bough" and other books, as well as translating or supervising the translation of several of them into French, but also by her constant care for his health and well-being she did a great service to the science of anthropology.

Encyclopædic is the only word applicable to the work of Sir James Frazer, whether one has regard to its range or to its sheer amount. It is paying him the highest of compliments to say that among British anthropologists he ranks next to Tylor. Now Tylor, apart from the unfair advantage of having come first, founded his new science on broader foundations, approaching the subject of man biologically, so that his development in respect to body and mind alike must be studied in its entirety. Even so, he had most to say about man's most peculiar attribute, his culture, both material and moral, as it is embodied in a social tradition; while he duly noted that primitive culture somehow came to a head in a body of notions or superstitions more allied to religion than to science as we know them now. Tylor proceeded to explain—one might almost say, explain away—this ancestral tendency to invoke supra-sensible aids, as applied to the management of mundane affairs, in ways that in the main attributed reasonable, if mistaken, trains of thought to the "primitive philosopher"; he saw ghosts, hence his animism; he made gifts to them, hence sacrifice, and so on. One felt that half-an-hour's chat with a modern man of science might have rationalized human progress from the very start. But the Frazerian as contrasted with the Tylorian "savage" is a lunatic at large, who yet found his lunacy pay, in the supreme sense that nothing pays so well as survival.

"The Golden Bough" introduces us to a topsy-turvy world, in which life's chief values as we civilized folk assess them have to be turned upside down before they make sense for intelligent and successful persons having to wrestle with stone-age conditions. Just then, too, Baldwin Spencer reported from Australia intimate conversations with primitive philosophers, not imaginary but existing in the flesh, who were miserably off in all material respects, and yet spiritually got an immense satisfaction out of life by communing with things to which our science denies all objective existence.

Frazer's account of this preoccupation with a sort of dream-world on the part of pre-civilized peoples engaged in a life-or-death struggle with untamed Nature brings home to all the paradox of this law of indirection governing the human effort to live on and live well, and is his main contribution to anthropological theory. His wonderful style helped, but of far more help is the prodigious wealth of well-authenticated facts at his disposal. Indeed, he theorized half-heartedly, trusting rather to the wholesale thrust of the evidence in a direction which never varies. There is no attempt to edify. If anything, he was a rationalist, impatient of all this leaning towards the fantastic—which is the imaginative or the imaginary as you please—on which our race has hitherto been prone to rely. But he had the respect of the true man of science for his data. If this truly was so, then no less truly that is the queer kind of animal to which we belong.

This tremendous apparatus of empirical evidence will be Frazer's lasting monument. Accumulative, perhaps, in the first instance rather than constructive, yet in its whole result it is creative work of the superbest magnitude. That man's visions afford the leading clue to his cultural evolution could only be demonstrated massively, and he has done it.

R. R. Marett.

When studying at Glasgow, Frazer owed much to George Ramsay in classical scholarship, and to John Veitch in philosophy; and to both a literary training and finished style which partly explains the wide popularity of his very learned writings. From Kelvin he derived a conception of natural law, which dominated his anthropological thought. His first contribution to learning, after a revision of Long's "Sallust" (1884), was an encyclopædic commentary on "Pausanias", for which he had prepared himself by diligent travel in Greece, and intimate acquaintance with the by-ways of Greek myth and cult. This appeared in six volumes in 1898; Frazer was never brief, and he recurred to classical study in five volumes on "The Fasti of Ovid" in 1929.

Meanwhile, James Ward introduced Frazer to Tylor's "Primitive Culture", and Robertson Smith asked him to write on "Taboo" and "Totemism" for the "Encyclopædia Britannica" (1885); these articles were extended and published separately in "Totemism" (1887). Robertson Smith's own "Kinship and Marriage in Early Arabia" (1885) and "Religion of the Semites" (1889) show how much each writer owed to the other. Other powerful influences were W. Mannhardt's researches in European folk-lore, especially the cults of trees and cereals, and G. A. Wilken of Leyden, whose book on "Animism" in the Dutch Indies appeared in 1885. So, in 1890, blossomed the first "Golden Bough" in two volumes, growing to three in 1900, and to eleven in 1911 by elaboration of its chapters into treatises such as "Adonis, Attis, and Osiris" (1906), in many ways his best book, and certainly the best written. Later writings followed the same technique; from a branching tree "The Golden Bough" became a grove; "The Belief in Immortality" (3 vols., 1913–24), "The Worship of Nature" (1926), and "The Fear of the Dead" (2 vols., 1933–34) are mighty saplings.

This method of exposition enabled Frazer to incorporate voluminous information and fresh commentary in a cumulative body of doctrine. If his initial contribution to theory had not been substantial, or had he modified it greatly, it could scarcely have served him so well.

Frazer was an untiring compiler and a master of classification, and his marriage with Mrs. Lilly Grove, of French family and linguistic ability, brought him life-long, devoted and congenial help, introduced him to a wide circle abroad, and did much to popularize his work at home. From 1907 until 1919 he held a titular chair of anthropology in the University of Liverpool, where his eloquent inaugural, a plea for the preservation of the heathen, caused some heart-searching; as did his abrupt refusal to lead an anthropological expedition to Australia, "for I have never met a savage in my life". But most of his working life hovered between Cambridge and London.

More philosophical than most of his writings, and less meticulously documented, is "Psyche's Task" (1909; 1913), a "discourse concerning the influence of superstition on the growth of institutions"; while "Folklore in the Old Testament" and the "Fasti" already mentioned are essentially books of reference like the "Pausanias". In Dr. Bestermann's bibliography of eighty-four pages (1934) titles referring to Plato, Addison, Cowper, Sir Roger de Coverley, Condorcet and Renan attest wide literary interests and a facile pen. Failure of eyesight did not abate Frazer's industry or enthusiasm; but he printed little after 1934.

J. L. Myres.

Sir James Frazer was the personification of quiet industrious scholarship, very little moved by the vast accumulation of honours which came to him, and sometimes almost bewildered by publicity. His interest in religious matters was a key to a good deal in his character and work. Having begun by expounding classical culture as a growth and expansion from prehistoric germs, he was deeply and reverently imbued with the idea of evolution in religion in general. The fact that so many religions in such diverse ways express a consciousness of sin seemed to him an important factor in the interpretation of religion in general. At the same time a good deal of his critical influence arose from his appreciation of the fact that stories of virgin birth, resurrection and other ideas of the kind belonged to many religions and expressed provisional ideas rather than authoritative dogmas to be permanently associated with any one religion.

He often explained that he was essentially the disciple of Robertson Smith, whose "Religion of the Semites" stands out as one of the landmarks of the advance of thought in this field. His laboriousness was linked with a literary power of a high order and a purity of thought which made him a unique and somewhat detached figure in our time. He might be described as a man who extended Darwin's fundamental thought into the field of religious belief and practice, and his influence here is likely to be cumulative as the years pass. Particular conclusions that he may have reached from time to time were changed as he gained more light, and they will no doubt be further changed. His work may thus be built over, but it is Robertson Smith and Frazer who have in a very special degree charted the way to a new and naturalistic approach that must change many things in current thought and belief.

H. J. Fleure.

When Sir James Frazer's coffin rested in Trinity College Chapel on May 14, it was most fittingly graced with a bough of mistletoe. For if of Sir James's three hundred or so publications "The Golden Bough" alone had survived, his fame would be only a little less than it is, and were "Totemism and Exogamy" added to that, all the rest could make it but a little greater. Although we should miss the charm and humour of his purely literary works, his reputation as a man of letters would be as fully established by, say, the opening pages of "The Golden Bough" as his fame as a scholar is attested by the volumes that follow them. Frazer, though always a man of letters, and one who has adorned the literature of his country with many passages of surprising beauty, was primarily a scholar, and his great service to posterity has been in collecting and collating, with a steadfast industry that defied both flagging health and failed eyesight, a compilation, a series of compilations rather, of comparative custom and belief for the whole of the barbaric world, ancient and modern alike.

Inspired as he was by Tylor, Spencer and Robertson Smith, Frazer was inclined himself to the evolutionary hypothesis that mankind was ever groping out of darkness into light, everywhere evolving from ignorance through experience to completer knowledge, a process which inevitably produced similar phenomena at comparable stages. Although he frequently analysed the grounds of these phenomena with great acumen, he was always most careful to avoid dogmatizing, and, as one might expect in a truly great man, his modesty was as striking as his scholarship was profound. Indeed, he said himself that if his work were to live after him, posterity would doubtless value it more for its wealth of recorded fact than for any interpretations he might draw therefrom. The truth is that his comparative work has been so extensive that it has left little to be done in that particular field, and anthropologists of a subsequent generation have taken its results for granted without always realizing their debt to the work which has cleared the way for the development of their science in many new directions. Anatole France well said of Frazer that he had given the world a vast new knowledge of the mind of man.

J. H. HUTTON.

Prof. C. G. Cullis

RESPECTED by all who knew him, held in affection by his former colleagues, and revered by generations of students, Prof. C. Gilbert Cullis, emeritus professor of mining geology in the University of London, died at Hindhead on April 27 at the age of seventy.

He had been a member of the staff of the Royal School of Mines and the Imperial College of Science and Technology for forty-five years, and on his retirement in 1936 had completed nearly a quarter of a century as professor, from 1914 until 1929 as professor of economic mineralogy and from 1930 until 1936 under the more descriptive title of professor of mining geology. With Prof. W. W. Watts as geologist, and Prof. Cullis as mining geologist, the training of students at South Kensington became world-famous.

Cullis was the first professor appointed by the University of London in a subject which had its birth in the growing need for the application of geological knowledge to the investigation of mineral resources, especially at depths greater than had formerly been worked. He realized early and fully that accumulated experience in the field, not spectacular intuition, was the best guide to sound judgment concerning ore deposits, and he made himself familiar with many mining fields in Europe. He established a great reputation, and leading British mining companies frequently sought and highly valued his advice. It was largely due to his influence that these companies and Colonial Governments initiated the practice, now well established, of appointing mining geologists on their staffs, and students trained by him were in strong demand. Thus he made a solid contribution to the advancement of the industrial application of scientific knowledge and much of the progress of modern British metalliferous mining is in large measure due to the success of his former students, many of whom now occupy foremost positions in the mining and geological world.

His chief publications were: "Report on the World's Production of Silver for Indian Currency". (1919), "Report on the Copper Deposits of Cyprus", for the Colonial Office (1922), and the "Geology and Mineral Resources of Cyprus" (1924). Valuable as are these clear, concise and erudite reports, his chosen task was the training and encouragement of his students. Gifted with a prodigious memory which enabled him to acquire an encyclopædic knowledge of the world's mineral deposits, with great command of language, clear diction, capacity for taking infinite pains, and with a delightful personality, he was acknowledged to be one of the most successful teachers of his day. His past students never failed to pay tribute to their inspiring mentor, and on his retirement hundreds of them, resident in almost every country in the world, took the opportunity of contributing to his presentation fund. It was characteristic of him to give the fund for the establishment of an annual student's prize, now known as the Cullis Prize.

Cullis was for many years a member of Council of the Geological Society and of the Institution of Mining and Metallurgy, and the two bodies bestowed upon him some of their highest awards. He was president of the Institution of Mining and Metallurgy for 1937–38. More, however, than all distinctions, his supreme interest was in the performance of his daily work, which he interpreted as giving his best to his students and his colleagues.

W. R. JONES.

WE regret to announce the following deaths:

Mrs. Beatrice Bateson, widow of Dr. William Bateson, F.R.S., on April 13.

Prof. Edmond Leplae, professor of agriculture in the University of Louvain and director-general at the Belgian Ministry for the Colonies, on February 2.

Sir D'Arcy Power, K.B.E., the well-known medical historian, consulting surgeon and archivist to St. Bartholomew's Hospital, on May 18, aged eighty-five.

The Earl of Suffolk and Berkshire, who was liaison officer for the scientific department in France of the Ministry of Supply, until the collapse of France, by enemy action, aged thirty-five.

NEWS AND VIEWS

Hanbury Medallist of the Pharmaceutical Society

At the May meeting of the Council of the Pharmaceutical Society the secretary reported that the adjudicators of the Hanbury Medal have decided to make the award to Dr. Harold King, F.R.S., of the National Institute for Medical Research. Dr. King, has been engaged in research on drugs since 1913, and apart from important work on synthetic arsenical preparations, has made outstanding contributions to the chemistry of alkaloids and sterols. Of his work on alkaloids special mention may be made of that on the constitution of hyoscine, the stereochemistry of the cinchona alkaloids and the exhaustive investigation of the sources, nature and constitution of the alkaloids present in the various kinds of curare and in the plants known or surmised to be used in the preparation of that drug. In 1932, in association with Rosenheim, Dr. King suggested a new structure for the cholane ring system which is now generally accepted as a basis for the representation of a number of physiologically active substances, such as the œstrogenic hormones, carcinogenic hydrocarbons and cardiac glucosides. The Hanbury Medal, a memorial to Daniel Hanbury, who died in 1875, is awarded periodically for "high excellence in the prosecution or promotion of original research in the natural history and chemistry of drugs". The adjudication committee comprises the presidents for the time being of the Chemical, Linnean and Pharmaceutical Societies, the chairman of the British Pharmaceutical Conference and one pharmaceutical chemist.

Royal College of Surgeons: Air Raid Damage

Considerable damage has been done to the Royal College of Surgeons in recent air raids. According to *The Times* "irreparable losses, including most of the Hunterian Collection, were suffered. Incendiary bombs first fell on the roof of the building, but just as a watcher was giving the alarm a high-explosive missile struck the museum. In spite of great damage to the interior the fabric of the College is more or less intact, but the museum buildings have suffered severely. The most valuable specimens in Dr. John Hunter's collection, purchased by the Government for £15,000 two years after his death in 1793 and presented to the College, are probably safe under the debris, having previously been moved into reinforced sections of the sub-basement. The collection of portraits and pictures, including Reynolds's portrait of Hunter, are safe in the country, and the part of the records still at the College had been stored in strong rooms that withstood the blast and flames.

Thousands of museum pieces are gone, among them the skeletons of kangaroos brought by Captain Cook from Australia, and the comparative osteology collection of four thousand specimens acknowledged to be the finest in the world. Much of the material ante-dated British Museum specimens. All Dr. Hunter's eighteenth-century furniture, which was in the president's room, was destroyed. The original surgical instruments used by Lister were recovered, but many others were lost. Though the oldest mummy in the world, that of Ra Nefer, an Egyptian nobleman who died, it is said, about 2900 B.C., was destroyed, many mummies of popular interest have been salved. The invaluable Army Medical War Collection, containing plaster casts of every type of wound, was also destroyed, as were the council room and lecture theatre.

Science and Society

An address entitled "The Social Message of Science" was delivered by Prof. M. Polanyi at the University of Leeds on January 27. Prof. Polanyi in Nature of January 25, p. 119, expounded at length views which he summarized in part. He sees clearly enough what is involved in the present struggle: scientific workers must participate to defend the independence of science and all the conditions of that independence, the whole conception of culture, of law and of the purpose of society which can assure such independence. He recognizes, too, the concern of science with the entire order of society, political and economic, which affects its independence and the contribution which science can offer to the re-civilization of the world, through the example of the creative freedom sheltered by its severe professional discipline or by stimulating severity against mental sloth and deceitful argument, thus releasing a stream of creative forces. But while Prof. Polanyi holds that science has a social message, he is obsessed with the independence of science itself, and his rejection of all ideas of central planning of science and other human activities does not lead to the offer of any constructive alternative to the anarchy into which the failure to plan or co-ordinate scientific advance has led us. This obsession leads him to confuse all who attempt the central planning of intellectual activity with those who deny the existence of pure science. There are, however, many opponents of the totalitarian doctrines who none the less question the validity of distinguishing sharply between pure and applied science, but would subscribe to Prof. Polanyi's characterization of science itself as pursued in adherence to an established tradition of its own, which guides the methods of observation and the principles for analysing and organizing the accumulated data.

Prof. Polanyi's attempt to drive a wedge between the academic man of science and the scientific worker in industry is no service to science, above all when the utmost united effort is called for in the defence of freedom of thought and investigation. Much, indeed, of his analysis of the nature of science is as true of the scientific worker in industry as of his colleague in a university. The same process of organic growth can be found in both places—and, what Prof. Polanyi overlooks, the same narrow specialization, hampering scientific advance and creative work. He does indeed admit that public interest can influence broadly the lines of scientific investigation, but he passes over the value of the reciprocal influence on both science and society of accurate and forceful scientific exposition, as well as the extent to which the resources already at the disposal of science are determined by the nature of the society in which the man of science lives and its outlook on world affairs. Prof. Polanyi is accordingly largely 'tilting at windmills' in his attack on the idea of central planning. He offers no alternative to the present chaos into which the absence of plans has led us, and ignores the contribution which skilful exposition might make to the engendering of a scientific outlook in society as a whole. Much of the value of his address is lost through its attack on those who are every bit as determined as he is to defend the integrity of scientific thought and method, but who would seek to extend the realm into which that method and outlook are brought to play. Leadership, as he observes, can be retained only by those who can point the way toward the future; but Prof. Polanyi fails to do so or to see the real meaning of his own description of the stream of thought ever widening through the centuries, following steadily the purpose set by the tradition of science and its view of the purpose and true greatness of human society.

Manufacture of Magnesium

It is common knowledge that sea-water contains common salt and small quantities of other substances and even traces of rarer elements such as gold. Throughout the ages, in warm countries, a crude sale has been made by the evaporation of brine ponds with the heat of the sun, but only recently has the sea become a commercial source of two other constituents, bromine and magnesium, for which the industrial demand has grown to be considerable. The demand for bromine arose as the result of the discovery of the value of 'Ethyl' as an antiknock agent to be used with petrol: its manufacture and use has grown to a point where very large quantities of bromine are necessary. The problem was solved when the Dow Chemical Company in the United States established an elaborate process, which is largely automatic and continuous in its operation, for dealing with immense quantities of sea-water. The bromine is driven out of the water by a slight excess of chlorine and ultimately isolated. The solution is one of the triumphs of modern chemical engineering.

There is now a demand for magnesium, lightest of the structural metals. Sea-water contains 0·1 per cent of magnesium, which is separated as the insoluble hydroxide by reaction with lime produced from nearby beds of oyster shell and afterwards converted into chloride, from which the metal is finally made by electrolysis. The quantity of water treated is so large that it cannot be put back into the sea at the intake point, but must be taken by canal several miles down the coast so as to prevent dilution of the incoming water. An output of 15,000 tons of metal per annum is aimed at. The need for magnesium in quantity has become so urgent that several plants for the purpose are being erected in the United States. Some of these are based on an electro-thermal process involving the reduction of a suitable magnesium ore. The metal has such a high affinity for oxygen that at intermediate temperatures it is able to take this away from carbon oxides; to prevent this happening, the mixture has to be shock-cooled with large volumes of hydrogen. The process is a daring one, and various production difficulties are likely to be encountered; the fact that it is being undertaken shows the high level to which modern chemical and metallurgical engineering has attained. In this instance ore and electrical power are cheap; it is the process which presents difficulties.

Learning and Physique

Of one hundred and fifty members of the U.S. National Academy of Sciences examined by Dr. Aleš Hrdlička, there were "no true reds" (*Mem. Nat. Acad. Sci.*, 23, Third Mem.: Observations on the Members of the National Academy of Sciences. Washington: Government Publications Office. 30 cents). Moreover, there were no "pronounced blonds". Apparently, the members of the Academy were significantly darker in hair coloration than were the typical "Old Americans" previously examined by Hrdlička. The mean age of those upon whom the investigation was carried out was 59·57 years, which is very nearly the mean age of the total membership of the Academy. The hundred and fifty members were taller and heavier than the general run of the Old Americans. They had larger and broader heads and deeper chests than the more cultured classes of the Old Americans who are not members. Hrdlička's summary of the characters of members of the Academy is that: "They obviously present, in general, an above-the-average selection of men both as to nature and nurture. . . . They are furthermore a remarkably normal group, of evidently good heredity and good ontogenetic history". Contrary to the popular conception of what a 'professor' should be, there were no "physically abnormal geniuses in the lot", and all had good eyesight, despite the fact that many wore glasses for reading.

Perhaps most people in picturing the collective membership of any learned society would be inclined to include a very definite admixture of freaks. Such a picture of the members of the National Academy of Sciences would obviously be incorrect. Would it be incorrect for the membership of the Royal Society? Are the members of the learned societies of all countries men of above the average of physical well-being? Perhaps, after all, the old maxim of "*mens sana in corpore sano*" is correct, and the stage professor no more represents a reality than does the stage American.

Telephones in Canada

Canada now probably takes the lead of every country in the world in the number of completed telephone calls a head, and considering the total number of telephones in use, it ranks fifth (*Electrician*, April 25). The total number of telephones in Canada showed an increase of about three per cent above 1939. In that year approximately 68 per cent of all instruments were residence telephones; 30 per cent were business and residence telephones on individual lines; while two-party lines accounted for 2 per cent. Nearly half of the telephones in operation in Canada in that year were on automatic switchboards, while during the year some 50,000 telephones were transferred from manual to automatic operation. In 1939, Canada had 12·35 telephones per 100 population as compared with 12·13 in 1938. In 1938 Canada was surpassed only by the United States with 15·37, Sweden with 12·73 and New Zealand 12·69 telephones per 100 population.

The number of telephones on automatic switchboards in Canada increased from 639,700 in 1938 to 690,201 in 1939, while the number of manual switchboards declined from 719,717 to 707,071. The majority of the automatic telephones are located in fifty-one large cities. During 1939 telephones added or transferred from manual to automatic switchboards in these cities totalled 40,769, as against 9,732 in other municipalities.

Health of Glasgow

In his latest report Dr. A. S. M. Macgregor, the medical officer of health for Glasgow, states that the lower death-rates and the reduction in the incidence of common diseases in 1939 recall the experience of London and other cities in that year, but in 1940 Glasgow showed some disquieting features. The general death-rate during 1939—13·3 per 1,000—was the lowest on record. There were fewer deaths due to respiratory and infectious diseases. Infantile mortality fell to 80 per 1,000 births, the usual range being between 90 and 100. Deaths due to puerperal infection numbered 30 as compared with 50 the year before. During the first quarter of 1940, however, there was an outbreak of influenza, and by the end of January the death-rate had risen to 41·1 per 1,000 of the population. There was also an outbreak of paratyphoid fever with 274 cases but only 3 deaths. For the first time for many years measles was prevalent in the summer instead of in the winter. In the later part of 1940 diphtheria in Glasgow, as in some other parts of the country, reached its highest prevalence. Apart, however, from the influenza attack and the prevalence of diphtheria the health of Glasgow was almost as favourable in 1940 as in 1939.

Earthquake in Atlantic Ocean

The United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has determined the provisional epicentre of the earthquake of March 21, 1941, which took place at 7h. 58·4m. G.M.T. This they have found to be at latitude 7·3° N., longitude 38·6° W., which is in the Atlantic Ocean to the north-east of Brazil. The calculations were based on reports from the seismographic stations at Manila, San Juan, Fordham, Huancayo, Philadelphia and Logan, and it is suggested that although the depth of focus is to some extent uncertain, yet it may be of the order of 100 km. Earthquakes in this region are somewhat rare though they are frequently experienced in certain parts of the West Indies; but an earthquake of deep focus in this region is certainly a more rare occurrence, if not entirely without precedent.

Johan August Hugo Gylden (1841-1896)

On May 29 the centenary occurs of the birth of the eminent Swedish astronomer, Hugo Gylden, who for many years was director of the Stockholm Observatory. Gylden was the son of the professor of Greek at the University of Helsinki, and he received a careful training under his father. He also studied at Gotha and Leipzig, and at the former place came under the influence of Hansen. At the age of twenty-one he entered Pulkowa Observatory, and there, under Struve, began his investigations on the orbits of comets and planets. Nine years later he was called to Stockholm as director of the observatory and astronomer to the Royal Academy of Science, and he retained these appointments until his death on November 9, 1896. His papers exceeded two hundred in number, and related to the motion of planets and comets, the rotation of the earth, stellar parallax, refraction, mathematical analysis, cosmogony and other subjects. In 1879 he succeeded Secchi as a corresponding member of the Paris Academy of Sciences. He was made an associate of the Royal Astronomical Society, to which an obituary of him was contributed by his most famous pupil, Backlund.

Announcements

Sir Arthur Keith, lately Hunterian professor of the Royal College of Surgeons, has been elected a foreign associate member of the U.S. National Academy of Sciences.

Dr. Philip R. White, of the Rockefeller Institute, Princeton, has been awarded the Stephen Hales Prize of the American Society of Plant Physiology for his work on plant tissue culture.

The Scientific Instrument Manufacturers Association of Great Britain, Ltd., of 60 Queen Victoria Street, London, E.C.4, has founded a scholarship in optics at the Imperial College of Science, South Kensington, up to £40 per annum, for a minimum of two years. The scholarship will be awarded immediately a suitable candidate presents himself.

Erratum. In the article "The Man of Science as Aristocrat" (Nature, April 19, p. 465), for "the great lens" of the Lick Observatory read "the great mirror".

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

International Democracy of Science during War and Reconstruction

THE central idea of this communication can scarcely be claimed as original or new, but its brief draught has been stimulated by witness of the work of British men of science, admirably continued during these times. Monographs and other volumes, articles of academic or applied scientific nature, and reviews and surveys emanating from Great Britain continue to impress us in the United States with the capacity of British men of science for production of quality under the extreme conditions imposed by modern warfare. Touching on the personal side, recent letters from university friends in England, current publication, without undue delay, of papers written jointly with colleagues in that country, and numerous leading articles appearing in recent issues of NATURE have all afforded me a projected conception of the sane tempo of British scientific activities.

War has paralysed scientific progress in several countries victimized by military aggressors. It has in many ways hampered the activities of scientific centres in Britain. The same conflict is exerting its effects upon American institutions through selective service and the application of increasing thought and research activity to programmes of national economic and military importance.

Years of strife lay stress upon the prime importance of emphasizing in a substantial way the international democracy of science. The responsibility of maintaining this desired status, that progress may resume its full dimensions at the earliest opportunity, lies in the hands of those stronger nations, whose government is by the people. We of the English-speaking countries have as one of our many inevitable co-operative tasks that of implementing recovery from intellectual starvation in those nations whose ideals we share but whose resistance was unfortunately inadequate to stand off the aggressor.

Repair and expansion of the broad highway of learning may be served in several ways during war, to the end that eventual reconstruction may be accelerated among all peoples, affording widening horizons for greater numbers and the furtherance of human well-being and mutual understanding.

Some suggestions for realizing this programme in part during war-time are: increased exchanges of scientific publications, the transmission of more invited and voluntary contributions to foreign journals, and the establishment of additional international journals. A few international journals, published in the United States, supported by capable agencies in democratic countries and having on their editorial boards personnel in and serving the same respective countries, should constitute additional outlets for the publication of scientific work in the event that war conditions continued to increase restrictions already operative. Worthy contributions would be welcome from all scientific investigators who shared the faith in such instruments' *raison d'être*. Nobody is unaware of the deadly factors which militate at present against the successful projection of such a programme. Nevertheless, permitting the defeatists' condemnation of our efforts as mere Utopianisms to befog vision or block action cannot be tolerated. Rather, should not every appeal be made to respective agencies within the free democracies to investigate feasible ways of aiding in the realization of the objectives ?

The much-discussed matter of international exchange professorships could be given support with inestimable profit. In war-time, such exchanges should apply chiefly on a unilateral basis, to enable older or certain highly specialized citizens of involved countries to visit non-belligerent nations, or nations in a state of conflict but removed geographically from the immediate theatre of war. Indeed, the years just preceding this war, and the time elapsed since its inception, have seen the compulsory emigration of a great number of scholars from their home countries, later to find themselves settled, at least temporarily, in free democratic States where a measure of their work may be continued. Admitting that the accommodation of refugees gives rise to numerous problems, it must at once be recognized that the temporary refugee fulfils potentially an important dual function. He brings to the host-country some of his own culture and philosophy and will eventually take home to his own people new views and ideals gained from his sojourn abroad. He thus constitutes one fortuitous and effective means towards the integration of human thought and international understanding.

At the end of hostilities, a point of great importance would be the encouragement and development, on the bilateral exchange basis, of younger investigators especially. Such a plan, brought into extensive operation during the period of reconstruction, would benefit the cause through the advantages offered to the exchange visitors themselves, as well as to their colleagues and students, resident and foreign. Arrangements might be made feasible whereby each home university or other institution would continue to pay the salaries of its delegates, while funds for defraying the expenses of travel might be furnished by university groups, governmental departments or larger private organizations which normally foster foreign fellowships and scholarships.

I held a fellowship which made possible my spending the year between September 1938 and September 1939 at an English university. That experience, with its opportunities for study among stimulating colleagues, and the ever-new adventures in friendship and understanding, has been the prime factor in deepening my convictions summarily expressed in this communication.

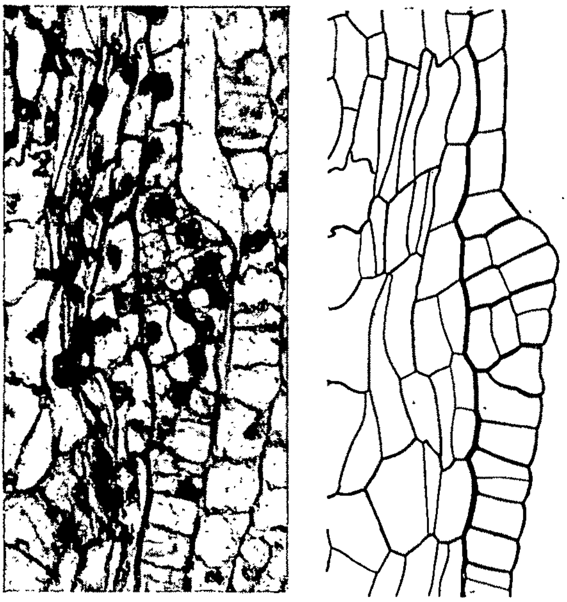
Development of the Ligule in *Zea Mays* L.

During an investigation of leaf initiation and apical organization in grasses, some particularly clear stages in the origin of the ligule were seen in young leaves of maize shoots cut longitudinally in the plane of the leaves. The development of the grass ligule has received attention from only a very limited number of workers (Bugnon[1,2], Ponzo[3], Philipson[4], and Neumann[5]), but all agree that it arises solely from the young epidermis. Neumann well summarizes its origin when he says "The ligule of *Zea Mays* arises from three horizontal rows of epidermal cells lying one over the other".



A *B*

(× 780 approx.)

The photomicrograph *A* and the cell-wall drawing *B* show part of a leaf, about the fifth from the apex, in a maize shoot, and illustrate the way in which the ligule is initiated by rapid periclinal divisions in a few young, rather more densely staining, epidermal cells at the union of the future lamina and sheath. Although periclinal divisions in the sub-epidermal cells accompany the divisions of the epidermal cells, the continuity of the sub-epidermal cells under the ligule and the similar continuity of the rather thicker original lower wall of the epidermal cells indicate that the tissue of the developing ligule is derived solely from the epidermis.

In all of rather more than twenty species of grasses with the simple membranous type of ligule (or *reine Hautligula* of Neumann) which I have examined, the origin is similar to that described for Zea, though it is often difficult to determine how many horizontal rows of cells are involved.

Bracken Compost

In two papers previously published[1] attention was directed to the remarkable effects produced on the growth of young trees by the use of organic composts made from straw and other materials.

In the first instance these composts were used to promote growth of various species of pine on poor heath soils of the Bagshot type. Afterwards, they have been applied with equal success to a number of conifers other than pine, Norway and Sitka spruce, larch, Cupressus sp., etc., as also to birch and beech, and their use extended to various types of soil.

Among the materials tested recently with successful results as a basis for similar composts is bracken, from which has been prepared a compost giving highly satisfactory experimental results in tree nurseries and in the corresponding pot cultures with transported soil. In view of the desirability of eradicating bracken under certain conditions and the accumulation of cut fronds resulting from the methods recommended for that purpose, it seems of some interest and importance that experimental results proving the value of bracken compost should be put on record without further delay.

The methods for making composts successfully used in forestry experiments were described in the first of the papers cited. A standardized product was obtained in every case by careful attention to the size, packing and moisture content of the heaps, with addition of nitrogen at the rate of 1 per cent of the dry weight. The amount of nitrogen has been since reduced to ½ per cent in certain composts without loss of quality, and a bracken compost prepared in this way is at present under comparative observation.

Various sources of nitrogen have been employed, by far the most successful being commercial 'dried blood'. The use of simple inorganic salts of nitrogen such as ammonium sulphate or ammonium phosphate has given composts of inferior quality for forestry work. Under war conditions a satisfactory organic substitute for 'dried blood' can doubtless be found. The successful use recently by Waksman[2] of definite proportions of alfalfa with straw as a basis for composting is worth noting in this connexion.

Bracken compost heaps made as described develop a high temperature and show a well-marked thermophilic phase during decomposition. They break down quickly giving a sweet-smelling friable compost easy to handle. Its value for crops other than young trees requires to be tested.

A recent paper by Braid[3] on bracken eradication recommends cutting down of the fronds in June. Comparative experiments with composts made from dead fronds cut in October and from green fronds cut and dried in early July have given results slightly in favour of the green product, and these results could doubtless be extended to cuts made rather earlier in the summer if found desirable.

Radioactive Copper and the Mechanism of Oligodynamic Action*

INASMUCH as the stimulation of organisms by extremely low concentrations of heavy metal ions (oligodynamic action) is a well-known phenomenon, it seemed desirable to use the artificially radioactive isotope $_{29}Cu^{64}$ (Cu*) to enable one readily to determine the fate of the radioactive copper added to cells in concentrations of the order of 10^{-10} moles per litre.

The leaves of *Elodea canadensis* were immersed in 10^{-6}, 10^{-8}, and 10^{-10} *M* solutions of Cu^*Cl_2 (radio copper kindly supplied by Prof. E. O. Lawrence; the activity of samples was about 10 millicuries per gram) dissolved in quartz-distilled water maintained at 25 ± 0·1°C. in a thermostat and constant carbon dioxide free aeration was supplied. The *p*H was 6·8 ± 0·2 and illumination was diffuse daylight of the order of 5 metre-candles. After required times of immersion, a known weight of leaf material was washed in 500 volumes of distilled water and analysed by the Geiger-Müller counter. The data are shown in the accompanying table. Here it can be seen that while the external concentration of Cu++ is so low that it is difficult to imagine its exerting a physiological effect, nevertheless, in the cell this concentration reaches a very substantial value, exceeding the external solution by almost 3 × 10^8 times at its maximum value. It can be further noted that the organism tends later to eliminate the accumulated radioactive copper and that the rate of uptake of this cation depends upon its concentration. The data for 10^{-8} *M* Cu* solutions are not presented, but they fall substantially between the 10^{-6} and 10^{-10} *M* values.

External concentration (moles/litre)	Cu* concentration in Elodea. (moles/kgm. protoplasm)	Ratio of Cu* inside/outside	Time (hr.)
10^{-6}	0·012	1·2 × 10^4	0·5
10^{-6}	0·050	5·0 × 10^4	1·0
10^{-6}	0·125	1·2 × 10^5	2·0
10^{-6}	0·020	2·0 × 10^4	6·0
10^{-10}	0·019	1·9 × 10^8	2·0
10^{-10}	0·029	2·9 × 10^8	6·0
10^{-10}	0·015	1·5 × 10^8	7·6

These concentrations were found to be physiologically effective, as shown by a comparison of the oxygen consumption of control and Cu++-treated leaves. The effect observed was an increase in metabolic rate. This observation, combined with the failure of distilled water to remove the accumulated radioactive copper, indicates that ions are actually bound in the cell. This bound Cu* cannot be readily exchanged for alkali ions supplied externally, but does readily exchange for Cu++ or Au++. This was shown by placing Elodea in radioactive copper solution for one hour and then transferring to copper, sodium or gold solution and measuring the loss of radioactivity.

It is concluded that copper, in extreme dilutions, exerts its physiological effects by virtue of the power of protoplasm to bind ions against a concentration gradient, so that the concentrations actually present are relatively high. These concentrations later decrease in the cell, and the physiological effect of the heavy metal ion disappears concomitant with this decrease in concentration.

Structure of Vitreous Silica

DURING the last fifteen years, the diffraction of X-rays by vitreous silica has been the subject of many investigations. Parmelee, Clark and Badger[1] obtained one band with a spacing of 7·1 A. and a faint one corresponding to 2·5 A. Randall, Rooksby and Cooper[2] obtained one band at 4·33 A. with copper *Kα* radiation, while with molybdenum *Kα* radiation another faint band at about 1·5 A. was observed. They believe that the faint band obtained with molybdenum *Kα* radiation is spurious and that the only one on which reliance can be placed is that at 4·33 A. Warren, Krutter and Morningstar[3] obtained one principal band at $\sin \theta/\lambda = 0{\cdot}122$. Using an ionization spectrometer, Hartleif[4] obtained two principal bands at $\sin \theta/\lambda = 0{\cdot}06$ and 0·122 respectively. In view of the widely inconsistent results reported by different authors, the structure of vitreous silica appears interesting and worthy of thorough study. The present investigation gives results which differ in many respects from those of previous workers.

With copper *Kα* radiation two series of photographs have been taken. For one series, a Debye-Scherrer camera was used. The specimen was ground in a mortar to a fine powder and then made into the shape of a cylindrical rod. For the other series, the pinhole transmission method was used. In this case the specimen consisted of a thin plate polished down from the lump to a thickness of about 0·5 mm.

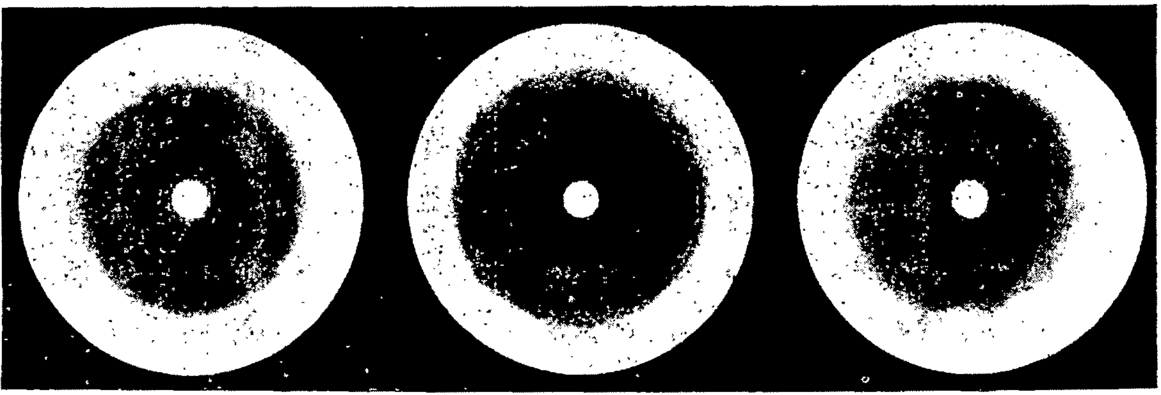
It is rather astonishing to find that the two series of experiments do not give exactly identical results. The Debye-Scherrer photographs show that the diffraction pattern has in general two strong bands *A* and *B* and a series of weak bands *c*, *d*, *e*, *f*, *g*, *h*. The weak bands are so faint and diffuse that they can be recognized only with the utmost care. In certain cases, faint sharp lines l_1, l_2, l_3 appear together with the diffuse bands. Band *A* may sometimes disappear even with the same specimen. The cause of this change is still unknown and is probably some sort of aging effect. With the pin-hole transmission photographs we always obtained two bands *O* and *B*, the relative intensities of which may, however, vary widely with different specimens. Two typical transmission photographs are shown in photographs *a* and *b*.

The accompanying table shows the positions of the bands and the lines and their corresponding spacings (*d*) calculated according to Bragg's law.

	θ	$\sin^2 \theta$	(*h*, *k*, *l*)	*d* (A.)	$\sin \theta/\lambda$
O	5° 04′	0·0088	1 0 0	8·18	0·061
A	7° 37′	0·0176	1 1 0	5·80	0·086
B	10° 50′	0·0353	2 0 0	4·09	0·122
l_1	13° 16′	0·0527	2 1 1	3·35	0·149
l_2	18° 06′	0·0965	3 1 1	2·48	0·202
l_3	24° 08′	0·1671	3 3 1	1·88	0·266
c	32° 41′	0·2916	4 4 0	1·42	0·351
d	39° 29′	0·4043	6 3 1	1·21	0·413
e	52° 44′	0·6333	8 2 2 , 6 6 0	0·96	0·517
f	59° 53′	0·7482	9 2 0 , 7 6 0	0·89	0·562
g	69° 43′	0·8798	10 0 0 , 8 6 0	0·82	0·609
h	75° 58′	0·9412	9 5 1 , 7 7 3	0·79	0·630

It is clear from the above table that our transmission photographs agree exactly with Hartleif's spectrometer results. Most probably the band observed by Randall is really our band *B*, although the value 4·33 A. given by him differs from 4·09 A. by an amount which is beyond experimental error. We failed to identify the band corresponding to 7·1 A. reported by Parmlee, Clark and co-workers.

Column 3 in the table gives the $\sin^2\theta$ values corresponding to various bands and lines. Column 4 gives the plane indexes based on a cubic or pseudo-cubic structure taking the lattice spacing as 8·18 A. The assignment of these indices is perhaps more apparent than real. It does not mean necessarily that our results are in favour of the crystallite theory of glasses, as no crystalline modification of SiO_2 can fall into this scheme. Moreover, the occurrence of the bands and their relative intensities vary with the specimen and with different circumstances. We are not of the opinion that the sharp lines are due to devitrification if the word 'devitrification' has its usual significance, since it is extremely unlikely that when glass is devitrified the diffraction from the crystallites should have but a few sharp lines while the others remain diffuse.



a *b* *c*

The difference shown by the Debye-Scherrer photographs and the pin-hole transmission photographs may be interpreted on the ground that on powdering a glass a certain freedom of re-arrangement is regained[5], thus causing certain changes in the structure. This point has been verified by taking a pin-hole transmission photograph of a slab of powder. The photograph comes out to be the same as that taken with the Debye-Scherrer camera, as shown in photograph *c*.

We have noticed that in the transmission photographs the relative intensities of the two bands *O* and *B* may change even with different locations of the same specimen. This appears to support Prins's idea that the degree of organization of glasses may be appreciably different in neighbouring small regions[6]. In other words, large fluctuations do occur in vitreous silica.

Fourier integral analysis is now being used to investigate from our own photographs the possible radial distribution of the scattering centres.

Band Spectrum of Sodium Hydride

The band spectrum of sodium hydride has been studied by Hori[1,2] and later by Olsson[3]. Olsson concluded from his analysis of the spectrum of NaD that the values of v' given by Hori[2] for NaH should be raised by three units. The results given below were obtained with the view of supplying the missing data for the three lowest vibrational levels of the excited state, which are of especial interest for comparison with the corresponding data for the hydrides of the other alkali metals.

The spectrum was obtained from a discharge tube of the type described by Pearse and Gaydon[4], and grating photographs were taken (dispersions 2·6 and 1·9 A./mm.) in the region λλ 6400–4900. The results of the analysis of the spectrum are summarized below.

Origins of new bands :

(v',v'')	ν	λ	(v',v'')	ν	λ
(2,3)	19659·8	5085·1	(1,6)	16375·6	6105·0
(3,3)	19996·9	4999·4	(2,6)	16705·6	5984·4
			(4,6)	17386·6	5750·0
(2,4)	18638·6	5363·7	(5,6)	17736·2	5636·6
(3,4)	18975·8	5268·4			
(4,4)	19319·5	5174·7			
(5,4)	19669·5	5082·6	(3,7)	16130·0	6197·9
(6,4)	20023·2	4992·8	(4,7)	16473·7	6068·6
(7,4)	20380·4	4905·3	(5,7)	16823·4	5942·5
			(7,7)	17534·6	5701·4
(1,5)	17324·3	5770·6			
(2,5)	17654·3	5662·8			
(3,5)	17991·5	5556·6	(5,8)	15946 4	6269·3
(5,5)	18685·0	5350·4	(6,8)	16300 5	6133·1
(6,5)	19038·8	5251·0	(7,8)	16657·7	6001·6
(7,5)	19396·0	5154·3			

$$\nu = 22719{\cdot}1 + (310{\cdot}6u' + 5{\cdot}41u'^2 - 0{\cdot}197u'^3 - 0{\cdot}00073u'^4 + 0{\cdot}000073u'^5) - (1172{\cdot}2u'' - 19{\cdot}72u''^2 + 0{\cdot}160u''^3 - 0{\cdot}005u''^4),$$

where $u = v + \frac{1}{2}$.

Rotational constants for the lower levels of the excited state :

v'	1	2	3
B'	1·823	1·875	1·908
$-D' \times 10^4$	2·25	2·25	2·20
$F' \times 10^8$	5·1	3·9	3·0

Rotational constants for the ground-leve :

$$B'' = 4{\cdot}886 - 0{\cdot}129u''$$
$$-D'' \times 10^4 = 2{\cdot}76 + 0{\cdot}20u'' - 0{\cdot}021u''^2$$
$$F'' \times 10^8 = 1{\cdot}7$$

It is hoped to publish the analysis soon in greater detail ; further work is also in hand.

RESEARCH ITEMS

Rancidity of Pork and its Prevention

When pork is stored in the frozen condition for subsequent manufacture into 'Wiltshire' bacon, changes are apt to occur in the fat which may become rancid, and in the lean which may lose colour and become dry on the surface. By studying pork kept for forty-eight weeks in various conditions of humidity and temperature, W. H. Cook and W. Harold White have found that temperature is the primary factor concerned (*Canadian J. Res.*, **19**, Sect. D, 53; 1941). The temperatures tested ranged from −6·6° to −23° C. A significant increase in peroxide oxygen occurred in fat with any increase in temperature over −12·2° C., and it was considered that temperature and not the presence of moulds was the prime factor responsible for rancidity. Even at the relatively high temperature of −6·6° C. the content of free fatty acid was small and could contribute little to the deterioration of pork fat. If rancidity is to be prevented over storage periods of approximately one year's duration, storage temperatures of −18° C. or lower are essential. If drying of the surface and the associated discoloration is to be avoided, a temperature of −18° C. must also be maintained, but samples which suffered the greatest colour change during storage showed the least change during subsequent exposure.

Red Sea Corals

C. Crossland deals in a report issued by the Egyptian Biological Station at Ghardaqa with the coral formations, fringing reefs and barriers extending off the shores of the Red Sea for more than 1,500 miles. The coastal areas are also formed from reef structures of recent age; they are about 1 km. wide and seldom more than 20 ft. thick. The fringing reefs are erosion platforms cut into the last with very little addition by recent growth. Outside are irregular areas extending in front of the shore formations; they are often separated by water of much greater depth than in any coral lagoon and thus differ from the regular barrier reefs. Lithothamnioneæ are not constituents of importance, and hence these reefs have no raised edges. Submerged shoals were extensively explored by means of the grab, which gives the most accurate quantitative results. They are mostly flat with edges steep. While all of suitable depth are covered with coral material, this is usually dead. Few living corals were obtained and these of small size, though surface reefs luxuriant in coral life are found in their vicinity. The tables of some proved distinctly deeper than they were when originally charted. Besides these, the echo sounder showed numerous submarine hills still farther seaward. Some of these reach the surface and form shoals or islets rising in water several hundred fathoms deep. Their coral caps do not provide debris to cover more than the first 40 fathoms of their slopes; the Red Sea region does not possess extensive talus slopes round its reefs. Indeed the whole conditions lead Dr. Crossland to think that, on balance, both reef formation and coral growth is now in decline in the Red Sea—a condition also postulated for some coral regions of the Indian Ocean.

Fossil Lizards from Utah

In 1937 a Smithsonian expedition was fortunate to discover a locality in Utah in which the Saurian remains were not only the most ancient known from North America but were the best preserved and articulated yet found on that continent. A preliminary account, by Charles W. Gilmore, of a new genus and species, *Polyglyphanodon sternbergi*, describes a dentition unique among Saurians. The teeth are subacrodont and heterodont, the posterior ones being much widened with sharp transverse cutting ridges. Upper and lower teeth are indistinguishable; there are 6 in the premaxillary, 18 in maxillary and 19 in dentary (*Smithsonian Misc. Colls.*, **99**, No. 16).

Neuroptera of the Nearctic Region

F. M. Carpenter, of Harvard University, has published a revisional memoir on the Hemerobioid division of the Neuroptera (*Proc. Amer. Acad. Arts and Sci.*, **74**, 193; 1940). It is based on the examination of more than eight thousand specimens a considerable number of which were from European museums. The terminology employed is, in the main, that of Killington (1936), but it is noteworthy that the interpretation of the wing venation is based on the findings of the Russian entomologist, Martynov (1928), who showed that the anterior branch of the media has become partially amalgamated with the radius. This conclusion has been confirmed by the late R. J. Tillyard, and also by the author of the present paper. What appears to be the last branch of the radial sector in these insects is, in reality, the anterior media which was previously supposed to be wanting in Neuroptera. One of the most interesting of the lace-wings recorded is the holarctic species, *Psectra diptera*. Rare in Britain, and in no case abundant in other lands, its nearctic range is the north-east part of America. From an examination of forty-four examples the author concludes that the dimorphism shown in this species is not a peculiarity of sex, since both dipterous males and females are recorded in equal numbers. Of considerable interest is the family Polystoechotidæ, which is confined to the New World, and hitherto represented by a single genus. The discovery of a second and new genus, Platystoechotes, from California, is based on a single species named *P. lineatus*.

Alternation of Generations in Perennating Rust Fungi

An interesting account of the alternation of the rust fungus from the binucleate to the uni-nucleate mycelium types, in the case when the rust fungus remains a permanent infection on a perennating host, has recently been published by A. M. Brown (*Canad. J. Res.*, **19**, 75; 1941). Rust-free plants of *Lactuca pulchella* may be infected with *Puccinia minussensis* by inoculating the seedling leaves or the rhizome buds of older plants, with either the æcidiospores or uredospores, or by packing teleutospores into the leaf axil of mature plants and afterwards using the infected nodes as parts of propagation cuttings. However the plant is infected the binucleate mycelium of the parasite makes its way along the shoot and into the rhizomes, but before it reaches the terminal buds of the rhizomes its nuclear condition changes, as only the uninucleate mycelium has been found in the bud scales. Such infected rhizome buds give shoots on which pycnidia alone are seen at first. Thus the alternation from the binucleate to the uninucleate condition depends apparently on the maturity of the host tissue involved and the food supply available to the fungus.

Sugar-Cane Field Experiments

SOME fourteen years ago, the Sugar Cane Investigation Committee of Trinidad embarked on its work with a single manurial experiment on the land of one of the larger companies. The passage of time has witnessed a notable expansion of the original research programme, present-day work being concerned not only with the influence of fertilizers and mixtures of fertilizers on yield, but taking in its stride the effect of such operations as drainage and cultural practices and the response of varieties to different soil types. Since 1936 the number of experiments has remained stationary at an average of sixty-five a year. Some idea of the extent of the work now on hand may perhaps be given by referring to the report for 1940 just received (Ann. Rept., 1940, Sugar Cane Invest. Committee, Trinidad, by P. E. Turner). This report, which is by way of being a straightforward, brief record of many individual experiments, runs to some two hundred and sixty pages and refers to the results obtained, on a variety of soil types, from applications of ground limestone, sulphate of ammonia, potash and phosphate, in various mixtures, and from such by-products as pen-manure, molasses and filter-press mud; while cultural processes included drainage, furrowing, mulching with megasse, and different spacings of plants. Varietal tests alone involved records on nine different soil types. Layouts enabling orthodox use of the analysis of variance have been used throughout. Because of the nature of the work, no attempt can be made here to indicate, even in the most abbreviated form, the many useful and economically important results which have accrued. The scheme, in fact, has justified itself in a most reassuring fashion, and shows in a striking way the service which the modern soil chemist and agronomist can render, even within the brief span of a few years, to agriculture, provided the experimental programme is supported by adequate funds and afforded reasonable facilities.

Sex Chromosomes of Apodemus

P. C. KOLLER (*J. Gen.*, 41, 375–390; 1941) has examined the sex chromosomes of *Apodemus sylvaticus*, the field mouse, and *A. hebridensis*, the local Hebridean race. He shows that these sex-chromosomes have similar general properties to those found in the sex-chromosomes of many other organisms. There is a pairing segment in the X and Y chromosomes and a differential segment in the Y chromosome. In *A. sylvaticus*, the centromere is medianly placed in the pairing segment which may form chiasmata on either side of the centromere. 92 per cent of the spermatocytes show post reduction. *A. hebridensis* has a smaller Y chromosome than *A. sylvaticus* and the fact that post-reduction is obligatory indicates that the distal part of the pairing segment is too small to form a chiasma. The difference between the sex-chromosomes of the two species could be brought about by a change in the position of the centromere through a pericentric inversion. Thus the distal portion of the pairing segment would be greatly reduced and therefore be unable to form a chiasma.

Chromatid Interference

C. L. Huskins and H. B. Newcombe (*Genetics*, 26, 101–128; 1941) have investigated the chromosome configurations of *Trillium erectum* involving pairs of chiasmata. By an analysis of the possible appearances of the chromatids they are able to show that, in 240 bivalents, compensating chiasmata are greatly in excess of non-compensating chiasmata. Hence one chiasma partially determines the chromatids involved in the second chiasma. The simplest types of chromatid arrangement are more prevalent in shorter lengths and also in cells with higher chiasma frequency. Therefore, the distance between adjacent chiasmata has a great effect on the type of chromatid arrangement. Re-examination of genetical data in Drosophila indicates that there may be a similar length-type relationship—short distances are associated with an excess of two-strand double cross-overs (compensating types).

Formation of Martensite on Wire Ropes

WIRE ropes used in mining, and particularly haulage ropes, are subject in service to severe wear which, by reducing the cross-sectional area of the outer wires, gradually reduces the strength of the ropes. A more serious cause of deterioration, difficult to detect and therefore correspondingly dangerous, results from the formation of a brittle surface on the outer wires which leads to their rapid failure by the development of cracks beginning in the brittle layer. In one case where failure occurred microscopic examination of the wires showed the presence of a layer of martensite covering a large area of the worn surface, but having a maximum thickness of only 0·003 in. In a paper discussed before the Iron and Steel Institute (May, 1941), E. M. Trent describes the occurrence of such thin layers of martensite on the worn surfaces of wire ropes. Similar martensitic surfaces have been reproduced in the laboratory by a number of methods, such as striking the wire a glancing blow with a hardened steel tool or rubbing the wire with a steel tool under heavy pressure. The metallurgical structures of the layers are described, and their effect on the mechanical properties of the wire is discussed. It is concluded that the formation of martensite is an important cause of deterioration and failure in haulage ropes, and it is pointed out that care should be taken to prevent such ropes from rubbing against metal objects such as seized pulleys or rollers, rails, steel sleepers, roof girders, etc. Under certain conditions of corrosion the presence of martensite containing cracks leads to the formation of corrosion pits on the worn surfaces of wires. When these pits take the form of what is known as 'chain pitting', they indicate that martensite is probably present.

A Plutonic Phase in Seismic Prospecting

THE phase pP has been well recorded from plutonic or deep-focus, earthquakes. An interesting occurrence, of this same phase has been observed by L. D. Leet (Paper 29, Geophysical Research, Harvard University) in certain seismic prospecting operations.

Velocity calibrations are occasionally obtained by lowering a seismometer into a well and timing the travel to it of waves from explosions near the surface. In the occurrence reported by Leet, records were taken in a well at depths from 2,000 ft. to 5,790 ft. Shots were fired at the bottom of a 46-ft. hole, and a second seismometer was placed on the surface near this shot hole to record the up-hole time of the first wave in the ground. In earthquake terminology, this supplied waves of which the focal depth, travel time to the epicentre, and travel time to a distant station were accurately known. The up-hole time averaged close to 0·015 sec. and the $pP-P$ interval very nearly the 0·03 sec. to be expected under those conditions. At 4,000 ft. and 4,500 ft., according to Leet, pP is actually larger in amplitude than P. It is always well marked, and appears to begin 180° out of phase with P. The abnormal number of crests shown by many reflected groups in routine prospecting is undoubtedly traceable, in part at least, to this dual nature of the incident energy. With shot holes of this or greater depth, there is even danger that pP will be mistaken for a reflexion from a horizon deeper than that which actually returned it to the surface.

Protein Structure

THE cyclol hypothesis of protein structure is considered by D. M. Wrinch (*J. Amer. Chem. Soc.*, **63**, 330; 1941) in relation to arguments against it which have been advanced by Pauling and Niemann (*J. Amer. Chem. Soc.*, **61**, 1860; 1939). It is pointed out that the arguments against the theory based on interatomic distances are not binding, since examples are known in other fields where the chemical evidence is not compatible with these distances. The heat of denaturation which has been put forward as evidence against the theory is shown to depend on bond energies which, it is claimed, are used in a way on which little reliance can be placed. The argument based on the assumption that Anson and Mirsky's denatured trypsin consists of linear polypeptides is claimed to be invalid, as the cyclol theory does not assume the opening of all cyclol bonds, but only that any breakdown of the intact structure is produced by the opening of any subset of cyclol bonds, and it offers an interpretation of the fact that very different denatured products can be obtained from one and the same protein.

Resolving Agent for Carbonyl Compounds

COMPARATIVELY few resolutions of racemic carbonyl compounds are described in the literature. Of several optically active hydrazine derivatives which might be used as resolving agents, many have not been obtained pure and the majority are oils or solids of low melting point. None of them yields readily crystalline derivatives with a variety of carbonyl compounds. R. B. Woodward, T. P. Kohman and G. C. Harris (*J. Amer. Chem. Soc.*, **63**, 120; 1941) have found that *l*-menthol may be readily converted into *l*-menthyl-N-aminocarbamate by the action of ethyl chloroformate in presence of pyridine and treatment of the resulting ethyl *l*-menthyl carbonate with hydrazine. The aminocarbamate (which is called *l*-menthydrazide) is a stable, beautifully crystalline substance which with numerous carbonyl compounds gives stable crystalline derivatives of sharp melting points and definite specific rotations. The use of the reagent was demonstrated by the first successful resolution of *dl*-camphor.

Catalytic Activity and Structure of Metal Films

FROM the laboratories of the Shell Development Company, Emeryville, California, comes a study of the correlation of catalytic activity and physical structure of the catalyst. In the experiments carried out by O. Beeck, A. E. Smith and A. Wheeler (*Proc. Roy. Soc.*, A, **117**, 63; 1940) metal films of high and reproducible catalytic activity were got by condensation on to glass at suitable temperatures. Low-pressure adsorption of hydrogen at room temperature and of carbon monoxide at liquid air temperature showed that oriented gas-evaporated nickel films have twice the available surface per gram of randomly oriented high-vacuum films, but ten times the activity. The oriented films have therefore five times the activity of unoriented films. The activity per unit weight of the films was constant, indicating that the reaction gases easily reached the interior. Adsorption of hydrogen was too fast to be measured. Adsorption isotherms on nickel film were got for ethylene, carbon monoxide, nitrogen, hydrogen and oxygen. The poisoning effect of carbon monoxide and oxygen and the effect of sintering were studied. Most of the work was done with nickel films, but films of iron, cobalt, palladium, platinum and copper were also used. The enhanced activity of oriented films appears to be associated with the larger distances in the (110) plane of nickel or the (111) plane of iron. The bearing of the results on the definition of active centres and on the general problem of adsorption is discussed.

Soft X-Ray Spectroscopy of Solids

AN account is given by H. W. B. Skinner (*Phil. Trans. Roy. Soc.*, A, **239**; 1940) of an experimental study carried out in the H. H. Wills Physical Laboratory of the University of Bristol of the *K*- and *L*-emission spectra from elements of the first two groups of the periodic classification. A characteristic difference between the bands of metals and non-metals was found. The temperature effect on the metal bands is directly connected with the Maxwellian distribution of the conduction electrons and the influence of thermal expansion is appreciable. A large broadening of the valence levels of lowest energy is proposed. In determining the precise features of a band, the crystal structure of the material is the most important factor.

Water on Mars

IT is now seven years since observations of the *B* band in the spectrum of Mars established that the amount of free oxygen in the atmosphere of the planet was negligibly small. Spectrograms taken more recently with a 9-ft. spectrograph at the coudé focus of the 100-in. reflector at Mount Wilson have now been examined (*Astrophys. J.*, **93**, 16; 1941) in order to detect, if possible, water-vapour lines due to absorption in the Martian atmosphere. The region photographed includes two prominent groups of water-vapour lines near 7000 A. Four plates were secured when Mars was approaching the earth, and three when it was receding. Any Martian contribution to the water-vapour lines should thus cause the measured wave-lengths to differ in the two sets of plates. No significant difference is found, however, and the sensitivity of the method enables an upper limit for the amount of water-vapour in the equatorial regions of Mars to be fixed at 5 per cent of that in the earth's atmosphere. These Mount Wilson researches are making the surface of Mars seem less and less inviting for life as we know it on the earth.

AGRICULTURAL LAND AND NATIONAL PLANNING*

By Dr. L. Dudley Stamp

In his speech to Parliament on February 26, Lord Reith made a statement on the duties assigned to him as Minister of Works and Buildings which were summarized as "seeing that all practicable preparations are made for the physical reconstruction of town and country". It was stated that the preparatory work would proceed on certain assumptions including :

"That the principle of planning will be accepted as national policy and that some central planning authority will be required.

"That this Authority will proceed on a positive policy for such matters as agriculture, industrial development and transport."

Lord Reith went on to direct attention to the huge acreage of good agricultural land which has been lost by unplanned development of industry or housing, and it is now clear that planners recognize the necessity and are willing to endorse the fundamental principle of the reservation of the best agricultural land[1]. This is a change of heart compared with the past twenty years, when there has been a clash of interests and a struggle for the same types of land which has fallen with especial severity on the best agricultural land. Level or gently undulating, well-drained land has not only those qualities which go to the making of the finest market gardening tracts but also those suitable for rapid development of housing, for the horizontal layout of modern factories, for aerodromes, playing-fields and even for great reservoirs. When such land is needed for 'development' its development value so far exceeds its value as agricultural land that every time agricultural interests tend to be ignored. National planning will not necessarily provide a remedy, since some of the worst offenders in promoting misuse of good land have been town planners and the powerful corporations behind them.

If the fair apportionment of our national resources of land between the various uses and users is accepted as a primary object of national planning, the reservation of the best agricultural land becomes a matter of immediate and urgent importance and cannot be carried out without the classification of land and the mapping of the categories distinguished.

A preliminary scheme of classification and a tentative small-scale map of England and Wales were prepared at the request of the Royal Commission on the Geographical Location of the Industrial Population by the Land Utilisation Survey[2]. With the co-operation of experts in the varied fields concerned, it has now been possible to elaborate the scheme of classification and to combine the results of county maps prepared by local workers into a general map of England and Wales on the scale of 10 miles to one inch. From this map the approximate acreages and percentages given below have been calculated. The data used are being recorded in the County Reports of the Survey, published under the title of the "Land of Britain".

The classification proposed is a simple tenfold one, based essentially on the broad physical features of the land—quality and depth of soil, elevation, exposure, situation, climatic factors—which remain dominant considerations despite technical progress in the treatment of land by manuring, drainage, etc. Treatment can up-grade land and render it more productive, but does not alter its fundamental character.

Prefixes : *A*—dominantly arable ; *G*—dominantly grassland ; *H*—dominantly heathland, moorland or rough pasture.

A 1. *First-Class Arable Land*, capable of intensive cultivation. Level or gently undulating. Deep, fertile, easily worked loam and silt soils, retentive of moisture and of fertilizers and often naturally rich in humus and mineral salts. 1,785,000 acres or 4·8 per cent of England and Wales.

A 2. *Good Arable Land*, suitable for crop production. Found especially in eastern England where a rainfall of less than 30 inches, and good sunshine, as well as soil and relief favour arable farming and the ripening of corn crops. 5,642,000 acres or 15·0 per cent.

AG 2. *Good General-purpose Farm Land.* Found especially in the west of England where by reason of heavier rainfall it is suitable for ley farming—good grass and a limited range of crops. 1,446,000 acres or 3·8 per cent.

G 3. *First Quality Grassland*, fatting pastures and good dairy pastures. Neutral grassland dominated by rye grass (*Lolium perenne*) and wild white clover (*Trifolium repens*). Mowing meadows yield 1–2 tons of hay per acre, pastures fatten animals without subsidiary feeding. Though not necessarily of lower fertility, much of this land is unsuitable for arable cultivation owing to high water table, periodic flooding or heavy soil. 758,000 acres or 2·0 per cent.

G 4. *Good Grassland.* Neutral grassland with Agrostis and meadow grasses, usually on heavy clay soils which, though fertile, are difficult and expensive to plough. With surface water and small field units, more suitable for grassland farming. 2,875,500 acres or 7·7 per cent.

Mixed *A* 2 and *G* 4 land occupies a further 2,613,000 acres or 7·0 per cent and other areas where the better types of farming land are intimately intermingled cover together another 1,460,000 acres or 3·9 per cent. This gives a total of 16,579,500 acres or 44·2 per cent of England and Wales for the better farm lands.

AG 5. *Downland and Basic (Limestone) Grassland.* Soils usually thin, light and calcareous ; where ploughable (*A* 5) typical arable-sheep-barley land ; where in grass or unploughable (as on Limestone Pennines, *G* 5) traditional fescue sheep-pastures. *A* 5 also includes certain other light-soiled arable tracts. 1,333,500 acres or 3·6 per cent. In addition, there are 1,262,000 acres or 3·4 per cent with an admixture of better land.

AG 6. *Medium Quality Farmland.* Land productive both under crops and grass but which, by reason of slope, climate or soil, can never become first class. Soils generally immature and stony. Includes much of the farm land on the older rocks of western Britain, worked on a system of long leys. Grassland generally acidic or siliceous, dominated by

---

* Summary of a paper read before the Town and Country Planning Conference held at Oxford, March 28-31, 1941.

Agrostis or Agrostis-Festuca, liable to invasion by bracken, gorse, etc., and much in need of liming, manuring, draining or re-seeding. 8,281,000 acres or 22·1 per cent, in addition to which there are 2,010,000 acres or 5·3 per cent with an admixture of better land.

G 7. *Poor Quality Heavy Land.* Land with very heavy, intractable soils or low-lying and difficult to drain. Poor grassland, especially Agrostis infested by rushes (Juncus). 382,500 acres or 1·0 per cent, together with 988,000 acres (2·6 per cent) of which parts have already been improved. This does not, of course, include the huge areas of *AG* 6 and *G* 4 land badly in need of better drainage—probably half of the whole. Medium quality farm land (categories 5, 6 and 7) thus totals 14,257,000 acres or 38·0 per cent of England and Wales.

H 8. *Poor Quality Mountain Land* (Mountain or Rough Hill Pastures). Natural and semi-natural vegetation covering much of the uplands of old rocks especially above 1,000 feet. Thin, poor, stony, immature soils, usually leached and podsolic ; in areas of impeded drainage, acid peats ; in some areas many rock outcrops. Vegetation permits a detailed classification (leading types are Nardus–Molinia moors, Eriophorum moors, heather moors, bilberry moors, etc.) and gives a clue to possibilities of improvement and use. 3,735,000 acres or 9·9 per cent, together with an additional 723,500 acres or 1·9 per cent with improved patches.

H 9. *Poor Quality Light Land* (Lowland Heaths and Moors). Very light sandy or gravelly podsolized soils usually too 'hungry' (that is, unretentive of manures) for economic cultivation. Usually heathland ; suitable for coniferous afforestation or use as open spaces. Includes also some undrained fens and mosses. 316,000 acres or 0·8 per cent, in addition to 1,200,000 or 3·2 per cent mixed with better land.

H 10. *Poorest Land* (Saltings, Rough Marsh Pasture, Shingle, etc.). Land of varied character, but in its present state of little agricultural value, though some (salt marshes) could be reclaimed. 78,000 acres or 0·2 per cent.

As matters of national policy it is suggested : (*a*) that the first four categories, that is, the best agricultural lands, be preserved so far as possible in agricultural use ; (*b*) that major schemes using large areas of land—for green belts, national parks, afforestation, etc.—be restricted to the poorer types of land. Other developments such as new trunk roads of the parkway type can well be aligned accordingly, while some of the poorest land (for example, salt marshes) is well situated for heavy industry ; (*c*) that the integration of land use envisaged by town planning schemes, the establishment of garden cities, etc., is especially important on land of intermediate quality.

The above figures are provisional estimates and include the Isle of Man. Closely built-over areas such as the centres of cities and industrial works are excluded but land already occupied by houses with gardens is included. Calculations of the areas of the latter are being made and the map referred to is now in the Press.

---

[1] See, for example, *Town and Country Planning*, March 1941, where this principle is stressed by the writers of four articles out of five published in that issue.

[2] Summarized in NATURE, 143, 456 (1939).

STRUCTURE OF MOLECULES AND AGGREGATES OF MOLECULES

A SYMPOSIUM on the structure of molecules and aggregates of molecules was held at Columbia University during December 30–January 1, 1941, under the auspices of the Division of Physical and Inorganic Chemistry of the American Chemical Society. Some twenty papers which were submitted at this meeting appear *in extenso* in the January numbers of the *Journal of Chemical Physics* and the *Journal of the American Chemical Society.*

In a short introductory paper, Prof. J. G. Kirkwood, chairman of the organizing committee, points out that "modern physical chemistry is primarily concerned with problems of structure as related both to the properties of systems in equilibrium and to the mechanism of the physical and chemical processes traversed in the attainment of equilibrium". A large variety of theoretical and experimental techniques are, therefore, required to enable the determination of the structure of molecules of vastly different complexities, the structure of molecular aggregates, the nature and magnitude of intermolecular forces, the spatial arrangement of atoms in a molecule or of molecules in an aggregate, interatomic distances, and many other properties. On the theoretical side quantum mechanics lead to a fuller understanding of individual molecules, and aggregates of molecules are being investigated to a very great extent by the methods of statistical mechanics. On the experimental side the structure of simple molecules can be elucidated by a variety of well-established methods ; but to investigate the structure of solid and liquid aggregates is more difficult and, of the available methods, X-ray methods appear to give the fullest information. Thermodynamic properties also shed light on structural theories of gases, but with liquids and solids the evidence from this source is less complete and less conclusive ; nevertheless, increasingly promising results on these latter types are accruing from their statistical mechanical treatment.

The papers, presented at the symposium and briefly summarized here, illustrate the width and variety of the topic and the modern means of tackling its immense unsolved mysteries.

Among the purely theoretical contributions is one by Mayer and Montroll, who have put forward definitions of functions capable of describing the distribution of molecules in a system and have derived equations for their evaluation. When applied to gases, the distribution functions can be developed in power series in fugacity or inverse volume in which the coefficients are integrals involving the mutual potential energy between pairs of molecules. Extension to condensed systems, although possible, renders the equations much more complicated, but their approximate solution can be achieved by application of the cell method involving the probabilities of population of virtual cells.

Quite a different application of statistical mechanics is made by J. C. Slater in attempting to explain the transition in KH_2PO_4. The crystal structure indicates that the PO_4 groups are connected by hydrogen bonds, and thus different orientations of the H_2PO_4' dipoles will arise from different possible arrangements of the hydrogens. When the H_2PO_4' groups are pointing along the axis of the crystal they will have lowest energy, and spontaneous polarization along his axis will occur causing polarization below the Curie point. The statistical mechanical treatment predicts for this transition a phase change of the first order with a sudden change from the low-temperature polarized state to the high-temperature unpolarized state. Experimentally it has been found that the transition is of the second order and is confined to a much narrower temperature range than that predicted by the Weiss theory. But this may be due to broadening of a first-order phase change rising from irregular shifts of transition temperatures in certain regions of the crystal produced by stresses and deformation at temperatures below the transition point. It has been found, too, that the susceptibility above the Curie point, calculated by the statistical mechanical method, agrees, unlike the predicted value on the Weiss theory, with the experimental result. On the other hand, the calculated entropy change is unaccountably 0·11 units less than the observed value.

The existing qualitative ideas regarding hyperconjugation, that is, the conjugation of a group such as CH_3 with groups containing double or triple bonds, are put on a quantitative basis by a quantum-mechanical treatment by R. S. Mulliken *et al.** Hyperconjugation is considered to be omnipresent. Three general types of conjugation are recognized: (*a*) first order conjugation, for example, $HC{\equiv}C{-}C{\equiv}CH$; (*b*) second order conjugation (first order hyperconjugation), for example, $H_3{\equiv}C{-}C{\equiv}H$; (*c*) third order conjugation (second order hyperconjugation), for example, $H_3{\equiv}C{-}C{\equiv}H_3$. Hyperconjugation stabilizes molecules. Bonds are of two types, donor or acceptor; C–H bonds in saturated hydrocarbons are donor and C–C bonds acceptor. As a result of type (*c*) conjugation acceptor bonds gain appreciably in stability whereas donor bonds lose only a small amount of stability. Hyperconjugation confers on C–C bonds approximately 11 per cent double bond character and on C=C bonds about 12 per cent triple bond character. The effects of conjugation in various molecules receive detailed discussion.

Debye, in 1925, explained the salting out of non-electrolytes by their electrostatic interaction with ions, and treated the non-electrolyte as a homogeneous medium. This method is extended and applied to the whole range of composition of alcohol-water mixtures by Scatchard, who takes account of the heterogeneity of the solvent. Satisfactory agreement with experimental data was not obtained probably because account was not taken of the actual structure of the solvent.

The ascertainment of structure is possible by a variety of methods, and the symposium contains several papers on experimental and theoretical aspects of this topic. Beach, in continuation of his electron diffraction studies, contributes a paper dealing with the structure and dimensions of dioxadiene, *p*-dioxene, and furan and two of its derivatives. In electron diffraction work information about the intensity distribution of scattered electrons is at present not very readily obtained. Recent improvements in technique, for example, the introduction of the rotating sector, should soon yield experimental information on this point. It should then be possible not only to determine interatomic distances but also to ascertain their natural degree of indeterminacy. The problem is treated theoretically by Debye by considering the influences of atomic vibrations and of free and hindered rotation of molecular groups on the scattering properties.

The application of X-ray spectroscopy is made by Hoard and Martin* to the structure of oxyfluoniobates. Interaction between aqueous solutions of niobium pentafluoride, NbF_5, and potassium fluoride, KF, gives either $K_2NbOF_5H_2O$ or K_3NbOF_6; and, if HF is added as a third reactant, K_3HNbOF_7 or K_2NbF_7. These are all crystalline compounds and their preparation, crystal forms, and the structures of the different ions are discussed, particularly K_3HNbO_7 which is found to be an aggregate of $K^{\cdot}$, HF', and octahedral $NbOF_5''$ ions, having the salt-like structure $K_2NbOF_5.KHF_2$ and isomorphous with $K_2SnF_6.KHF_2$ and $K_2PbF_6.KHF_2$. On the theoretical side Huggins extends Bragg's photographic method for making a Fourier summation from crystal diffraction data.

Analysis of vibrational spectra of polyatomic molecules is difficult but there are several aids available. An important one is the evaluation of force constants by means of normal co-ordinate calculations. Using a valency-force potential these force constants may be employed to study the character of different bonds and their variation with environment. Crawford and Brinkley examine this problem with reference to the six related molecules HCN, C_2H_2, C_2H_6, CH_3CN, methyl- and dimethyl-acetylene, and they show that stretching constants vary with bond type and with bond length, whereas bending and interaction constants vary only with bond type. To reduce the work of calculating vibration frequencies of complex molecules, Wilson develops various schemes and applies them to the methyl chloride molecule. He derives from these developments a modification of the Teller-Redlich isotopic product theorem. Morse functions, usually calculated from the energy of dissociation, nuclear separation, and fundamental vibration frequency, have been calculated by Hulbert and Hirschfelder, taking into account the additional spectroscopic constants, $\omega_e x_e$ and α_e, and the method is applied to twenty-five diatomic molecules belonging to various classes, for example, hydrogen molecules, hydrides, halogens, oxides, alkalis. The new five-parameter curves give potentials which lie above the Morse curves and indicate that the corrections for moderately large internuclear distances may amount to 10 per cent of the energy of dissociation. Where comparison is possible there is good agreement between observed and calculated potentials.

Smyth* discusses induction, resonance, and dipole moments and assesses contributions to dipole moments from inductive effects and resonance structures for a variety of molecules. He also computes the amount of ionic character in various bonds and obtains values in good agreement with electronegativities derived from thermal data. Comparison of the amounts of double bond character in carbon-halogen bonds in monohalogenobenzenes calculated from dipole moment data with those calculated from interatomic distances reveals wide differences and leads to the conclusion that the amounts of resonance contributions to dipole moment values cannot be accurately ascertained. The significance of this conclusion may be somewhat altered by the revised values of the covalent radii of H, O, N, and F given by Schomaker and Stevenson* who also show that the bond length between two atoms A and B, $\hat{r}_{AB}$ is less than the sum of the normal single covalent bond radii, $r_A + r_B$, by 0·09 times the difference between the electronegativities of A and B.

---

* Papers published in *Journal of the American Chemical Society.*

Groups surrounding a chromophoric group exercise profound influences on the group and may even induce electronic transitions resulting in optical activity. These "vicinal actions" are discussed by Eyring and Kauzmann by reference to a large variety of substances, and they show that optical rotatory power may be utilized in investigating the structure of molecules, provided that due account is taken of "vicinal actions" in calculating optical rotations.

Van Vleck obtains expressions for the susceptibility of an antiferromagnetic medium by means of the Debye vector model and finds tolerable agreement with experimental data. O. K. Rice discusses the equation of state for argon and derives its potential energy curve. The uncertainty as to whether it is the total potential of the electrode or only the overvoltage that is involved in the discharge of gaseous ions has been resolved by Kimball *et al.*, who postulate the existence of two different electrical double layers at the electrode surface and two corresponding energy barriers over which protons must pass. What these barriers correspond with cannot be unequivocally established, but it appears that most probably both correspond to proton transfers from water molecule to water molecule.

Rabinowitch and Epstein* discuss the polymerization of dyestuffs in solution from absorption spectra measurements on thionene and methylene blue. Organic dyestuffs show a universal property of dimerization quantitatively interpretable by London's theory of intermolecular forces. The physical chemistry of insulin is investigated by Cohn *et al.* using the radioactive isotope of zinc (Zn*) and studying the influences of excess Zn*, *p*H and ionic strength on the crystallization and solubility of insulin.

The simultaneous appearance of these papers will prove of immense value to all interested in modern physical chemistry. The topic has so many varied aspects that it calls for large numbers of investigators, each a specialist in his own field. Co-ordination of the contributions of the various specialists is necessary to enable the 'ordinary' physical chemist to appreciate to the full the significance of the various contributions. It therefore seems a pity that the whole symposium was not published in *one* journal and that the discussions on the papers were not published along with them.

CARNEGIE INSTITUTION OF WASHINGTON

YEAR BOOK No. 39 of the Carnegie Institution at Washington covers the year July 1, 1939–June 30, 1940. In addition to the report of the President, it includes reports on the departmental activities and co-operative studies covering astronomy, terrestrial sciences, biological sciences and historical research.

The President, in his report, refers to the intensification of scientific activities in the United States even in fields which are remote from the National Defence Programme. This he attributes to the stimulation of a democracy by the existence of danger, and suggests that fundamental scientific advance, like basic intellectual accomplishment of many kinds, is often accelerated rather than retarded by national stress. The income from endowment continued to decrease, but the current situation was transformed during the year by an emergency grant of 750,000 dollars from the Carnegie Corporation of New York, payable at the rate of 150,000 dollars annually for five years, and the year closed with a substantial excess of income over estimate.

The Geophysical Laboratory and the Department of Terrestrial Magnetism have co-operated during the year in a programme which substantially extends the limits of experimental work on the properties of materials under enormous pressures, utilizing a cascaded pressure equipment with which pressures of 200,000 atmospheres have already been reached, and certain physical measurements can be conducted with material under this pressure. High-temperature studies of anhydrous systems and their presentation by equilibrium diagrams have been continued in the Geophysical Laboratory, as well as studies of equilibrium in systems containing water at various pressures and temperatures. The Department of Terrestrial Magnetism has also continued its studies on the ionosphere as well as its geomagnetic studies on fluctuations in solar radiation, while its activities in nuclear physics have been extended to include a programme of fundamental work in biology and chemistry utilizing the artificial radioactive isotopes of ordinary elements as tracers for following various reactions. This programme centres round a large cyclotron installed last year. Observations at the Mount Wilson Observatory have afforded definite evidence of the presence of organic compounds in interstellar space, and the evidence for the hydrocarbon gas CH and for cyanogen CN′ is almost conclusive. The Department of Genetics has investigated the mechanism by which cosmic rays as well as X-rays cause mutations and hence the appearance of individuals differing abruptly from their ancestors. It has been found that very considerable delay may occur between the fracture of a chromosome and its rearrangement so that reproduction may proceed. Experimental modification of the process, for example, by the use of alkaloids to cause the doubling of chromosomes, yielded much new knowledge. The report includes a review of this work, as well as an account of endocrine studies in the same Department. Biochemical investigations in the Division of Plant Biology have covered the organic nutrition of plants, the use of radioactive carbon dioxide in photosynthesis, and oxidation, reduction and reactions in killed leaves. The report also includes an account of work by Robert Emerson and C. M. Lewis on the quantum efficiency of photosynthesis and the absorption of carbon dioxide in the light and in the dark. Work by the Department of Embryology has covered the physiology of the reproductive system, the endocrine organs, tissue culture and tumour studies, as well as investigations on the nervous system. The report also includes a brief account of investigations in the Nutrition Laboratory and by the Division of Historical Research.

THE NATIONAL CENTRAL LIBRARY

THE twenty-fourth annual report of the Executive Committee of the National Central Library covers the year 1939–40 and indicates the important contribution the Library is making to the nation's war effort. It is a centre which is used by Government Departments, research stations and industrial concerns and a channel through which books immediately essential for war purposes are being regularly supplied. At the same time it is ensuring that essential information is regularly available for those engaged in agriculture, trade and business of all descriptions. Among special war work now being done by the Library mention may be made of assistance given by lending books to the camp libraries which are being established in connexion with the Lord Mayor of London's Services' Libraries and Book Fund by supplying bibliographical information to the Prisoners of War Book Service and by assisting the Sea War Library Service which supplies books to men serving in the Royal Navy and Mercantile Marine.

In July 1939 the Treasury announced that its grant to the Library for the year 1939–40 was to be reduced from £5,000 to £4,800, but a special grant of £100 has been provided by both the Governors of the Thomas Wall Trust and the Trustees of the Cassel Educational Trust to meet this deficit. The Treasury has since announced, in December 1939, that the grant-in-aid for the year 1940–41 is to be limited to £3,500, but this deficit has been met by an emergency grant from the Rockefeller Foundation of 8,500 dollars for the year 1940–41. The number of volumes in the Library was increased during the year from 161,383 to 170,972 and the total number of books issued during the year was 50,611, including 1,191 books issued to adult classes. After the first few weeks of the War there was a steady increase in the number of applications received as well as in the percentage of important books asked for and the requests for bibliographical information. The group of Outlier Libraries now includes 114 special libraries, 2 urban libraries which are not yet co-operating in a regional system and 19 London borough libraries. During the year the Bibliographical Society and the British Social Hygiene Council were added to these special libraries. A total of 491 libraries is now co-operating in the regional system and there are only 24 urban libraries serving a population of more than 20,000 which are not co-operating in this system.

The number of books issued to university libraries, excluding those issued to adult classes, decreased to 3,046 during the year, and 4,440 books were lent by the university libraries to other libraries through the national system. Books borrowed from libraries in other countries for the use of libraries in the British Isles decreased to 159 compared with 283 in the previous year.

Owing to the risk of destruction of property in the centre of London all the Union Catalogues as well as all other irreplaceable or scarce bibliographical material were moved early in September 1939 to Bourne Lodge, Bourne End, Hemel Hempstead, the non-bibliographical books and books belonging to the adult class department being left at Malet Place. This was among the buildings in London recently destroyed by enemy action, and although a large number of books have been saved, many thousands have been destroyed, including the whole of the books in the adult class department and many long and valuable sets of publications. This loss is serious not only to the National Central Library itself but also to all other libraries in the British Isles which depend upon it for the books they are unable to supply from their own shelves.

The Library is still able to give its unique service in arranging loans of books between libraries, the total number of volumes upon which it is able to draw for this purpose being no fewer than 21,000,000. The Trustees have already made arrangements to continue the full work of the Library and it is hoped that funds may be forthcoming to enable them to replace the more urgently wanted books.

NATURAL GAS IN ONTARIO

IN view of the present more or less acute natural gas situation, J. F. Caley has anticipated a comprehensive memoir (now in the Press) by a brief mimeographed report on natural gas in Brantford Area, Ontario*. The report has actually been condensed from the more detailed work and is intended to be an up-to-date guide to operators and others interested in the particular area.

The region known as Brantford area extends for approximately 4,800 square miles from Dundas in the east to Aylmer in the west, and from Mount Forest in the north to the shore of Lake Erie in the south. Commercial production of natural gas is obtained from that part of the area lying south of an east–west line drawn through Paris and comes entirely from rocks of Silurian age, namely, the Medina, Clinton and Guelph formations. Actual productive horizons involved are the fine- to medium-grained sandstones of the Whirlpool (White Medina); light grey and red sandstone and sandy shale of the Grimsby (Red Medina); grey and buff crystalline or granular limestone of the Clinton; and the grey, buff or cream-coloured, crystalline and finely granular dolomite found in the upper part of the Guelph formation.

A map showing structure contours drawn on top of the Clinton and accompanying the report shows that regional structure is monoclinal and has a southerly dip averaging approximately 24 ft. a mile over the whole producing area. Such variations in rate and direction of dip as occur have been caused by unequal settling of the beds and variations in thickness of groups of beds; they are not attributable to folding of the strata. Moreover, there is no apparent relation between structure and presence or absence of producing horizons. Accumulations of natural gas appear to be due to the porous character of certain beds and the existence of small decreases in dip within circumscribed areas.

---

* Canada Department of Mines and Resources. Mines and Geology Branch, Geological Survey Paper 40–42. Preliminary Report: Natural Gas in Brantford Area, Ontario. J. F. Caley. Pp. ii+31+1 map. (Ottawa: King's Printer, 1940.)

There is no evidence to indicate that features favourable to the accumulation of natural gas are confined to those parts of the southern area already in production, neither has sufficient exploratory work been carried out to define by dry holes limits of fields now in operation. It would appear, therefore, that investigations could usefully be carried out both in the northern part of Brantford area where the Guelph and Trenton formations in certain districts offer prospects of production, and also in the several untested, or apparently untested, parts intervening between existing wells in the southern part of the area.

STORAGE OF AUSTRALIAN APPLES

THE Jonathan apple is the chief variety exported from Victoria, between 600,000 and 700,000 bushels being sent overseas annually. Large quantities are also kept in cool storage for local consumption. Two or three pickings are made at fortnightly intervals, the earlier fruits, which are usually green, immature and acidic being exported. The large portion of the crop is picked in a late stage of maturity and considerable wastage occurs due to physiological breakdowns and moulds. With the object of reducing this wastage, Trout, Tindale and Huelin (*Bull.* No. 135, Australian Coun. Sci. and Ind. Res., 1940) have carried out an intensive study of the effect of different factors on keeping quality. The most important are maturity at the time of picking, seasonal and growing conditions, size of the fruit and crop, conditions immediately after picking, and conditions during storage. The ground colour of the fruit is a good index of the stage of maturity in a given district. Immature fruit is not very susceptible to storage disorders, but soft scald and breakdown are more frequent the longer the fruit is left on the tree. 'Jonathan Spot' develops in both immature and over-mature fruit. Soft scald is greatest between June and July and at 32° F. It can be controlled by storage at 36°–37° F. The most mature fruit is most susceptible to breakdown, which is greatest at 32° F.

Mould and Jonathan Spot are greater at higher storage temperatures. Susceptibility to soft scald is increased by short periods at 55° F. and 65° F., before transfer to storage at 32° F., but decreases with longer periods. Cooling to 36°–45° F. immediately after picking is recommended, though the available cool storage space is at present a problem. Storage life can be prolonged by using an atmosphere containing 5 per cent carbon dioxide and 16 per cent oxygen at 36° F. Brownheart occurs with greater concentrations of carbon dioxide. Short treatment with 36 per cent carbon dioxide reduces subsequent soft scald at 32° F. but increases breakdown and Jonathan Spot. The ratio of cane sugar to acid in the fruit is correlated with keeping quality and with the ground colour at picking time.

FORTHCOMING EVENTS

[*Meetings marked with an asterisk are open to the public.*]

Monday, May 26

ROYAL GEOGRAPHICAL SOCIETY (at the Cinema Theatre of the Imperial Institute, South Kensington, London, S.W.7), at 5 p.m.—Colour and Sound Films of India by the Lawrence Thaw Expedition, and of Burma by Mr. Nathan.

Tuesday, May 27

ROYAL INSTITUTION OF GREAT BRITAIN (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Dr. C. F. A. Pantin, F.R.S.: "The Origin of Life".*

Wednesday, May 28

INSTITUTE OF METALS (at the New Clarendon Laboratory, Oxford), at 3.30 p.m.—Dr. F. Simon, F.R.S.: "The Significance of Low Temperature Research" (Thirty-first Annual May Lecture).

Thursday, May 29

ROYAL INSTITUTION OF GREAT BRITAIN (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Mr. W. H. Ansell: "The Re-Planning of London".*

Friday, May 30

PHYSICAL SOCIETY (at the Lecture Theatre of the Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Dr. H. Spencer Jones, F.R.S.: "The 200-inch Telescope" (Twelfth Thomas Young Oration).*

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SENIOR LECTURER IN ENGINEERING in the Oxford Schools of Technology, Art and Commerce—The Chief Education Officer, City Education Office, 77 George Street, Oxford (June 3).

BOROUGH ELECTRICAL ENGINEER—The Town Clerk, Guildhall, Maidenhead (endorsed 'Borough Electrical Engineer') (June 5).

ENGINEER for the Government of Sierra Leone Public Works Department—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1 (quoting M/9552).

LECTURER IN BIOLOGY WITH SOME HYGIENE—The Principal, Training College, Hereford.

LECTURER IN ELECTRICAL ENGINEERING in the Norwich College—The Director of Education, City Hall, Norwich.

SECRETARY—The Director of Research, British Launderers' Research Association, The Laboratories, Hill View Gardens, Hendon, London, N.W.4.

MAINTENANCE ENGINEER for the Transport and Harbours Department of the British Guiana Government—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1 (quoting M/9393).

RECONSTRUCTION AND PLANNING

A NOTEWORTHY illustration of the strength of the national morale is the widespread interest taken in post-War reconstruction. The immediate task of the Ministry of Works and Buildings in speeding up the erection of buildings needed for the war effort is generally taken for granted. It is the contribution of the Ministry to the building of the world we shall live in after the War that captures the popular imagination.

It is somewhat surprising, therefore, that so little attention has been given in the Press to the Conference on National Planning held by the Garden Cities and Town Planning Association at Oxford on March 28–30. However much it may be necessary to postpone the physical reconstruction until after the War, it is essential that the principles upon which our policy is to be based and by which action is to be guided should be elucidated and defined as early as possible, even if only in view of their bearing on the wise direction of our war effort—as, indeed, the Select Committee on National Expenditure has hinted. A summary account of some of the papers appears on p. 684 of this issue of NATURE.

Research is equally important on particular questions and on those involving general policy and principles. This point was well made by Major E. Maxwell Fry in a recent address to the Housing Centre on "Research on a Plan for London". A town-planning scheme must be the result of research into the elements of living, which must be organized in the most efficient manner. The problem in London is concentrated in the provision of good housing, opportunities for adequate leisure and healthy work-places, linked together by efficient transport services. These four elements—work, leisure, housing and transport—are interdependent and form the basis of the problem.

Investigation on the general and on the particular questions must clearly proceed simultaneously if we are to be prepared when the full opportunities arise after the War. Moreover, there are matters in which action may be required during the War to prevent the growth of further obstacles to central development and effective local planning. To some of these attention was directed by Sir Ernest Simon in a paper before the Conference on National Planning on urban land-ownership and management after the War, and Lord Samuel, in a reference to the same subject, welcomed a statement in the House of Lords by Lord Brocket, chairman of the Land Union, that the Union is ready to welcome reasonably devised measures for bringing the use of the land into conformity with the interests of the nation. To problems such as compensation and betterment the Uthwatt Committee is already giving attention, and it may well be hoped that Lord Reith will take action in time to prevent private interests in the devastated districts or elsewhere creating obstacles to developments required in the public interest.

The further attention directed to these matters by the Conference on National Planning is warmly to be welcomed, and the fresh support forthcoming for national planning should at least lead to fuller consideration of the recommendations of the Royal Commission on the Location of Industry.

There are undoubtedly limitations on the extent to which effort can be expended in these directions during war-time. It is all the more important, therefore, that the more restricted opportunities should not be missed. The discussions at Oxford are supplemented by Mr. Ritchie Calder in his Democratic Order Pamphlet No. 5, the theme of which is that we should start planning Britain now. The essential thing is that, as Mr. W. H. Ansell, president of the Royal Institute of British Architects, urged in his paper on "The London of the Future" before the Royal Society of Arts on March 12, we should clarify our general principles and think about those principles before proceeding to particular planning. Too often in the past the thinking has followed the planning, or rather the lack of planning. The immediate urgency is the preparation of the plan in order that when peace comes upon us, it shall not find us unready, and in consequence rebuilding of our cities and factories take undesirable forms.

Mr. Ansell's paper alone is an inspiring picture of possibilities in the planning and rebuilding of London—the redistribution of industries, the re-planning of traffic, of docks and markets, the restoration to the City of something of the glory lost by its congestion, the preservation and encouragement of community areas or the creation of new ones, the re-planning of commercial areas and the architectural opportunities in scientific and fire-resisting reconstruction—possibilities which in varying degrees are inherent in the planning and reconstruction anywhere necessitated by devastation through bombing. The vision of possibilities, when fortified by the determination to use our opportunities, can supply steadiness in the dark days of ordeal which may yet lie ahead, and the stimulus to co-operation in the work of reconstruction, with something of the national unity and energy at present displayed in our war effort.

Several aspects of planning are referred to in two Democratic Order series of pamphlets referred to below*. Mr. Calder ranges concisely over the whole field, indicating mistakes and confusion in the past, the present position, not merely of the Ministry of Works and Buildings, but also of planning and location of industry as resulting from the Barlow Commission inquiry, the weakness of local and regional authorities, and the opportunities and problems which have already been thrown up by the War. With many of these scientific workers are familiar, but Mr. Calder surveys them with a lucidity which should bring home to every citizen the vital need for some definite policy and national planning.

Mr. Calder shows, too, how this question of planning and reconstruction is linked up with the development of social services, particularly with questions of nutrition and medical service, and the tremendous demands it makes on the intelligent use of our resources on scientific lines, whether in such matters as standardization, transport, or the interlocking of agricultural and other industries, food policy and nutrition, and the effect of changes in the age structure of our population upon housing and educational needs and policy. National planning is, in fact, more than the peace aim on which Mr. Calder insists. It is a vital part of our war effort and one of the ways in which we can, as Mr. Francis Williams argues, in "What are we waiting for ?", make democracy not only something to fight for but something to fight with. A determined effort to deal now with the question of planning and all that is involved in working out the lines of policy, not just for physical reconstruction but also for the social and economic reconstruction needed, would give us a most effective weapon for the overthrow of the slavery masquerading throughout the greater part of Europe as the Nazi "New Order".

There are indeed welcome signs that this is increasingly recognized by the Government itself. The whole tenor of Lord Reith's recent statement in the House of Lords was coloured by the assumption that the principle of planning would be accepted as national policy, and that a central planning authority would be established. He has shown himself, further, to possess large and comprehensive views and to be alive to the need for further investigation. The examination of conditions in Birmingham, Coventry and Bristol and the whole-hearted support given to the work of the National Buildings Record are sufficient example. The personnel of the Consultative Panel on Reconstruction already announced by Lord Reith has commanded widespread approval ; indeed, the chief concern at the present moment is that whatever plans are finally accepted should be consistent with the principles that administrative control should not be divided and that the planning authority should have power to put its policy into effect.

This is the main argument of two admirable articles which have recently appeared, one entitled "Problems of Reconstruction. I. Building", in the *Round Table* of March, and the other by Mr. Thomas Sharp on "Planning for Reconstruction" in the *Political Quarterly* of April–June. Both point to the dangers inherent in the large number of Government departments concerned and the imperative need for co-ordination and for the handling of the main groups of problems by specially constituted ministries or sub-ministries, untrammelled by departmentalism. Lord Reith's own Ministry of Works and Buildings is the only example so far of the kind of special department required, and whether or not the present Ministry is expanded into a Ministry of Planning and takes over other functions from the Ministry of Health, War-time Communications, Agriculture, the Central Electricity Board, the Forestry Commissioners, the "National Industrial Board" recommended by the Barlow Commission and the National Park Commission recommended by the National Parks Committee, if the present opportunity is to be used some authority must be given power to plan all post-war land now, and to initiate the bold measures which will make possible the successful execution of a post-war building programme embodying the new approach to social problems involved in the planning of a new and better society.

---

* The Democratic Order. No. 1: What are we waiting for ?: a Call to Britain. By Francis Williams. Pp. 64. No. 5: Start Planning Britain Now: a Policy for Reconstruction. By Ritchie Calder. Pp. 64. (London : Kegan Paul and Co., Ltd., 1941.). 1s. net each.

A scheme suggested in the *Round Table* visualizes the Ministry of Works and Buildings as supreme authority and including four distinct sections. The first of these is the lineal descendant, much expanded, of His Majesty's Office of Works, which, among other functions, might exercise the required control over building and stimulate the far-sighted statesmanship on the side of employers and trade unions required in planning boldly several years ahead. The second is a long-term planning organization concerned with the location of industry and with town and country planning, exercising many of the functions recommended in the Minority Report of the Barlow Commission, including the functions and powers transferred from the Ministry of Health, the former Ministry of Transport and the Commissioners for the Special Areas. This division would co-ordinate the long-term building projects so that too much is not attempted in any one year, but the detailed planning and execution of the building programme of the whole country, both civil and Governmental, would be entrusted to a programme department. Both these departments would work in close contact with a National Investment Board and the National Housing Board.

Besides these three divisions, a housing division is suggested which would take over most of the present housing functions of the Ministry of Health and supervise housing finance through the National Housing Board. The latter would be a purely financial institution, the nucleus of which might well be formed by the building societies; but by accepting responsibilities of landlordship, it would be able to compel builders to accept high standards of design and workmanship. The division would supervise the quality of the houses built and enter into direct relations with the local authorities in respect of the programmes carried out by them.

A centralized plan of this character does not mean the imposition of local building programmes from above. Only national requirements should be planned at the centre. Regional and local details within the national plan should be planned regionally through a series of regional planning commissions, but some one department must deal with all land-using activities if the waste of land and its misdirection from the purpose which best serves the public interest, whether by the speculative builder, the industrialist or the Forestry Commissioners, is to be stopped. Administrative power in a democracy must remain in close contact with the people, their welfare and their desires.

These thoughtful articles are no less insistent than Mr. Francis Williams, in his lively and provocative "What are we waiting for ?", that the start on such planning must be made now, and that we must not allow the attempt to be hampered by the professional tradition or outlook of the Civil Service. Nor need we despair, even with the present demand for man-power, of allocating a proportion to prepare us to meet post-War problems. Obviously some thought is already being given to these matters by the Government. Regional geographers, sociologists, economists, architects and town-planners may be reasonably expected to pay attention to these problems even in war-time.

There should indeed be no insuperable obstacles to the marshalling at the present moment of an effective proportion of the trained intelligence of the nation to the formulation of policy and plans to prevent hindrances to reconstruction developing during the War, as well as scramble, confusion and improvised plans and decisions to meet demands for action which will urgently and insistently arise when the War ends. Only by foresight, coupled with constructive imagination, clear thinking and unflinching loyalty to sound administrative principles throughout the present days of war, can we ensure an adequate recompense after the War for all the sufferings and hardship we have already faced or may still be called upon to endure.

RELATION OF CRIME TO NATION AND RACE

Crime and the Man

The American Criminal

An Anthropological Study. By Earnest Albert Hooton, with the collaboration of the Statistical Laboratory of the Division of Anthropology, Harvard University. Vol. 1: The Native White Criminal of Native Parentage. Pp. xvi+309+482+15. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1939.) 56*s.* net.

IN 1938, when Prof. E. A. Hooton had completed a survey of the bodily features of American criminals and compared them with observations made on corresponding samples of 'unconvicted' civilians, he was invited by the Lowell Institute to give lectures on the harvest he had reaped. These lectures have been published as a book under the title "Crime and the Man"; they give a clear and almost joyous account of a survey of the prison population of ten States, which occupied more than twelve years, included upwards of 17,000 individuals and involved the tabulation and statistical treatment of about 2½ millions of measurements and observations. The criminals and their civil 'control' samples fall into four groups: (1) native whites born of parents who were also born in the United States; (2) native whites born of immigrant parents; (3) white immigrants; (4) citizens of African—or mainly African—origin. Each of these groups is to receive full descriptive and statistical treatment in a separate publication issued by the Harvard University Press under the title "The American Criminal: An Anthropological Study", of which the first volume has now been published. It contains 309 pages of text and 482 pages of tables; vol. 2 will deal with groups 2 and 3; while vol. 3 will deal with the African group.

Prof. Hooton speaks of the publication of this great three-volumed work as "a manifestation of an incredibly non-commercial policy", while the publisher, with equal modesty, claims that "so far as known it is the most extensive anthropological study of criminals ever made". As to preceding works of this nature—why! there is only "The English Convict", published in 1913 by Dr. Charles Goring, in comparison a minor work, of which, by the way, Prof. Hooton, in his outspoken way, passes both praise and blame. I am more sanguine than either author or publisher as to the merits and future of this work. Apart from giving proof that there is a correlation between type of criminal and type of crime, and between race and crime, as well as between nationality and crime, Prof. Hooton deals in its pages with principles which lie at the foundation of anthropological investigation of the living and has opened up important side-lines of inquiry and so produced a work which should be in the library of every anthropologist.

First, let me mention briefly some of the more important of the "side-lines". Prof. Hooton was surprised to find, after he had assembled his data, that each State had its own prevailing anthropological types. There is thus already at work in the United States a tendency to produce local breeds of humanity, due, as Prof. Hooton suspects, to the isolation and inbreeding of the original settlers of the various areas. Students of human evolution, who regard isolation and inbreeding as the main conditions necessary for the development of separate breeds and races of mankind, herein receive encouragement.

Another of the side-line inquiries relates to the process of 'Americanization', namely, that children of immigrants, born in the United States, undergo not only a cultural but also a transformation of body in the land of adoption. There are many, besides the reviewer, who viewed with scepticism the claims made by Prof. Franz Boas that children born to Italian parents in America differ in head form, and in many other statistical details, from the original Italian stock. Scepticism is no longer possible, for Prof. Hooton's statistical inquiries confirm those of Prof. Boas. Of the various nationalities, the Italians undergo the greatest degree of physical Americanization. With such inquiries it is pertinent to compare those made by Dr. H. L. Shapiro[1] on Japanese born in Hawaii. This observer found that the Hawaiian Japanese differed statistically from the immigrant Japanese and these, in turn, differed from the folk in Japan from which they had been drawn. How we are to explain such environmental transformations I do not know, but it is plain that all three of Dr. Shapiro's groups remained unmistakably Japanese.

When he sought to trace the relationship of race to crime, Prof. Hooton had to assign 5,689 white American criminals to one or other of the racial stocks of Europe. He found only 106 that could be classified as purely Nordic in characterization, 145 pure Alpine and 252 pure Mediterranean. Thus only 9 per cent of the total number of criminals were assignable to the three racial divisions into which the majority of anthropologists separate Europeans. Even if we add a fourth division, namely, the Polish or East Baltic, which Prof. Hooton regards as a pure race, there still remained 88 per cent of the prison polulation of America which were unassignable to pure breeds and had therefore had to be placed in mongrel categories. Herein we see a justification for those who maintain that the only living races in Europe are such as are demarcated by national frontiers.

To repel such a suggestion Prof. Hooton might well cite the fact that he has proved that there is a closer relationship between his racial types—nine in number—and a tendency to crime, than there is between national groups and their predisposition to crime. Further, he has found that the kinds of crime to which his small and pure racial groups are prone are more sharply characterized in body than is the case in the larger mongrel groups. Thus the evidence justifies Prof. Hooton's contention that there is a relationship between a criminal's conformation of body and his tendency to commit criminal or anti-social acts. We note, too, that he expects to find a relationship of racial type to social behaviour.

Coming now to the main theme of Prof. Hooton's survey we note that he emphatically rejects the existence of a single representative type of criminal man. He finds that each form of crime—of which he recognizes ten kinds or groups—draws preponderatingly from a civilian group which possesses certain physical characters, as well as social qualities, so that each kind of crime has its own physical type of criminal.

This review has touched only on the fringe of the harvest reaped by Prof. Hooton during the twelve years he spent in a statistical purgatory. His observations on the physique of the insane, on the Negro—in jail and out of jail—his zeal for reform in the treatment of criminals, his forays into eugenics, his attacks on the wrong gods of democracies—all of these have to be passed by with a mere mention. But enough has been said of these two books to tempt anthropologists to study them and, I have no doubt, to profit from them.

A. KEITH.

PRESENT-DAY AERIAL WARFARE

(1) Defence Against the Night Bomber

By Noel Pemberton-Billing. Pp. 191. (London: Robert Hale, Ltd., n.d.) 2*s.* 6*d.* net.

(2) The Military Aeroplane

By E. Colston Shepherd. (Oxford Pamphlets on World Affairs, No. 44.) Pp. 32. (Oxford: Clarendon Press; London: Oxford University Press, 1941.) 4*d.* net.

(1) THE reviewer, when reading this book, was reminded of one of his old professors who was always insistent upon his students never becoming too fantastic in their scientific ideas. He used to say that if he was asked to build a bridge across the Straits of Dover, for the benefit of travellers prone to sea-sickness, as an engineer with a knowledge of the theory of structures he would reply that it was not "impossible", but as a man of the world he would say that it was entirely "impracticable". To use the term "impracticable" is not an unfair criticism of the author's ideas for dealing with night bombers. Remembering his many-sided experience, including some in practical aeronautics, one wonders just how much of this book was written with his tongue in his cheek. For example, his suggestion for covering the country with a mantle of light which would not only blind the raiders but reveal them to the night fighters above them, is logical, and sounds fascinating. But where is all the apparatus, the men to manipulate it, the electrical power, or even the coal to produce it, coming from? It is already obvious to even a lay observer that man-power in the factories is going to be one of the decisive factors in this War.

His prospect of towed fighters sounds good until one asks where all the fuel is to be found, and how collisions are to be avoided. To be effective, a constant patrol over the whole of the country, relatively closely spaced, would have to be maintained. Would not the same amount of fuel consumed, and labour necessary to build and maintain such a fleet, be better expended in preventing the enemy from building bombers by flying over and blowing up his works?

Incidentally, one does not have to understand the technicalities of aeronautics to appreciate the fact that as the R.A.F. so thoroughly smashed the daylight attacks upon Great Britain, the principal problem remaining is to give a night fighter apparatus with which he can detect an enemy machine in the dark. He has already shown himself capable of doing the rest. Upon this problem the book is discreetly silent.

Stimulating reading, as any contact with Mr. Pemberton-Billing always is, but a serious contribution to the scientific aspect of the problem of night defence, No!

(2) This book, No. 44 of the Oxford Pamphlets on World Affairs, is the second written by Mr. E. Colston Shepherd upon matters aeronautical. The other, No. 28, was entitled "Britain's Air Power". These pamphlets are intended to be short, concise explanations of affairs that are necessarily the province of the specialist, written in such a manner that they appeal to the ordinary reader. This volume certainly maintains the high standard of these publications and is well worth reading by those not familiar with the war developments in aviation. It is written in a restrained style, unclouded by the author's personal opinion too often, and presents the situation to-day, written by one who obviously knows much more than he thinks it politic to say in print.

The author explains the meaning and duties of the different types of war machines: the fighter, long-distance fighter, bomber, precision bomber, dive bomber, torpedo carrier, reconnaissance aircraft and army co-operation machine. He then discusses their possible developments and their limitations from the points of view of both their design and use. He finishes with a general discussion upon probable future developments, a dangerous procedure at any time, and particularly so when those developments take place under the stress of war-time demands. At least one of his prophecies has come true since it was written: "The Tornado fighter with its new Vulture Engine should have a speed of more than 400 m.p.h." His whole summing up is exemplified in one of his sentences, with which we must all agree, "Both sides are striving above all for more speed", and if he had added greater range or armament carrying capacity, he would have stated the case even more completely.

THE ULTRA-PERCEPTIVE FACULTY

Exploring the Ultra-Perceptive Faculty
By Dr. J. Hettinger. Pp. 172. (London: Rider and Co., 1941.) 12*s*. 6*d*. net.

IN this book Dr. Hettinger, whose previous work on the so-called ultra-perceptive faculty has already been noticed in NATURE (Feb. 22, p. 217), gives an account of further experiments in the same field, which he has devised partly in order to satisfy the need for a method of inquiry which, he thinks, may enable the faculty to be demonstrated at will.

For this purpose a person is first asked to set his watch at a time prearranged with another person or 'sensitive', who may be at any distance from him—in this case several miles. He is then asked to look slowly for about one hour at some illustrated periodical, reading any short articles that may be of interest and glancing at the illustrations, while noting down the times at which the various items were seen. At the other end the 'sensitive', in company with the experimenter, makes a series of statements which come into consciousness, the only link with the subject at a distance being some object or other belonging to the subject, this article being placed within reach or under the hands of the 'sensitive'. The experimenter then notes what is said by the 'sensitive', jotting down the times of the various statements at intervals of about one minute to correspond with the intervals noted by the subject when reading the periodical.

It is claimed that when the statements made by the 'sensitive' are compared with, for example, the illustrations seen by the subject, close approximation, both in time and subject-matter, is often established in a number of instances. Thus when the subject was looking at a photograph of a large horse, the 'sensitive' was saying, "Some admiration for large cart horses"; and when the subject had a picture of a camera before him the 'sensitive' was saying, "A large camera and bright light". In both these cases and in many others no time lag is claimed, the times being almost, if not quite exact.

Although at first sight the results of these experiments may appear both striking and impressive, it would seem that Dr. Hettinger might have done better to delay publication until he had attempted a much closer and more detailed analysis of his results. In this report he has not printed a single one of the full statements of a 'sensitive' in any one case, a record clearly desirable if the value of the items given is to be properly appraised. Moreover, Dr. Hettinger seems to have been somewhat too complacent when dealing with some of his results which, he thinks, can be accepted without applicable statistical checks and corroborative testimony by independent witnesses. How far he is right in this surmise remains to be seen. Suffice it to say that these findings are certainly of some interest; but it would seem that much work remains to be done and many control experiments devised, before it can be stated with any degree of confidence that here again we have solid evidence that some form of ultra-perceptive faculty has been fully established.

E. J. DINGWALL.

The Anodic Oxidation of Aluminium and its Alloys

By Dr. A. Jenny. Translated by Winifred Lewis. (Griffin's Technological Handbooks.) Pp. vii + 231. (London: Charles Griffin and Co., Ltd., 1940.) 16*s*. net.

THE protection of aluminium and its alloys by anodic oxidation is so important a process that it now constitutes an industry of itself, requiring a specialized literature. This is the first text-book to be produced for the anodic oxidation specialist, and its design to satisfy his needs results in what might at first appear to be a peculiar mixture of chemical, electrical and electro-chemical theory. It is divided into two main parts, the first being devoted to basic electro-chemistry, the chemical properties of aluminium and its alloys, the valve effect at aluminium anodes, and the anodic oxidation process. The second part deals with more practical aspects, such as operating details, the properties and applications of the films produced by different techniques, sealing and dyeing of the films, and chemical protective processes. Brief particulars are also given of the reflector processes and the "Seo" photo process.

One or two criticisms of detail may be made; aluminium does *not* form a useful protective film in chloride solutions (p. 63) and may be very seriously attacked by anhydrous stearic acid in the absence of air (p. 64); and many readers in Great Britain will be disappointed by the limited attention given to the Bengough–Stewart process. Nevertheless, the book must be recommended to all interested in the protection of aluminium alloys.

H. W. G. H.

Wayside and Woodland Trees

A Guide to the British Sylva. By Edward Step. Revised by A. Keith Jackson and A. Bruce Jackson. Pp. xxxviii + 186 + 175 plates. (London and New York: Frederick Warne and Co., Ltd., 1940.) 9*s*. 6*d*. net.

A NEW edition of this well-known work is very welcome, especially in view of the fact that it has been revised by A. K. Jackson of Kew Herbarium and A. B. Jackson of the British Museum (Natural History). Yet we do not like either of the two most outstanding features—the colour photography is attractive but misleading; and what a pity Mr. Henry Irving's superb photographs of trees in winter and summer are not placed on opposite pages. Since they are printed on art paper and inserted, this might have been difficult though not impossible. The authors' claim that this means of making a striking comparison is "rather novel" is not true. It has been done before, but nevertheless it is a great asset to any book on trees.

All trees indigenous to Great Britain are portrayed and described; so also are some exotics which have become established in these Islands. There are two pictorial keys—one based on leaf character in summer, the other on bud character in winter. These, together with the beautiful photographs and the clear and accurate line diagrams and descriptions will make it almost impossible to come across a tree and fail to identify it.

Surface Tension and the Spreading of Liquids

By Dr. R. S. Burdon. (Cambridge Physical Tracts.) Pp. xiii + 85. (Cambridge: At the University Press, 1940.) 7*s*. 6*d*. net.

DR. BURDON'S short treatise can be heartily recommended as a clear, and very concise, account of most of the principal phenomena involving liquids and their interfaces with gases and solids. The methods of measuring surface tension, and the details of spreading of liquids on liquids (including spreading on mercury, to which the author has made notable contributions) are treated in considerable detail; contact angles, with several of their important technical applications, are also described in detail; there are short but sound and clear sections on the relation between intermolecular forces and capillary phenomena, and on monolayers on water. Lubrication and adsorption are also touched upon. The treatment is non-mathematical, only a few formulæ being given.

The book is up to date, and, though brief, manages to convey a surprising amount of information in small compass, references to larger treatises and to original papers being given where necessary. The author usually gives the substance of accepted theory, without, however, sacrificing a pleasing directness and originality of treatment. The book differs from some of the Cambridge physical tracts in being less an account of specialized work in a restricted field than a short introduction to a wide group of subjects, but it should prove very useful.

N. K. A.

Animals in Action

By Dr. Gayle Pickwell. (Whittlesey House Publication.) Pp. xii + 190. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 24*s*.

THIS new book by Prof. Pickwell is similar in format to his three previous publications which, chiefly owing to their superb illustrations, have become well known among naturalists in Great Britain. Again, therefore, must we welcome an admirably produced work, with a stimulating text and sixty-eight arresting plates, most of them single photographs, $9\frac{1}{2}$ in. × $7\frac{1}{2}$ in.

The whole of the animal kingdom is covered, and the subject-matter is considered under the following main headings: general review; animals at home; animals as parents; animals growing up; animals getting food; animal protection; animals getting air; animals getting about; animal kinds; how to know animals.

The author is professor of zoology in the San José State College; but this book makes it clear that he is not only a teacher but also a lover of animals and a master of the technique of photography. The book would certainly broaden the vision of students of zoology or biology (usually so tied down to the examination 'type' system), and it would be treasured by any professional or lay natural historian. Thus it would make a suitable prize or present which could scarcely be surpassed by anything produced on similar lines in Great Britain.

SOYA BEAN CULTURE IN GREAT BRITAIN

By Dr. H. H. Mann,
Woburn Experimental Station, Bletchley

IS it possible to grow soya beans successfully, on a commercial scale, in Great Britain? There is no doubt that if this culture could be established, a most valuable addition to our agricultural resources would be made, for the soya bean is one of the most valuable of the world's oil seeds, besides being capable of many other uses. Yet, except for a relatively small area in Canada, none of it is produced within the British Commonwealth.

At its maximum, the world's production of the bean was estimated at fifteen million tons[1]. The largest grower is China, though in that country almost the whole of the output is consumed as human food. It is Manchuria whose production dominates the world's oil seed market, and there the area in 1937 was nearly nine million acres. In recent years, the United States has entered the front rank of soya bean producers, and now, apart from the very large area on which the crop is simply cultivated for its fodder value, between two and three million acres are grown for seed purposes and a substantial export trade has been built up. Its cultivation as a source of oil has also extended very largely into the Balkan countries, chiefly into Rumania and Bulgaria, where the area before the War was not far from three hundred thousand acres, and into the U.S.S.R., where at its maximum (1931) the crop covered more than a million acres, though this has since been very much reduced[2].

With such large developments of a crop which had formerly been almost a monopoly of northern China and Manchuria, it was natural that interest in its possibilities in Great Britain should have arisen, and for a good many years rather casual experiments in its culture have been undertaken. The chances of success appeared to be considerable. In comparison with most other oil seeds, it has the advantage that it grows commercially under much more temperate conditions than other sources of vegetable oil, and, further, the seeds are a source of a very tasty human food (being, in fact, originally imported as a condiment), while the oil cake forms a rich animal feeding stuff as well as a good fertilizer. The dearth of home-produced oil seeds at the present time would make, in fact, any considerable extension of the crop a matter of national importance.

All early experiments, however, indicated that most of the available types of soya beans would be of no use for seed production in Great Britain[3]. If planted early in the spring, they were ruined by late frosts. They usually ripened so late in the autumn that the seed often went mouldy on the plants before it was ripe, even if the plants fruited at all. Though it seemed possible that there might be a few varieties that could be grown for seed production in Great Britain, the bulk of those cultivated in the more favoured countries proved themselves definitely unsuitable to British conditions.

Attempts have been made, at least since 1914, to select such suitable varieties, and the work of J. L. North at the old Royal Botanic Society's gardens in Regent's Park resulted in the production of types, several of which ripened in September or the beginning of October. These included a brown type which North called 'Brown *C*', and a group of different coloured kinds which he termed 'Jap'. Further, W. Southworth, previously of the Manitoba Agricultural College, settled at Rothamsted in 1932, bringing with him a type derived from the well-known American soya bean 'Ogemaw' and some others, and under his general supervision several of these and North's also have been grown almost every year since then at Rothamsted and Woburn.

The results of these trials with some of the most promising types in existence have not been encouraging for the prospects of the soya bean as a commercial crop. It seems, in fact, to demand three conditions which we cannot give in full measure in Great Britain. In the first place, being rather sensitive to frost, it cannot be sown until serious danger in this direction is over. In 1935, for example, I sowed several varieties on April 25, and a spell of cold weather in May, accompanied by frost, severely checked the early growth though it did not kill the plants. All the varieties I used seemed to be affected. There is clearly danger, except in the extreme south of England, in sowing before the end of April, and this substantially reduces the length of the possible growing season.

Even more important is the second condition demanded by the plant. The soya bean crop seems to require a 'continental' summer, that is to say, a period of higher temperature while it is growing than we can let it have in Britain. Sir John Russell has recently compared, for example[4], the mean monthly temperature during the growing season at Kleinwanzleben (where soya beans have been successfully grown) and at Rothamsted, with the results shown in the accompanying table.

Mean Temperature (Fahrenheit)

	April	May	June	July	Aug.	Sept.
Kleinwanzleben	48·3	53·9	61·3	66·1	65·6	59·8
Rothamsted	44·8	52·5	56·2	60·4	59·4	55·7
Difference	3·5	3·4	5·1	5·7	6·2	4·1

It is this additional warmth that enables the more continental climate of Kleinwanzleben to grow soya beans better than Rothamsted. The same result is brought out if we compare the length of the growing season of certain known varieties. For example, the variety 'Mandarin' is stated by Piper[5] to ripen in 100 days : at Woburn it took 171 days to give me ripe seed. The variety 'Manitoba Brown', reputed to ripen in 85 days, took, with me, 144 days. All these figures would seem to tell the same tale, namely, that summers in Great Britain are not warm enough for the generally used types to give the best results. In summers that have been wet and sunless, such as that of 1936, we were scarcely able to ripen any seed even of the most successful varieties either at Rothamsted or at Woburn.

Thirdly, the time of ripening should not be later than the first week of October, and preferably the last week of September. If later than this, with the wet autumns that are a feature of the British climate, the chance of drying the ripened crop so that it can be stacked or threshed is small. In the year 1935, for example, I was able to reap the variety 'Manitoba Brown' on September 21, and got it in good condition. The later variety 'Mandarin' was only cut on October 21, yet at this date the beans were not thoroughly ripe, but rather soft.

In spite of these difficulties, certain varieties have been successfully cultivated in a series of years. Recently, Dr. H. Hunter of the National Institute of Agricultural Botany at Cambridge has pointed out that he has got two varieties, namely, 'Brown *C*' and 'Jap', which have a tolerable chance of ripening in Great Britain. Our results entirely agree with his, both at Rothamsted and at Woburn. The 'Jap' types, however, though they have certainly ripened, are very feeble growers. The Brown type, which we call 'Manitoba Brown', but which seems to be identical with Hunter's '*C*', has done better, and in most years since 1934 I have been able to get a normal ripening of good seed, though with a much longer growing season than is customary in Canada, from which country the seed is derived.

But I have never been able to get a yield of seed comparable with what seems to be usual in Manchuria, in the United States, or elsewhere. The yield, in fact, recorded in Manchuria, Japan and the United States runs about 15 cwt. per acre, whereas I have not been able to get more than a maximum of about 6 cwt. per acre of clean seeds. In the course of my trials, I early found that soya beans would not grow at all well unless the land were at least of average fertility. The common idea that the crop can be grown on poor land and reliance placed on its leguminous character to obtain large healthy plants when nitrogenous matter is deficient in the soil is incorrect. Now, I always use soil which has been well manured with farmyard manure some months before planting, and, in 1940, I also used a small dressing of sulphate of ammonia at the time of seeding. But, in spite of this, as already stated, I have never been able to get a large yield. My best was 635 lb. of clean seed per acre in 1938, with the 'Manitoba Brown' variety. Other types which have ripened successfully at Woburn have been 'Black Jap', 'Green Jap', and one obtained from Japan by Southworth called 'Tokio Brown'. All these were less luxuriant than 'Manitoba Brown', and certainly were not earlier. None of them gave me more than 300–400 lb. per acre, the 'Black Jap' being the best.

In order to reach even this yield, the seed was sown between April 25 and May 15. In an average season, probably about the first week in May is the best time. I have always dibbled the seed in rows eighteen inches apart, the dibbles being from six to nine inches apart in the rows. For a non-luxuriant type like all those mentioned, this is probably, if anything, too wide seeding. I have never had any difficulty with germination, but the young plants are very attractive to all sorts of vermin. If growth is normal, the flowers appear on the lower parts of the plants about the middle of July. In 1940, I noticed them on July 22, and flowering was continuous from that date. On August 9 there were clusters of pods on the lower part of the stems and very small pods on the upper parts. When the crop is ripening, the leaves all fall off, and, when ripe, there are practically clean stems with the pods on them. The varieties with which I have been successful have ripened at the end of September, and they were then cut, spread to dry, and, when dry, were at once threshed.

A yield such as I have obtained is not encouraging for the development of a commercial soya bean culture. In spite of the fact that the seed contains between 16 and 20 per cent of oil (of which it is usually counted that 15 per cent is commercially recoverable), and that it has certain other advantages such as its tasty character, it would, at present, pay better to grow the ordinary field bean unless the yields I have obtained can be increased very largely. This small yield in conditions obtaining in Great Britain has, up to date, discouraged even the most enthusiastic growers.

The possibilities for the future seem to depend on the development of types which yield more heavily in our climate than any of those tried hitherto and which are still early enough to ripen at least by the first week in October, and on finding cultivation methods which give again a larger yield than those I have hitherto adopted. I am not unhopeful of the chances in both these directions, but a very great deal of work will be required before the cultivation of the soya bean can take a large part in ordinary farming practice even in the south of Great Britain.

PROBLEMS OF THE MOTIONS OF SOLAR PROMINENCES

BY M. A. ELLISON

YEARS of great solar activity, like those of 1937–38, stand out as landmarks in the advance of our knowledge concerning the phenomena of the solar chromosphere. The quantitative study of prominence motions is little more than twenty years old and derives the greater part of its observational material from the peak years (1926–27 and 1937–38) of the last two solar cycles. Indeed, the recent studies by Max Waldmeier[1] with the spectrohelioscope suggest that at times of maximum activity great eruptive prominences occur on the average about once a day somewhere in the solar chromosphere. They may form the normal, though dramatic, end-phase in the life of every quiescent prominence.

Because of their great size and amazing speed, the eruptive prominences have been more extensively investigated than those of the other four main types; yet we are still without an acceptable theory which will explain, even qualitatively, the characteristic and well-marked stages in their life-history. They originate in all solar latitudes, and show no preference for the sunspot zones, where either the intense magnetic fields of the spots or the occurrence of chromospheric eruptions, emitting ultra-violet radiation, might provide a satisfactory basis for a theoretical discussion of their movements. As an example we may quote the case of the great prominence of September 17, 1937, whose "crowded hour of glorious life" was photographed at the McMath-Hulbert Observatory. This rose in 80 minutes to a height of 1,000,000 km. above the sun, attaining at the end of its trajectory a maximum speed of 728 km./sec. It must be admitted that this is a record for such objects in speed, though not in height; it forms the only example, certainly observed, of matter leaving the chromosphere with a speed in excess of the escape velocity of 617 km./sec. It is a thrilling moment for any solar observer when a quiescent prominence, perhaps 100,000 km. in length, begins to rocket upwards in the field of the spectrohelioscope; and within the past few years these events have been made visible to a wider audience by the superb films of solar phenomena which we owe principally to Dr. B. Lyot of Meudon, and Dr. R. R. McMath and his co-workers in America.

Observations of eruptive ascents were first collected together by Dr. Edison Pettit, of Mount Wilson Observatory, in a celebrated series of papers[2]. His catalogue now includes some fifty examples for which the photographic records are sufficiently complete to enable height-time diagrams to be plotted. On the basis of the earlier observations the following laws of motion were formulated:

Law 1.—The motion of a portion of a prominence or of a prominence as a whole measured along its trajectory is uniform, increasing suddenly at intervals as if by impulse.

Law 2.—When a change of velocity takes place, the new velocity is a small whole multiple of the old. Occasionally the *last* velocity is a whole multiple of the second previous.

Concerning these two laws there has been much controversy, and they have undoubtedly provided a great stimulus to research. Dr. McMath observes: "To say that these curious laws of prominence motion are mysterious is very definitely an understatement. They contradict every known law of the motion of particles under the action of a gravitational attracting centre; it is as though acceleration in prominences functioned only in 'definite acceleration quanta' "[3]. The nature of this motion is illustrated in Fig. 1, which may be regarded as being typical of the height-time diagrams for eruptive prominences. The initial upward velocity of 10–50 km./sec. is represented by the constant gradient AB. Sudden changes of velocity occur at points like B, C where the abrupt

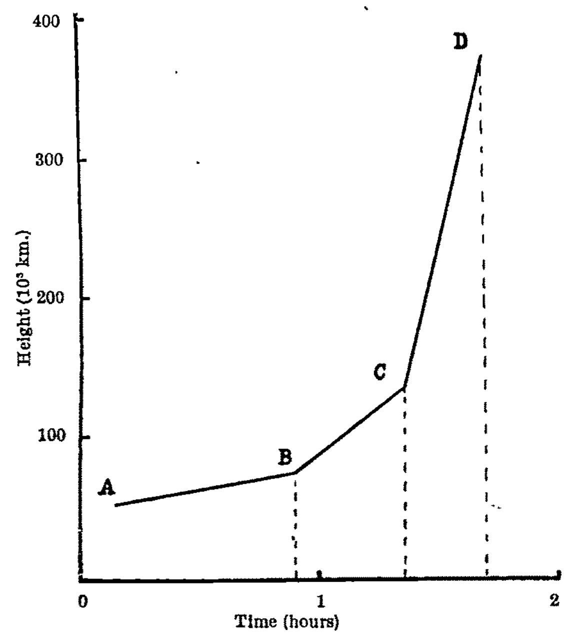

Fig. 1.

changes of gradient (*Knickstellen*) indicate velocity increases which (according to Pettit) are small whole multiples of the original. It has been shown that these changes occur in periods of less than 1 minute and that they are separated by intervals which tend to become progressively shorter as the prominence rises. As many as five such changes have been recorded in a single ascent.

The earlier records were obtained exclusively by photography with the conventional type of spectroheliograph in light of the H and K lines of calcium or $H\alpha$ of hydrogen. The usefulness of this method of following rapidly changing structures was limited by the need for long exposure intervals of 4 or 5 minutes ; short-lived changes were lost and measures of height became insufficiently frequent. A great advance was therefore made in 1933 by Dr. McMath[4], who combined a standard motion-picture camera with the visual spectrohelioscope developed by G. E. Hale, leading at once to the possibility of more rapid and automatic operation. So successful were these preliminary experiments with the spectrohelio-cinematograph that they were followed very soon by the building of the 50-ft. tower telescope and automatic spectrographs of the McMath-Hulbert Observatory[5], Lake Angelus. Difficult technical problems had to be overcome, such as the provision of a precision drive to the 22-in. cœlostat mirror which would keep the image of a prominence fixed at a definite point in the film frame throughout the day, and the construction of timing and exposing devices.

With the completion of this powerful unit in 1937, it became possible to obtain as many as one thousand pictures a day of a single prominence, exposures being of 10–30 sec. with a 'dark-time' of a few seconds in between. The films have been shown in Great Britain before the Royal Astronomical Society and also during the Cambridge meeting in 1938 of the British Association. When they are projected in the usual way at 16 frames per second, there is a speeding up of the original events by about 500 times, from which one may gain a remarkable insight into these weird and complicated movements. One result has been to confirm what was first pointed out by H. W. Newton[6], that the downward movements greatly predominate over the upward, and several new types of prominence have been added to the existing classification. Of these, perhaps the most puzzling are the so-called 'coronal prominences', consisting of matter which first becomes luminous at heights of 250,000 km., or thereabouts, and then pours down in slender columns into centres of attraction in the chromosphere. The downward movements are usually unaccompanied by any visible upward flow to sustain them.

For purposes of measurement, the cinematograph pictures were projected on to a ground-glass screen, 20 cm. × 25 cm., from which the distances moved by selected knots or streamers could be read off along suitable scales. It then became possible to extend the work to the movements of other types of prominence, in particular the class III, or spot-type, of the Pettit classification, with results which, it was claimed[7, 8], demonstrated that all obeyed the two laws of motion. This conclusion has been challenged by H. R. Hulme[9], who bases his criticism upon an analysis of some of the space-time diagrams for descending matter drawn by McMath and Pettit. He shows that these are composed of points which might equally well be fitted by smooth curves rather than by straight lines, and concludes that "the second law is unfounded, and that the application of the first law to the case of descending streamers is not yet justified".

Undoubtedly one of the great causes of uncertainty in this work arises from the fact that the photographic records are two-dimensional. However uniform may be the movement of a prominence streamer along its own trajectory, its velocity will not appear uniform if the plane containing the trajectory is steeply inclined to the normal plane ; and it is here that the spectrohelioscope, used for visual observations of the chromosphere and prominences, has proved of great value. In this instrument the Doppler effect can be utilized in a simple way to measure the line-of-sight velocity of prominence features on the sun's limb, or when seen projected as dark hydrogen absorption flocculi on the disk. Waldmeier[1] has thus been able to obtain a three-dimensional picture of the movements of some of the eruptive prominences observed at Zurich, and he concludes that the second law of Pettit does not hold for the eruptives. The direction of future advance would therefore seem to rest with the possibility of developing a technique for the automatic recording of line-of-sight velocities in such a manner that they can be combined with those obtained from the two-dimensional photographs. Furthermore, when prominences are observed with the spectrohelioscope and are seen as absorption markings projected against the solar disk, curves may be plotted between the line-of-sight velocity and the time. Near the centre of the disk, if the prominence is moving vertically in the chromosphere (as may often be demonstrated by the absence of simultaneous lateral movements), the velocity-time curve will give a true picture of its motion[10].

The remarkable films taken by Dr. Lyot differ from those of the American workers in being direct photographs of solar phenomena. Through superior technique, Lyot has achieved success[11] in this direction where earlier attempts conspicuously failed; and he has been able to develop the coronagraph, in which instrumental diffusion of light has been reduced to a minimum. With such an instrument situated in the clear air of the Pic du Midi, 9,000 ft. above sea-level, photographs of prominences may be taken through suitable filters on many days of the year. In one important respect the method is superior to the use of the spectroheliograph; for the absence of any narrow selecting slit (inherent in the spectroheliograph) allows a record of prominence streamers with high radial velocities to be obtained at the same time as those with little or no radial velocity. The general agreement between the two methods is therefore most satisfactory, since it indicates that radial velocities of 100 km./sec. or more, which would shift the image right off the second slit of the spectroheliograph, are comparatively rare in ordinary prominences.

Numerous attempts have been made to provide a theoretical basis for the first law of motion, bearing in mind the nature of the forces which atoms in varying degrees of excitation may experience in the chromosphere. At the very least we must take into account the effects of gravitation, light-pressure, magnetic fields and frictional resistance.

An attractive starting-point is to assume that in the chromosphere and prominences gravity is balanced by light-pressure; calculations of the magnitude of the light-pressure indicate that this is so, though it must be admitted that we are not sufficiently certain of the processes involved to be assured of the result. In any event, if such an equilibrium does exist, it must be expected that the Milne effect will frequently intervene to upset it. Milne[12] proposed that when a prominence began to rise by reason of some small local disturbance in the chromosphere, its absorbing line would shift to the violet in consequence of Doppler effect; here it would encounter the much more intense continuous spectrum with corresponding increase in light-pressure. A condition of instability would be the result, the prominence continuing to rise with *accelerated* velocity. Pettit and McMath[8] have worked out in detail the consequences of this instability, taking into account the known contours of the K and H absorption lines, and have shown that it would lead to a height-time diagram which is a continuous curve, quite unlike the observed movements of the eruptive prominences. Moreover, the great difference in masses of the atoms of hydrogen and calcium should tend to produce a considerable separation of these gases during the ascent. This has never been observed; indeed the spectroheliograms taken by light of the two different wave-lengths have always shown the images to be remarkably alike.

K. O. Kiepenheuer[13] has considered the motion of prominence material to be expected in the magnetic field of a sunspot, and he arrives at a result for the knots and streamers of class III (sunspot-type) prominences which indicates uniform motion. He finds also that the motion of the eruptive prominences is consistent with the supposition that their atoms receive energy intermittently by absorption of ultra-violet radiation, having its origin in frequent chromospheric eruptions. Against this must be recorded the fact, demonstrated both by Pettit and Waldmeier, that the change-over from one uniform velocity to the next in an eruptive prominence occurs in a period that does not exceed one minute, while the average duration of observed chromospheric eruptions is about twenty minutes. Furthermore, the chromospheric eruptions are very definitely confined to the sunspot zones, while the eruptive prominences are not.

It is evident that a workable theory for prominence motions is one of the great needs in solar physics to-day.

SPECIFICATIONS FOR NATIONAL FLOUR

THE Accessory Food Factors Committee of the Lister Institute and the Medical Research Council, in a memorandum issued in the summer of 1940, recommended the adoption for bread of a flour of 80–85 per cent extraction of the wheat, in the following terms : "Flour for the bread of the people should contain the germ of the wheat grain, as much as possible of the aleurone layer, and the finer portions of the bran. Instead of flour consisting of about 70 per cent of the wheat grain, as it does at present, the percentage extracted should be at least 80 to 85 per cent".*

Since this recommendation was made, the Ministry of Food has decided to make generally available to the public bread baked from flour of 85 per cent extraction.

In the original memorandum the nutritional considerations on which the recommendation was based were set out. It now seems desirable to re-state them, incorporating the results of further research and defining more exactly the character of the particular 85 per cent extraction flour recommended by the Committee.

SPECIAL NUTRITIVE PROPERTIES OF THE SELECTED FLOUR

The degree of extraction was fixed at 85 per cent in order to secure a flour which should contain :

(1) As much as possible of the B vitamins including riboflavin and nicotinic acid and especially of vitamin B_1, present in the whole wheat.

(2) As much protein as possible, including a high proportion of that situated in the outer layers of the grain. This protein is known to possess a higher nutritive value than that contained in white flour.

(3) As little bran as possible so that there should be no risk of loss of nutritive value due to presence of much indigestible material. War-time diets already contain much vegetable food with relatively large amounts of roughage ; it is undesirable to increase this further.

PRODUCTION OF FLOUR OF 85 PER CENT EXTRACTION

Flour of 85 per cent extraction can in practice be obtained by two general methods : (1) by rearrangement of the milling machinery to produce a flour containing 85 per cent of the wheat, or (2) by addition to the white flour (73 per cent extraction), obtained in the ordinary milling processes, of combinations of the other fractions of the wheat.

The consideration which has influenced the final selection of the flour to be adopted has been the need to combine two qualities : first, the best nutritive value and, secondly, the production of a loaf as little removed as possible in colour, texture and flavour from that of ordinary white bread. Two flours, prepared respectively by the above methods (1) and (2) were selected as possessing equal nutritive value, the first, however, being preferable as fulfilling the second condition most perfectly. Flour (1) was selected as the best for the following reasons :

(*a*) Of all flours obtained at the same level of extraction by different methods from the same grist, it had the highest vitamin B content and in this respect closely approached that usually accepted for wholemeal bread.

(*b*) It had the lowest fibre content compared with other flours extracted at this level from the same grist.

(*c*) Of all the breads tested, baked from 85 per cent flour, it yielded the one which resembled white bread most closely in flavour and texture.

(*d*) The colour of the bread was pale brown and was not unattractive.

(*e*) On technical and on æsthetic grounds the loaf baked from it was considered excellent.

DEFINITIONS FOR TWO SELECTED FLOURS

Flour (1).—This straight-run flour may be defined as a flour containing 85 per cent by weight of the clean wheat, in which is included (*a*) the maximum amount of the germ and of the aleurone layer and (*b*) the minimum of the pericarp, as shown by its low fibre content.

Flour (2).—May be defined as (*a*) containing 85 per cent of the weight of the clean wheat grain in which is included all the white flour, all the reduction roll tails, mill finish and purifier tails and sufficient fine bran to bring the amount of the mixture up to 85 per cent of the clean wheat ; (*b*) containing 85 per cent of the clean wheat and excluding 15 per cent consisting of the bran and pollards.

Analyses of samples of flours (1) and (2) are set out in the accompanying table below, with those of white flour of 73 per cent extraction and of wholemeal flour, all four materials being derived from the same grist (water content being 15 per cent).

Samples of flours (1) and (2), obtained from the same grist, were found to be similar in content of protein, ash and vitamin B_1, which in both cases was more than 1 I.U. per gm. (thiochrome methods). The fibre content of both flours was less than 0·9

---

*See also NATURE, 146, 117 (1940).

Flour	Fibre %	Ash %	Protein %	Vitamin B_1 International Units per gm. (thiochrome method).	Calcium mgm. %	Phosphorus mgm%	
						Total	As phytic acid.
1 (85%)	0·60	0·90	11·4	1·2	27	203	123
2 (85%)	0·85	0·94	11·5	1·15	27	211	128
White (73%)	0 to 0·20	0·46	10·6	0·35	15	101	35
Wholemeal (100%)	1·8	1·51	11·9	1·4	36	343	246

per cent that of flour (1) being lower than that of flour (2). The lower the fibre content the better is the flour and the more efficient is the milling.

KEEPING PROPERTIES

No exact evidence is as yet available regarding the keeping properties of the particular types of flour selected, but from the experience gained of other brown and wholemeal flours there is little doubt that this flour of 85 per cent extraction could be kept in good state under reasonable conditions of storage for 4–6 weeks or longer.

RECOMMENDATION 1

The Accessory Food Factors Committee, at its meeting on January 23, 1941, recommended that a flour of 85 per cent extraction (similar to flour (1)) should be adopted.

Since modification of ordinary milling machinery would be required for production of flour (1) and this would take time, it was further recommended that a flour of 85 per cent extraction (similar to flour (2) should be adopted in the meantime, as this could be produced without any delay. The flour should not contain less than 1 I.U. vitamin B_1 per gm. and the fibre should be less than 0·9 per cent (assuming a water content of 15 per cent).

ADDITION OF CALCIUM SALTS

It is known that the intake of calcium salts in the diets of Great Britain, especially among the poorer classes, is frequently below the minimum accepted by nutrition experts as necessary for satisfactory growth of bones and teeth in growing children and for maintenance of the bones in adults. The addition of calcium salts to bread was recommended in the previous memorandum issued by the Medical Research Council. It is now possible to add details concerning the amounts required.

Wholemeal bread and bread made from flour of 85 per cent extraction contain more calcium than white bread and also more phosphorus. A large proportion of the phosphorus, however, is present in a combination (phytic acid) in which it is not directly available to the organism and at the same time diminishes the availability of the calcium present in the bread and in the rest of the diet. Recent tests made on human subjects for the Medical Research Council have shown that to maintain a sufficient supply of calcium salts for health more calcium salts must be added to the diet. The most convenient way to do this is to add calcium carbonate to the wheat flour used for bread. As a result of the above tests on human subjects who consumed about one half of their total calorie intake as bread with only small amounts of milk and very little cheese, it has been calculated that additions are needed of 65 mgm. calcium per 100 gm. white flour (7 oz. of calcium carbonate as *creta præparata* B.P. per 280-lb. sack) and of 130 mgm. calcium per 100 gm. flour of 85 per cent extraction (14 oz. calcium carbonate per sack). In the case of the 85 per cent extraction flour the extra 7 oz. per sack is required to neutralize the effect of the extra phytic acid contained in flour of this degree of extraction.

It has long been a practice in baking to add similar amounts of substances known as 'improvers' (for example, acid calcium phosphate 12 oz. per sack, or up to 4½ lb. per sack, in case of certain self-raising flours at present on the market).

The addition of the recommended amounts of calcium carbonate to flour has no effect on the vitamin B_1 content of the flour or on its baking properties.

RECOMMENDATION 2

It is recommended that calcium carbonate (as *creta præparata* B.P.) should be added to the wheat flour from which white bread is made in the proportions of 7 oz. per sack (280 lb.) of white flour and of 14 oz. per sack of 85 per cent extraction flour.

ADDITION OF IRON SALTS

The desirability of adding iron in some form to flour has been considered, the reason being that anæmia due to insufficient iron in the diet is common in Great Britain and could easily and cheaply be prevented by administration of simple ferrous salts. A study of the available data on this subject has, however, led to the conclusion that the presence of added iron salts in flour might cause destruction of some of the other nutrients present. It is, therefore, not recommended that any such additions be made until further knowledge on this point is available.

ADDITION OF 'IMPROVERS'

The addition of certain 'improvers' to bread baked from flour of high extraction facilitates the work of the baker and results in a more attractive loaf. Such evidence as is available does not justify at this stage the prohibition of their use in the baking industry and the question has therefore been left open.

OBITUARIES

Sir Albert Seward, F.R.S.

We regret to record the death of Sir Albert Seward on April 11 at the age of seventy-seven. Albert Charles Seward achieved outstanding success as an investigator, a teacher, a writer and an administrator. Most of his life was spent in Cambridge, where the University and two of its colleges owe much to his untiring energy, but his work also extended over a much wider field and few scientific men have been so widely known and so universally popular.

Born at Lancaster in 1863, he was educated at Lancaster Grammar School and St. John's College, Cambridge, of which he was three times a fellow. From his school days he was devoted to the study of botany and geology, and his border-line researches benefited both sciences. His early interest in fossil plants was stimulated by W. C. Williamson, the founder of modern palæobotany in Great Britain. His first papers appeared in 1888, to be followed by more than 160 contributions to periodicals, dealing with plants of all types and ages, as well as several important books. The first of these, his Sedgwick Prize essay on "Fossil Plants as Tests of Climate", opened up an interesting palæogeographical problem to which he made other valuable contributions later. Afterwards he devoted special attention to the floras of Mesozoic times, producing a series of British Museum catalogues (1894–1904) as well as studies on Mesozoic plants from all over the world. His text-book, "Fossil Plants", in four volumes (1898–1919), will long remain a standard work of reference. It contains a mass of information assembled from widely scattered sources and is a survey of the subject of great value to future workers. "Plant Life through the Ages" (1931) was a more concise study of the field with special reference to its bearing on some of the general problems of botany and geology.

In addition to books for specialists his facile pen produced several excellent semi-popular books, the last, a work on modern geology, being completed only two days before his death. With Sir Francis Darwin he edited "More Letters of Charles Darwin", and he edited a fine volume entitled "Darwin and Modern Science" for the jubilee of the "Origin of Species". He edited an interesting volume on "Science and the Nation" (1917) and acted as general editor of the Cambridge Botanical Handbooks and of other series produced by the Cambridge University Press.

The teaching and advancement of botany at Cambridge owes much to Seward's ability as a lecturer and administrator. He was appointed University lecturer in botany in 1890 and succeeded Marshal Ward as professor in 1906. At that time the Department of Botany was rapidly expanding, and the School continued to progress and expand throughout the thirty years of his professorship. A few years before his voluntary retirement from the chair he saw a notable addition to the laboratories built, equipped and opened. He was concerned in much useful reconstruction and reorganization in the Botanic Garden, which continues to be one of the finest University gardens in the world. He saw the Cambridge Botany School become a centre of research to which post-graduate students came from all parts of the world.

During many years Seward devoted part of his energies to college work. As fellow of Emmanuel and tutor from 1899 until 1906 he guided the studies of many who have made reputations as men of science. From 1915 until 1936 he was Master of Downing, a foundation noteworthy as a place of scientific education. His mastership marks an epoch in the history of the College, which not only maintained its scientific and legal traditions but also made great progress in literary and artistic studies.

Work as a professor and master led to many other administrative responsibilities in the University, to membership of many boards and syndicates, of the council of the Senate, and eventually to the office of Vice-Chancellor at a most important period. But all this did not prevent him from taking an active part in work outside Cambridge. Always a strong supporter of the British Association and often a member of its Council, he was twice president of Section K and in 1939 of the Association. Having been elected to the Royal Society in 1898 he served for two periods on its Council and was foreign secretary and vice-president from 1934 until 1940. He was awarded the Royal and the Darwin Medals. From 1922 until 1924 he occupied the presidential chair of the Geological Society, which awarded him the Wollaston Medal. He played a great part in the organization of the Fifth International Botanical Congress, over which he presided, and he was president of the International Union of Biological Sciences in 1931. He was chairman of the Scott Polar Research Institute and also of the Fenland Research Committee. After leaving Cambridge on his retirement in 1936 he spent much time in valuable work at the British Museum, of which he became a Trustee; he also became an active member of the Advisory Council for Scientific and Industrial Research.

One other lifelong interest must be mentioned that was probably connected with the liberal principles which he so strongly held. He thought that the knowledge of science and the interest which it contributes to life should be made available to many outside the older universities. He acquired much of his power as a lecturer at the outset of his career by delivering university extension lectures, and these courses had a very stimulating influence on the study of geology in the north of England. Later he became president of the Yorkshire Naturalists' Union, and took an active interest in the establishment of the University College at Hull. He was president of the Union of South-Eastern Scientific Societies in 1935, and of the Science Masters' Association in 1929. He worked for the establishment of a first-class journal of popular science, assisting in the management of *Discovery*, and contributing frequently to it.

Many well-merited honours came to Seward from academic bodies and scientific societies at home and abroad, and he was knighted in 1936. He had a singularly happy home life; his house was a place where many men of science have received a warm welcome and of which they have happy memories. Reminders of his genial personality remain in two excellent portraits in Cambridge, one in the hall of Downing College, the other in the Botany School.

H. HAMSHAW THOMAS.

Prof. J. S. Macdonald, F.R.S.

JOHN SMYTH MACDONALD was born in 1867. He was educated at King's School, Chester, and at Emmanuel College, Cambridge, where he took his B.A. (Math. Tripos) in 1889. In 1891 he was appointed Holt research fellow in physiology at Liverpool, and in 1897 he took the Scottish conjoint diploma in medicine. After qualification he was appointed assistant lecturer at Liverpool under Sherrington, who described the work of his Department during 1899 in the following terms: "The Department of Physical Physiology has . . . devoted most of its attention to the students, but Mr. J. S. Macdonald, the Assistant Lecturer in the subject, has also been engaged in active original research, the results of which, it is hoped, he will publish in an early number of these reports. Much work, however, has been spent in the preparation of systematic lectures, which have, indeed, been more of the nature of lecture demonstrations. The time spent has been very considerable, but now that the course with its experiments has once been arranged, it will require to be varied only in small details from year to year." The report adds that for the first time lady students had attended the classes: three ordinary students and one training for teaching. Among such men as Sherrington, B. Moore, O. Lodge and others Macdonald was fortunate in his colleagues.

The work to which Sherrington referred was published in 1902 and covered 135 large pages. It concerned "The Injury Current of Nerve". Using this as a test for the state of a nerve, Macdonald noted the changes produced in it by alteration of ions or of osmotic pressure in the surrounding fluids. By this work he took his place among the pioneers of British electrophysiology and physical chemistry applied to living tissues.

During the next few years, Macdonald published a series of articles in which he applied micro-chemistry to the investigation of nervous tissue. Using A. B. Macallum's cobalt method, he found that potassium was present not only at the point of nerve section and at the nodes of Ranvier, but also at any point where the nerve might be injured, for example, by drawing a hair tightly across it while it lay on the microscope stage. He investigated along similar lines the chloride distribution when mammalian or frog nerve was immersed either in solutions of different ions or of different ionic strengths, and he explained many previously mysterious histological findings. He showed that the axon fibrillæ were artefacts.

Macdonald began to apply the same methods to muscle, but was diverted (perhaps by its promise of scope for his mathematical powers) to the study of human energy exchanges. While professor of physiology at Sheffield he found the money with which to build there a human calorimeter room modified from the "Middletown calorimeter" described by Benedict. (This calorimeter was recently accepted by the Wellcome Medical Museum.) He set himself to study in turn the form of the curve of heat output in man during prolonged steady work on a bicycle; the relation during successive periods of work between a man's weight or his surface area and his mechanical efficiency, and finally the energy cost of different movements in work. After several papers had appeared in the *Journal of Physiology* and in the *Proceedings of the Royal Society*, Macdonald was elected a fellow of the Royal Society in 1917.

During later years Macdonald's health was unsatisfactory, and, though he retained a strong interest in the problems of muscular exercise, he gave most of his strength to the routine duties of his department. He had followed Sherrington as professor of physiology at Liverpool in 1914 and, on his retirement in 1932 at the age of sixty-five, he was appointed emeritus professor. For a time he lived near one of his sons who practised veterinary medicine in Lincolnshire, and more recently he moved to Bridge of Allan, where he died on March 29.

C. E. BRUNTON.

The Right Hon. Lord Austin, K.B.E.

BY the death of Lord Austin on May 23 at the age of seventy-four, the world has lost a great industrialist-philanthropist. As an industrialist, his name has become a household word which conjures up visions of the early small 'family' car; he was also a liberal benefactor of hospitals. Scientific workers, however, will also recall his munificent gift in 1936 to the University of Cambridge. His imagination, fired by the progress achieved by Lord Rutherford and colleagues at the Cavendish Laboratory, he gave the University approximately £250,000 for the development of the work of the Laboratory. Work on atomic physics had progressed to the stage, culminating with the demonstration by Cockcroft and Walton of the artificial disintegration of lithium, when it had become apparent that further advance involved the use of apparatus on an engineering scale. The University realized the need and also the desirability of improving facilities at the Cavendish in other ways, and had issued an appeal for a quarter of a million sterling, to which Lord Austin's gift was the splendid response.

The death of far-seeing captains of industry of the type of Lord Austin must always be a grievous loss to the world.

NEWS AND VIEWS

Royal Society of Arts: Albert Medallist

THE Council of the Royal Society of Arts has decided to confer on President Roosevelt the Albert Gold Medal of the Society in recognition of his prominent services to humanity as the fearless and resolute champion of the ideal of national freedom and individual liberty. The Albert Medal was struck in 1864 to commemorate Prince Albert's presidency of the Society during 1843–1861. It is awarded for "distinguished merit in promoting arts, manufactures, and commerce".

This award came very fittingly just in advance of President Roosevelt's declaration of a state of unlimited national emergency in the United States and of his long-awaited pronouncement on American policy in relation to the War. In effect, Mr. Roosevelt has now assumed powers which are as far-reaching as those wielded by the dictators of the totalitarian States, but with this significant difference; the dictators seized unlimited powers, whereas Mr. Roosevelt's mandate comes from the American people, who elected him president under a pledge that he would take all necessary measures to safeguard democracy in their country, and give all possible aid to the democratic nations now opposing Nazi aggression. He derives his powers from the people, who have voluntarily surrendered to him their liberties in the knowledge that the present crisis in world affairs requires swiftness and unity of action such as can be accomplished when authority is concentrated in the hands of the few; when the emergency passes with the suppression of Nazism, there are sufficient safeguards in a democratic community to ensure the effective restoration of individual liberty. The position of the United States is now similar to that in Great Britain. In his speech, Mr. Roosevelt re-affirmed the principles of democracy against the background of the story of Nazi oppression and intrigue, and asserted that freedom for the world goes with "Freedom of the seas". The United States will take all steps to provide supplies for the democracies, and will see to it that the supplies are delivered: "This can be done and must be done. It will be done."

Linnean Society of London: Gold Medallist

THE Gold Medal of the Linnean Society of London was presented to Prof. A. G. Tansley, emeritus professor of botany in the University of Oxford, at the anniversary meeting held on May 24. The Medal, which is awarded annually to "an eminent biologist as an expression of the Society's estimate of his services to science", is a fitting recognition of Prof. Tansley's contribution to ecology, and particularly to the development of the subject in Great Britain. The recent publication (1939) of his monumental work on "The British Islands and their Vegetation" rounds off an epoch in plant ecological work in Great Britain. The award of the Medal at this time thus seems particularly appropriate. Tansley's reputation as a fern anatomist was already made when, in 1904, he became one of the small group of enthusiasts, who, under the cumbrous title of the "Central Committee for the Survey and Study of British Vegetation", began systematic ecological work in Great Britain. His special contributions have been to the study of the vegetation of the English chalk. But his contribution to ecology has been far greater than his studies of particular plant communities. From the outset, Tansley was able to place his great gifts as editor and critic at the service of the committee. In 1902 he had founded a British botanical journal, the *New Phytologist*, as a private venture. For thirty years he owned and edited it. It was, and is, the avowed policy of the journal to open its pages to summaries of branches of botany "undergoing current rapid development". The British Vegetation Committee thus had a platform, controlled by one of its number, available for the discussion of concepts and principles upon which the new study should develop.

In the world of those days, international co-operation was possible. Tansley was one of those who realized the importance of personal contacts and frank discussion between the leaders of a new branch of science in different countries, if development was to proceed on right lines. He had much to do with the organization, in 1911, of the first International Phytogeographical Excursion, a memorable and ambitious tour of the British Isles, by a party of distinguished American and Continental ecologists. It was in this year, too, that Tansley edited and in large part wrote "Types of British Vegetation", a work that for many years was invaluable in interpreting British vegetation to botanists at home and abroad. When, in 1913, the British Ecological Society was founded, it was natural that Tansley should be its first president. It was not then expected that he should, in 1917, take over the secretary's work and editorship of the Society's *Journal*. This he did, and, for twenty-one years, Tansley, under his Council, guided the destiny of the *Journal of Ecology*. Its high standard, both in original papers and in critical articles and reviews, many written by him, owes much to his guidance. In 1926, Tansley was co-editor of "Aims and Methods in the Study of Vegetation", a work primarily published to foster ecological work in the Dominions and Colonies along right lines. In the preface to "The British Islands and their Vegetation" Tansley says that the work is largely "compilative". But the fact is that in this work, and throughout his long association with ecology in Great Britain, he has done much more than publish original work, or edit and weld the work of others. He has been the friend, critic and philosophic guide of most ecologists in Britain, and many overseas. That British ecology has in the main avoided some of the criticisms and rigidities of other countries is due in no small measure to Tansley.

Institute of Metals: Medallist for 1941

Dr. C. H. Desch, scientific adviser to the Iron and Steel Research Council, has been awarded the Institute of Metals Medal for 1941, "for distinguished services to non-ferrous metallurgy". It will be recalled that Dr. Desch retired from the post of superintendent of the Metallurgical Department of the National Physical Laboratory at the end of 1939 (see Nature, January 27, 1940, p. 34), after nearly forty years of active participation in metallurgical teaching and research, both academic and industrial. His professional work, however, was not allowed to suppress his early interest in chemistry, and he is the author of well-known books on the chemistry of cement and concrete, on intermetallic compounds and on the chemistry of solids; he has also taken part in the activities of the Institute of Sociology. The Medal of the Institute of Metals which Dr. Desch has now received is given every year and was presented to the Institute by the Mond Nickel Company; it is struck in platinum. Previous recipients of the medal have been Sir William Bragg, Sir Harold Carpenter and Dr. Paul D. Merica, a distinguished American metallurgist.

"I Married Adventure"

A film with the above title is shortly to be generally released throughout the provinces of Great Britain by Columbia Pictures, Ltd. It is a full-length travel film of a similar type to the now well-known "Dark Rapture". But whereas "Dark Rapture" was concerned with the lives, habits and customs of various tribes in the Belgian Congo, "I Married Adventure" deals with expeditions to Borneo and tropical East Africa, and is outstanding not for its photographs of tribal life, but for some quite unique animal scenes. These records were collected over a period of twenty-seven years by the late Martin Johnson and his wife, Osa, the producer of this film. In Borneo they have collected some remarkable shots of anthropoids, ones of particular interest being those of the golden gibbon. There are also some excellent pictures of the small honey bear.

In Africa, Mr. and Mrs. Johnson succeeded in photographing from an aeroplane some shots of animals which were being driven in search of water by thirst. These migratory movements of hundreds of elephants, with their accompanying heron flocks, wildebeeste, giraffes and zebras are shown so clearly that they are as thrilling as they are scientifically unique. The biologist will also be gripped by some interesting photographs of onyxes, with their attendant tick-birds, and specially by a combat to the death scene of two of these onyxes. Yet another outstanding scene is that of a flock of flamingoes packed so closely together in their positions on a lake that only the birds at the edge of the group are able to get sufficient run to be able to lift themselves off the ground with their wings.

This is a film that all biologists will want to see. It must be realized, however, that it contains several jarring features which would need to be overlooked. Many of the entertainment scenes are forced, prolonged and 'unfunny'; the introduction is awkward and unattractive, while technical production falls far below the height which Hollywood has taught us to expect. After seeing the film the biologist's heart will be further saddened when he thinks of the invaluable opportunities presented to Mr. and Mrs. Johnson to secure photographs which would throw light for many of us on the peculiarities of individual tribes. Apparently these opportunities were not taken. A book of the same title (pp. 376 + 71 plates. London and Melbourne: Hutchinson and Co. (Publishers), Ltd., 1940, 10*s*. 6*d*. net) has also recently appeared. People who have seen the film will want to read the book, and *vice versa*. Unfortunately, the book is of limited value to the naturalist. Objective descriptions of natural life are few in number, and the larger part of the book is given over to describing the emotional reactions of the author during her travels.

British Museum (Natural History): Recent Acquisitions

The late Dr. C. B. Ticehurst has bequeathed his important collection of birds to the Department of Zoology. The collection comprises more than seven thousand specimens, mainly from Spain, Portugal, Yugoslavia, North Africa, and north-western India. Mr. D. V. Burnett, of the Rezende Mines, Southern Rhodesia, has presented to the Department of Mineralogy a beautiful plate of crystallized gold, measuring 10 cm. × 9 cm. and ½ mm. thick. This is the largest of a number of similar plates which have been found in cavities along a fault plane at the Old West Mine, Penhalonga Alley, Umtali. The surface of the specimen shows stepped triangular elevations with the crystal form (311), some of which are capped with a crystal stud of silver. Other donations to the Department include montgomeryite and sterretite, two new phosphate minerals from Mr. A. Montgomery, of New York, and a fine set of celestine crystals from Peak Hill, Sidmouth, presented by Miss Lillias A. Cowan.

Eskimo Material Culture

Of recent years serious attention in Great Britain has been paid to the study of the way of life of the Eskimos. Expeditions have been made and material collected. In some cases excavations have enabled investigators to obtain a chronological sequence of industries. As a result the collections in not a few of our museums—the Museum of Archæology and Ethnology at Cambridge for example—have been considerably enriched and many of the finds are still in process of being studied. Naturally American and Canadian museums have not fallen behind in this respect, and a recent article (*Ann. Carnegie Mus.*, Feb. 18, 1941) describes a collection of about a thousand specimens gathered by Eskimos from old camp sites in the Belcher Islands in Hudson Bay and recently received by the National Museum of Canada.

Unfortunately little or no information is available about the circumstances of the finds so it is only possible to apply typological and technological methods of study. Here naturally the earlier work of Mathiassen has proved invaluable. It would seem that some of the objects must predate the historical period while others were clearly made after the introduction of iron to the district and cannot therefore belong to a period earlier than the middle of the sixteenth century and may well be a hundred years younger still. Influences from various outside areas are traced and comparisons made. The Eskimo culture has always had a special interest for prehistorians, for the conditions, and therefore the mode of life, of these arctic folk resemble to a considerable extent those obtaining in Magdalenian times. Comparisons, of course, cannot be pressed too far, but it is at least always helpful to have scientific descriptions and good illustrations of Eskimo implements.

Youth Welfare in Australia

REFERRING to the leading article entitled "Welfare of Youth" in NATURE of November 16, 1940, p. 627, Sir James Barrett, sometime chancellor of the University of Melbourne, and a well-known Australian occulist and surgeon, writes to say that in Australia the National Fitness Movement is getting well under way and relies on two organizations in the main for its efficiency, namely, the American Playground System and the municipalities, the latter item meaning decentralization. The American Playground System is now of vast proportion and aims not simply at physical efficiency but also at moral and mental development, since in competitive games rules are made and must be observed. In short, the aim is self-government.

But no playground in the United States or Australia, he writes, is of much service without trained playleaders who help to organize the activities and to enlist committees of parents who are taught what the movement means and how malnutrition can be avoided. In other words, the movement is a department in effect of the educational system. Dr. Gulick is the soul of the American movement, and those interested should read his work "The Philosophy of Play". The desire for play is innate in the animal kingdom, and is seen even in kangaroos. In human beings it is the mainspring which compels action, and it was the recognition of this fact that brought the modern playground into existence which, whilst originating in England, has been enormously developed and systematized in the North American continent.

Folk-Lore of Pulmonary Tuberculosis

IN a recent paper on this subject (*Tubercle*, **22**, 55; 1941), Dr. J. D. Rolleston states that while engaged in the composition of previous papers on the medical aspects of folk-lore (see NATURE, **143**, 111, 756; 1939) he had been struck by the numerous popular, as distinct from scientific, views concerning pulmonary tuberculosis. He had therefore collected the folk-lore of this disease, most of which was concerned with its prophylaxis and comparatively little with its ætiology and symptoms. As regards the ætiology it is noteworthy that long before it was held by the medical profession to be an infectious disease, pulmonary tuberculosis was regarded as such in some country districts in England as well as among the Karanja Indians and in Brazil. Among the causes of the disease in popular estimation were catching cold, inspiration of a very cold north wind, the sudden cure of skin diseases, especially scabies, and sexual excess.

The last factor accounted for the treatment by administration of the testes of a fox or chicken in folk medicine long before the introduction of endocrinology by Brown-Séquard. Dr. Rolleston classified the various folk-lore beliefs and methods in the prophylaxis and treatment of pulmonary tuberculosis as follows: (1) Transfer of the disease to other persons, animals and inanimate objects; (2) animal, plant and mineral remedies apart from any idea of transfer; (3) religious factors such as invocations to the Trinity, Virgin Mary and various saints, especially Pantaleon; (4) charms of different kinds, some of which dated from Anglo-Saxon times; (5) water in the form of drinking water or bathing in the sea, streams, wells and fountains; (6) one hundred and sixty-one miscellaneous remedies, such as the doctrine of signatures, the influence of the moon, odd numbers and mechanical methods.

Sources of Information on Agriculture

THE Association of Special Libraries and Information Bureaux is issuing a new series of revisions and expansions of sections of its Directory to be known as "ASLIB War-Time Guides to British Sources of Special Information". The first of this series "Fuel and Allied Interests" (excluding electricity) was issued last June. The second, entitled "Agriculture and Allied Interests", is now available ASLIB, 31 Museum Street, London, W.C.1. 5*s*. to members of ASLIB, 6*s*. to non-members). The Guide consists of forty mimeographed foolscap sheets and is divided into four sections. Section 1 summarizes the position of agriculture and describes the organization for agricultural education and research in time of war. Section 2 gives a list of sources of specialized information, indicating the nature of the work carried out and the publications issued by each body. Government and public departments, research organizations, agricultural colleges and university departments come into this category, together with professional and trade organizations and stock breeding societies. The third section provides a comprehensive list of periodicals and year books, those which print abstracts or lists of references being specified. The Guide concludes with a section consisting of subject indexes relating to both section 2 (sources of information) and section 3 (periodical publications). Compilation has been carried out in close collaboration with specialist advisers, and the details concerning the individual organizations have been supplied by the latter themselves.

Forestry in New Zealand

The annual report of the State Forestry Service of New Zealand, drawn up by Mr. Alex. R. Entrican, director of forestry, is a concise document dealing with various forest activities. The great value of the report lies in the attention it directs to the position of the very large area of exotic plantations existing in the country and the difficulties facing their treatment. "A timber famine scare", says the author, "in all English-speaking countries was one of the products of the Great War, and it was perhaps inevitable that under the existing conditions of those times extensive tree-planting with quick-growing exotics should follow. Employment was required for large numbers of repatriated soldiers; then mass-production psychology, born out of munitions and automobile manufacture, favoured large-scale forestry operations. To some degree extensive areas had been planted with unsuitable species or consist of soil fit for neither agriculture nor forestry. The former has often been due to the impossibility of obtaining the amounts of suitable seed required in the general large scramble to plant."

The most serious result, however, is connected with neither of the above. This urgent large-scale planting has been the creation of 750,000 acres of plantations with complete disregard for the essential necessity of creating well-distributed age classes. For example, three State exotic forests totalling 41,000 acres were 91 per cent planted during the five-year period 1927–31. During the same period more than 80 per cent of the total State *insignis* pine stands were planted, and more than 50 per cent of the privately owned stands. It will be obvious to any forester that the correct management of this enormous area of almost even-aged forests is going to prove a difficult problem. As the director of forestry correctly says, only by intensive planning and organization may enormous losses be avoided in these medium-age classes which form such a large proportion of the exotic forest resource. A future better distribution of age classes is obviously an aim. To assist, a recommendation is made that for the present all fellings in indigenous forests should cease.

"Kill Statistics" from California

Game birds and animals form a valuable food resource of any country, but the permanent value of the resource depends upon the skill with which it is at once utilized and husbanded. In California the control of game is supervised by the Division of Fish and Game, and in order that effective regulations may be made it is essential that the Division should know how many individuals of each species are killed in the various parts of the State. In one area a species may be abundant in spite of the sportsman, in another it may require further protection. The method of collecting the information upon which legislation depends is by questionnaire, attached to hunting licence application forms, and the experts are convinced that the returns give a reasonably accurate tale of the slaughter. The statistics for 1938 have been published by J. I. Hunter and Donald H. Fry, jun. and reveal some astonishing numbers (*California Fish and Game*, **26**, 310; 1940). The estimated number of ducks killed was 950,000; geese, 90,000; pigeons (Columba), 95,000; doves (mainly Zenaidura), 1,700,000; quail, 1,500,000; pheasants, 125,000. The mammal numbers are also very considerable: cottontail and brush rabbits, 500,000; jack rabbits, 750,000; deer (two species), 35,045. In 1939, 43,251 deer were killed, a number strongly in contrast with the moderate slaughter of twenty-five years ago, when the estimate of killed reached only 12,000.

Caffelite: a New Plastic

For many years excess production of coffee has been a serious problem for the Brazilian Government; thousands of bags have been deliberately destroyed every year to prevent them coming on the market. Now that markets in Germany, Italy and other European countries are lost to them, the position is even more serious. According to the *Electrician* of April 18, an investigation conducted in New York has led to the discovery of a new plastic material, which is known as 'Caffelite', and industrial plants will come into operation in Brazil this year in which at least part of the excess supply of coffee will be absorbed in the manufacture of Caffelite. The product is said to have useful electric properties at low frequencies. The material is moulded under pressure of one or two tons per square inch, and has a specific gravity of 1·43, that is, about ten per cent higher than wood flour filled phenolic moulding materials of the 'Bakelite' type. The other physical properties are stated to be similar to those of 'Bakelite', and it is claimed that all colours can be produced except white.

Engineering Construction in India

In *Engineering* of April 4 there is an article on a welded water main in Burma which gives an interesting illustration of the growing self-sufficiency of India and Burma from the point of view of engineering construction. Forty-three miles of water main 4 ft. 10 in. in diameter were required for the city of Rangoon. The steel plate was rolled by the Tata Iron and Steel Co. Ltd. at Jamshedpur, and shipped to Rangoon, where the fabrication was effected by Messrs. Braithwaite, Burn and Jessop Construction, Ltd. The main was made in lengths of 25 ft., each length of pipe consisting of three plates in the circumference, the plates as rolled being 62 in. wide by $\frac{7}{16}$ in. thick. After the plates had been bent to one-third of a circle, each set of three was assembled in six rigid rings spaced equally along the length of the pipe and supported on rollers. An automatic carbon-arc welding head, of the 'electronic tornado' type, mounted on a small carriage, was then run along the longitudinal seam at the bottom of the assembly and the pipe rotated for the welding of the two remaining seams in the same position. The inside seams were butt-welded. They were not completely welded from the inside only, a second run on the outside surface of the pipe with an automatic carbon-arc welding-head being required to complete them. The fabrication of this water main necessitated the employment of 500 men, all but ten of whom were native workers. It is noticeable that the time taken for completing the contract was six months shorter than the scheduled time, this being due to the adoption of welding for the construction.

Earthquakes in Spain

Two earthquake shocks caused some slight damage at Jativa, in Valencia, Spain, on May 23. No casualties are reported. Slight earthquake shocks are fairly frequent in southern Spain, which is part of the seismic zone stretching from the Atlantic Ocean at least to Turkey through the Mediterranean.

The Night Sky in June

On or about June 21, the date of the summer solstice, the nights in the latitude of London last barely 7½ hours, if reckoned from sunset to sunrise; but nautical twilight (sun not more than 12° below the horizon) reduces the duration of actual darkness to about 3 hours. Nautical twilight lasts all night throughout the month in Lat. 56° N. Conditions for scanning the night skies this month are therefore much restricted. The moon is full on June 9 at 12·6h. and new on June 24 at 19·4h. Mercury may be seen in the evening twilight this month, greatest elongation of 24° east being reached on June 6. Venus is also an evening star and is in conjunction with Mercury on June 20. Telescopic views will show Mercury as a diminishing crescent and Venus as nearly full in phase. Mars rises in the early morning and is 5° above the eastern horizon soon after 1h. 30m. at the beginning of June and before 0h. 30m. at the end of the month. (All times are given in Universal Time; add 2 hours to convert to Midsummer Time.) The brightness of the planet is increasing; conjunction with the moon occurs on June 16. Saturn is a morning star, low in the east before sunrise; and after mid-June Jupiter comes likewise into view. Saturn is in conjunction with the waning moon on June 21 and Jupiter on the following day.

Portrait of H. E. Armstrong

The first Armstrong Memorial Lecture was delivered by Dr. E. F. Armstrong on February 3. The complete Lecture was published in *Chemistry and Industry* of February 8, and included a striking photograph of "H. E. A." in holiday mood, taken by Mr. Edwin Thompson on board ship between Vancouver and Victoria after the Winnipeg meeting in 1909 of the British Association. Mr. Thompson has a number of photogravure reproductions of this portrait which he is willing to give free of charge to anyone interested; requests should be made to him at Speke Hall Road, Liverpool, 19.

Announcements

At the anniversary meeting of the Linnean Society, held on May 24, the following were elected officers for the year 1941–42: *President*, Dr. E. S. Russell; *Treasurer*, Major F. C. Stern; *Secretaries*, Mr. I. H. Burkill (botany), and Dr. Malcolm Smith (zoology); *New Members of Council*, Dr. B. Barnes, Prof. F. T. Brooks, Mr. J. E. Dandy, Mr. A. C. Gardiner and Mr. Douglas M. Reid.

The Carnegie Corporation of the United States has granted the Society £2,000 for the purpose of photographing the manuscripts and natural history specimens in the collections of Linnæus.

At the annual general meeting of the Royal Sanitary Institute the Earl of Bessborough was elected president in succession to Lord Balfour of Burleigh, whose period of office had expired.

The late Dr. Charles Slater has left £4,000 to the University of Cambridge for teaching or research work in medical science or any science ancillary to medicine at the discretion of the University.

Dr. W. G. Woolnough, geological adviser to the Federal Government of Australia, has retired from the Commonwealth Public Service after thirteen years service and has been succeeded by Dr. R. W. Raggatt, of the Commonwealth Geological Staff.

There will be an exhibition of maps, plans and panoramas of London from the sixteenth century until to-day at the Royal Institute of British Architects, 66 Portland Place, W.1, during the period May 29—June 21, between the hours of 10 a.m. and 6 p.m. (Saturdays, 10 a.m. and 1 p.m.); admission free. The opening of the exhibition will coincide with a lecture on the planning of London, which Mr. W. H. Ansell, president of the Institute, is giving at the Royal Institution on May 29. The exhibits have been drawn mainly from the Institute's own collection; as a precautionary measure, the earlier maps and panoramas will mostly be represented by facsimile copies made by the London Topographical Society.

War has again inflicted severe losses on the University of Louvain. Numerous University buildings were destroyed during hostilities, including the library rebuilt by American generosity and restocked by gifts from nearly every university in the world. Of its 900,000 volumes 15,000 only remain intact, and of its 800 manuscripts only 15 are left.

The Glass Manufacturers' Federation has recently established, for the duration of the War, a Defence Advisory Panel, to advise on scientific, technical and allied problems relating to glass which may arise as the result of contacts between Service or other Government Departments and the Federation. Its members are: Prof. W. E. S. Turner (chairman), Dr. B. P. Dudding, Dr. W. M. Hampton, Dr. H. Moore, Mr. J. B. Murgatroyd, Dr. C. J. Peddle and Dr. E. Seddon. Communications for the Advisory Panel should be addressed to Mr. Geoffrey Marchand, director of the Glass Manufacturers' Federation, Orleans, Latimer Road, New Barnet, Herts.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

IN THE PRESENT CIRCUMSTANCES, PROOFS OF "LETTERS" WILL NOT BE SUBMITTED TO CORRESPONDENTS OUTSIDE GREAT BRITAIN.

Diffuse Reflexion of X-Rays

I WISH to add some remarks concerning the theory of the new effect described by G. D. Preston in his article published under the above title in NATURE of April 19, p. 467. A critical study of the suggestions brought forward by Sir C. V. Raman and Sir William Bragg showed that they cannot be accepted as possible explanations, and some photographs kindly sent to me by Mrs. Lonsdale convinced me that the effect ought to be a consequence of Debye's well-known theory of the influence of thermal vibrations on the scattering of X-rays. As the literature on this subject, although extended, is not satisfactory, I have (in collaboration with Miss K. Sarginson) reconsidered the problem assuming that the scattering power of each single atom is known, and only the influence of the atomic vibrations is to be determined.

Apart from the effect on the intensity of the Laue spots (treated by Debye, Waller and others), there exists a background scattering given by an expression which is not an average over the vibrations (as specific heat is) but depends explicitly on their amplitudes and frequencies. The expressions are rather complicated. In order to simplify them we have assumed that the vectorial waves of atomic vibrations can be approximately replaced by scalar waves. Even then the formula is too complicated to be written down here. It gives a definite intensity distribution of the scattered light for any direction of the incident beam relative to the crystal. It depends, apart from the universal constants, h, k, c, on the wave-length λ of the X-rays and some properties of the atoms and the lattice: the lattice constant, the atomic weight and the function $\omega(\mathbf{q})$ representing the elastic frequencies as a function of the wave vector $\mathbf{q}$. In fact, the intensity is in this approximation a monotonically decreasing function of this $\omega(\mathbf{q})$; therefore the maxima of intensity coincide with the minima of $\omega(\mathbf{q})$.

This result explains most of the features which have been discussed in connexion with the extra spots. The first point is the fact that each extra spot is associated with a Laue spot which it passes when the crystal is rotated, with rapidly changing intensity (increasing for approach to the Laue spot). Indeed, the Laue spots are given by the absolute minima $\omega(2\pi\ ) = 0$ ($\mathbf{h} = (h_1\ h_2\ h_3)$ three integers), which occur only for definite relative positions of crystal and incident ray. If the crystal is rotated the wave vector $\mathbf{q}$, as argument of $\omega(\mathbf{q})$, has to satisfy the relation

$$\mathbf{q} = \mathbf{K}' - \mathbf{K},$$

where $\mathbf{K}, \mathbf{K}'$ are the wave vectors of the incident and scattered beam. If $\mathbf{K}$ is given, $\omega(\mathbf{q})$ is a function of $\mathbf{K}'$ which has relative minima: these are the centres of the extra spots. This result, that the position of the spots is closely connected with the vibrational spectrum of the crystal, is very remarkable. It leads immediately to an understanding of the success of Sir William Bragg's formula. I cannot accept Preston's and Bragg's suggestion that there exist little groups of atoms (such as Bragg's cubes) which scatter independently of the rest of the crystal. This explanation is based on the assumption that the interference effects are due to the *geometry* of the lattice. In fact, these new interferences, which depend on temperature, are due to the *dynamics* of the lattice. One has merely to assume that the forces between the atoms are negligible except for first neighbours; then $\omega(\mathbf{q})$ becomes a periodic function in the reciprocal lattice of the very type from which Bragg derives his formula. We obtain precisely Bragg's formula for a body-centred cubic lattice, and very similar ones for other cubic lattices. But we get in addition a reasonable law for the intensity as a function of temperature which cannot be obtained by any purely geometrical explanation.

We have also studied in detail the behaviour of the extra spots in the neighbourhood of a Laue spot h, with the help of a development in powers of $\varphi - \varphi_h$, the angular displacement of the crystal from the position corresponding to a Laue spot. If the direction of the incident beam is taken as x-axis, and the crystal is rotated about the y-axis, we obtain for the direction cosines ξ, η, ζ ($\xi^2 + \eta^2 + \zeta^2 = 1$) of the scattered beam

$$\begin{cases} \eta - \eta_h = \eta_h \xi_h (\varphi - \varphi_h) \\ \xi - \xi_h = (\zeta_h{}^2 + \xi_h - 1)(\varphi - \varphi_h), \end{cases}$$

where ξ_h, η_h, ζ_h is the direction vector of the Laue spot. These formulæ are purely geometrical and give no information about the physical mechanism. The same holds for the formula giving the angle χ between the extra ray and the Laue ray, for which one obtains

$$\chi = 2 \sin^2 \frac{\theta_h}{2} (\varphi - \varphi_h)$$

where θ_h is the deflexion angle of the Laue spot, which has been derived by several authors (Faxén, Raman, Jauncey, Preston, Lonsdale) on different assumptions.

The physical assumptions of the theory can be tested only by a discussion of the expression obtained for the intensity distribution. We have determined the shape of the spot, that is, the lines of equal intensity; they are ellipses the minor axes of which coincide with the meridian passing through the Laue spot. We have further calculated the maximum and the total intensity of the extra spot; these depend on the neighbouring Laue spot, on the temperature, the wave-length of the X-rays, and the constants of the crystal, chiefly the maximum frequency ω_m of the elastic spectrum, or the corresponding temperature $\theta = h\omega_m/k$. All results are in qualitative agreement with the observations.

Free Aryl Radicals in the Fittig and Ullmann Reactions

Hey and Waters[1] have given a valuable review of some organic reactions involving the formation of free radicals in solution. From this and from later work two properties stand out among others as being characteristic of free aryl radicals in solution. One of these is the persistence with which such radicals remove hydrogen from all solvents containing non-aromatic hydrogen, and so become converted to the corresponding aryl hydrogen compounds; and the other is the displacement by them of hydrogen from aromatic liquids to yield biaryls, the substitution occurring invariably *ortho* and *para* to substituents in the benzene ring, irrespective of their nature.

In a series of Ullmann, Fittig and related reactions carried out recently in this laboratory, it was consistently observed that one of the products formed on treating ArX (X = Cl, Br, or I) with sodium or copper was the corresponding aryl hydrogen compound ArH. It seemed probable that this was a result of the formation of free aryl radicals in the reaction, and that ArH was formed from these either by reaction with the diluent (ether), where this was present, or by dismutation when diluent was absent[2].

In order to obtain confirmation of this view, iodobenzene was caused to react with copper bronze in a sealed tube in the presence of an excess of ethyl benzoate, when it was expected that free phenyl radicals if formed would displace hydrogen from the *ortho* and *para* positions in the ethyl benzoate. The product of the reaction was boiled with caustic alkali, and neutral material was separated by ether extraction. On acidification of the alkaline solution a mixture of acids was obtained, in which diphenyl-2-carboxylic acid and diphenyl-4-carboxylic acid have been shown to be present. The latter was easily separated in a pure condition by fractional recrystallization, and the former, which was more difficult to purify, was shown to be present since fluorenone could be isolated from the reaction mixture after treatment with sulphuric acid. No evidence was obtained for the presence of any other components in the mixture.

The isolation of these substances is strong evidence for the formation of free radicals as intermediates in this reaction, and it and allied reactions are under investigation from a similar point of view. The results will be recorded elsewhere.

Respiration of Leguminous Root Nodules

A PREVIOUS communication from one of us (G. B.[1]) referred to observations on the rate of evolution of respiratory carbon dioxide from leguminous root nodules still attached to the plant. Those observations have been extended and are being published elsewhere. A brief report is presented here of other observations (which will not be continued at present) on detached nodules, made by means of a respirometer designed by one of us (G. F. A.). This apparatus provides concurrent records of oxygen intake and carbon dioxide evolution and is being described in another publication. It is our belief that the only complete figures for the respiratory gaseous exchange of nodules so far published are those of Allison and his collaborators[2,3], though recently Wilson[4] has recorded observations on oxygen intake. Information concerning respiratory events within the nodule will contribute to an increased understanding of the general metabolism of the nodule, including the process of nitrogen fixation.

The observations were made at a temperature of 25° C. on nodules taken mostly from Manchu soya bean plants growing in solution culture. During the determinations the nodules usually were kept moistened with the inorganic nutrient solution in which the plants had been grown. All figures quoted refer to c. mm. oxygen absorbed or carbon dioxide evolved per hour per mgm. dry weight of tissue. In twelve experiments with nodules of various sizes from soya bean plants inoculated with Wisconsin strain No. 505 of the nodule organism, values ranging from 2·31 to 6·25 were obtained for oxygen intake. Using nodules from field-grown soya bean plants, Allison *et al.*[2], at 28° C., obtained lower values for oxygen intake in air (range 0·76–2·05), while Wilson[4] reports a value of 1·53 for nodules from plants infected with strain 505. Allison *et al.* observed that the respiratory quotient was well above unity for nodules respiring in air, the range for soya bean nodules being 1·23–2·00. Partly because of this type of result they concluded that partially anærobic conditions prevail within nodule tissues. In our material also the respiratory quotient was usually greater than unity (range 1–1·25). For detached younger parts of the roots of the same soya bean plants, values of 1·70–2·17 were obtained for oxygen absorption, with quotients very close to unity. The rate of respiration of the roots was thus inferior to that of the nodules, whereas Allison *et al.*[3] concluded that in their material root and nodule respiration were of the same order. Wilson[4], on the other hand, observed root respiration to be considerably in excess of nodule respiration. It thus appears that the intensity of respiration within leguminous nodules and roots is liable to vary in material from different sources.

Contrary to the experience of Allison *et al.*[2], in our material of soya bean nodules no definite tendency was detected for the respiratory quotient to be higher in larger nodules than in smaller ones, though observations on this point were not extensive. Nodules from plants infected with an ineffective strain of the nodule organism (No. 507) showed much lower rates of respiration (oxygen absorption 0·7), though the respiratory quotient was similar to that characterizing nodules in which normal fixation was proceeding. For pea (*Pisum sativum*) nodules figures of 1·89–3·24 were obtained for oxygen intake, the respiratory quotients ranging from 1·05 to 1·25. In all these observations the respiration measured is, of course, due partly to the plant tissues of the nodule as well as to the bacteria.

Publication of New Species

ONE of the inevitable results of the War is a reduction in the output of pure scientific literature. This enforced breathing-space seems an excellent opportunity for scientific workers in general, but systematic zoologists in particular, to assail the problem of the scattering of the literature.

In year 1935	Number of publications other than books	Number of journals used	Number of authors	Authors publishing single paper during the year	Authors who publish more than one paper and confine publication to one journal only	Journals publishing one paper only devoted to the one group of animals in question	Journals entirely devoted to one group in question	Number of new species described in the year	Number of journals in which these new species are described	New species described in purely medical journals
Protozoa*	940	263	605	441	48	150	3	549	83	9
Mollusca	1117	376	698	528	56	184	7	1437	139	Not checked; probably none
Helminths (including medical literature)	1400 (392 medical)	451 (166 medical)	1191	1037	55	287	3	776	112	34
Siphonaptera (Insecta)	19	17	15	14	1	15	0	15	5	1
Aves	1662	388	1043	769	93	203	39	230†	39	Not checked; probably none

* These groups are not comparable as entities, and include fossil species.

† Sub-species as well as species.

Probably only systematists are aware of the extent of this scattering. The output is considerable (Salt points out that 10,000 new species of insects are described every year), but nevertheless a disproportionate amount of time is spent 'grubbing' in the library. Who has not groaned over obscure periodicals, such as the *Acta Univ. Latv.*, the *Est. de Sci. Habana* or the perennial *Igakkai Zasshi* ?

The table above shows an analysis of the literature of a twelve-months' period chosen at random, and relating to five groups of animals, also chosen at random. No comment is really necessary, but one or two points may be emphasized :

(*a*) The number of journals which, during the year, print only *a single* paper dealing with any one of the groups in question ;

(*b*) The low percentage (20 per cent) of authors publishing more than one paper during the year, who confine these to one journal ;

(*c*) The scattering of descriptions of 776 new species of helminths through 112 journals.

The causes of this literary diaspora are diverse and numerous. Authors, for example, may desire to publish several papers simultaneously, or obtain plates to illustrate them all, or to increase the circle of their readers, or to achieve priority by rapid publication in some modest journal without a waiting list. Financial considerations, on the other hand, prohibit the production of many journals devoted to single groups, except in cases of special popularity, such as we find in the class Aves. Institutes which publish their own journals must include widely divergent contributions. Editors, with an eye to the standard of their publication, its circulation and limited resources, look upon short papers with favour and encourage 'variety'. There are also geographical, nationalistic and linguistic groupings. Nevertheless, however diverse the legitimate and non-legitimate reasons for the scattering may be, the fundamental underlying cause is the total lack of any real system associated with the publication of scientific literature.

Perhaps it is over-sanguine to dream of international co-operation at the present moment, but even co-operation on a small scale between editors in any one country might lay the foundation for more ambitious and far-reaching schemes.

A little judicious exchange would eliminate those cases of journals printing, for example, one helminthological paper a year, and render impossible specific zoological descriptions of new species appearing exclusively, for example, in *Arch. Experimental Medicine*. For institutions, a more widespread application of the system of publication of the American Museum might also be advocated.

We hear much from politicians on the subject of post-war reconstruction. Surely the systematic zoologists will seize this unequalled opportunity for turning the present loss of time into future gain ?

MIRIAM ROTHSCHILD.

Ashton Wold,
Peterborough.

Decipherment of Charred Documents

THE large number of hand-written documents, such as deeds, accounts and ledgers, which have recently been damaged or destroyed by fire has inevitably directed attention to methods of deciphering charred documents, and the description of a simple photographic method recently found successful in these laboratories may be of interest. The documents on which most of our experiments have been carried out were burnt completely black, but were fairly resistant to handling and showed traces of the writing in relief on the surface. No results were obtained by ordinary photographic copying methods with oblique lighting, with infra-red or ultra-violet radiations, or by the chloral hydrate method described by Messrs. Taylor and Walls of the Metropolitan Police Laboratory at Hendon[1].

The method depends on exaggerating photographically the difference between the specular reflectivity of the remains of the plain paper and of the ink. Essentially, the charred paper surface can be regarded as a mirror the surface of which can be made to reflect an intense source of light close to the camera lens and on which the original writing stands out as a dark shadow, presumably due to the disturbance of the paper fibres by the pen and to the presence of some residual salts from the ink. This shadow is photographed by the use of a high contrast blue-sensitive plate such as the Kodak *B* 5.

In practice, it is first necessary to render the charred sheet absolutely flat. With the more robust of the specimens, this is easily possible in a pressure printing frame. If the pressure is applied evenly and fairly slowly the sheet does not tend to crack up. It has been found satisfactory to press more fragile specimens gently on to the damp surface of a gelatin-coated glass sheet, such as a fixed-out and washed photographic plate, and then to apply pressure in the frame.

The most suitable lighting has been found to be a small arc lamp close to the camera with a lens so arranged that it throws a narrow beam of light on to the copy. This gives the required illumination and, in conjunction with a long-focus lens on the camera, the optimum type of reflexion into the lens from the surface of the document. It is well known that differentiation between specularly and diffusely reflected light can be increased by the use of polarizing screens over the camera lens, but so far this additional step has not been found necessary for successful deciphering of the documents we have examined.

No claims are made for the infallibility of the method described, and, in fact, it is probably practical only with a fairly limited number of combinations of ink and paper, but, as it has been found to work excellently in some cases where all the methods described in the literature have failed, we feel that its publication may be of use to other workers.

"The Man of Science as Aristocrat"

LIEUT.-COLONEL MOORE-BRABAZON has fallen into a common error of thought when he says that a politician who ensures a milk supply deserves more of his fellow men than does the inventor of the quantum theory[1]. The boy who posts a lighted squib in a pillar box commits the same offence whether the pillar box is empty or is filled with an unusually important mail. The fact that an action does not seem to the majority to be of immediate consequence is no guide to its importance. Colonel Moore-Brabazon's hypothetical politician will be deserving of the severest censure if he does not ensure the necessary milk supply, provided always that he is aware that our state of mechanical and scientific development is such as to make it possible; he deserves no credit for doing what is simply his job.

Our difficulties lie in the provision of such gifted public servants. Many of those we now have, by their lack of a scientific background, are unaware that the solutions of their problems exist, and in some instances there is even a suspicion that the existence of the problem itself goes unnoticed. The imperative need for men of science with a responsibility in public affairs, in a social system which has changed out of recognition in a period measured in months, is not at all appreciated.

It is true that, "in the narrow world of science" the inventor of the quantum theory gets more attention than the average run of politicians do; but it must also be pointed out that the man of science who enters the public service is left in no doubt of the inferiority of his position compared with that of his lay colleagues. In consequence of this, cases are known of young men with the foundation stone of scientific knowledge laid at their universities who have seen the financial folly of building a superstructure of experience thereon, and have deliberately concealed their degrees in science in order to taste the fleshpots of an 'administrative' post which could be filled by an intelligent clerk. Such a man is a waste of material, since it is only by the practice of science over a period of years that he gains a knowledge which is likely to be useful to his fellow men. By that time an attempt to 'come out of his shell' is usually out of the question on account of his age and lack of 'administrative' experience, for he will naturally prefer to remain in his shell rather than enter a new field as a junior.

Reservation of Librarians

I SHOULD like to direct attention to a serious defect in the Schedule of Reserved Occupations just issued by the Ministry of Labour. While the librarians of newspapers, periodicals or news agencies are reserved at the age of thirty-five, the librarian of a university, public or research institution library is not reserved at all. General clerical staffs of universities and municipalities are also reserved at thirty-five, and it would therefore appear that the importance of what to every scientific worker is a vital tool—a well-selected and organized library under competent direction—is not realized by the Ministry.

NATURE has from time to time given space to notes about the pioneer work of the Science and Technology Department of the Sheffield City Libraries, particularly in regard to the organization of the interchange of technical information between research libraries in the Sheffield area. This Library may be used as an illustration of the unwisdom of the Ministry's decision. Since the War began, the Science and Technology Library has issued more than forty bibliographies dealing with specialized aspects of steel making and steel treatment. Requests for copies of these bibliographies have been received from scores of important industrial establishments, both at home and overseas, which maintain research staffs, and copies of some of them are being prepared for distribution by the Ministry of Supply. It would seem reasonable to suggest that the librarian of a library of this type, which can be paralleled by similar special public libraries in other great cities, should be held to contribute as much to the promotion of the War as a routine clerk in other departments of the municipal service.

J. HAWNT,
Chairman of the Libraries, Art Galleries
and Museums Committee, Sheffield.

We believe that the principal purpose of the Schedule was to obtain postponement of the calling-up of whole groups of people. In addition, an employer may apply for the deferment of the calling-up of an individual who is personally indispensable, and each such case is considered on its individual merits. In view of the high proportion of librarians for whom reservation will no doubt be justly claimed, it would seem that qualification of the Schedule definition is desirable.—Editors of "NATURE."

RESEARCH ITEMS

Breeding-Place of Ross's Goose

Ross's goose, *Chen rossi*, has many associations with the Hudson's Bay Company. One of its officers recorded it in 1795, in 1861 it was named after the officer at Fort Resolution, and now in 1940 the support of the Company and the energy of its representatives have solved the mystery of its breeding-place (P. A. Taverner, *Canadian Field-Naturalist*, 54, 127). This small goose, scarcely larger than a mallard duck, used to be abundant about Lake Athabasca and Great Slave Lake, where so many were killed and salted for winter food that fears have been expressed for its survival. But until now nothing has been known about its breeding haunts, and the only egg in existence was one laid in captivity. In 1940 the Hudson's Bay Company authorized an expedition for the express purpose of solving the problem, and guided by promising native reports the explorers, two managers of the Company's posts and four Eskimos with a canoe on dog-sled, pushed up the Perry River which flows into Queen Maud Gulf close to longitude 102° West. Up a tributary of the Perry they reached an unnamed lake—the country is unexplored and unmapped—where large numbers of Ross's geese were seen. The lake was studded with two or three hundred islets, and on these the white geese were nesting, looking at a distance like ptarmigan in winter plumage. The nests, sometimes within three feet of each other, were about a foot across, lined with down, and contained from two to six creamy-white eggs. Natives reported that the chief breeding-grounds were on an island in a larger lake about six miles away, and they reckoned that about two thousand would be nesting there.

Termite Investigations in Australia

Two species of mound-building termites, namely, *Eutermes exitiosus* Hill and *Coptotermes lacteus* (Froggi) have been the subjects of several investigations carried out under the ægis of the Council for Scientific and Industrial Research for Australia. Two papers, by F. J. Gay and J. Greaves, which deal more especially with the last-named species, have recently been published (*J. Coun. Sci. Ind. Res.*, 13, No. 2; 1940). The first paper is concerned with analyses of the populations of two colonies of *C. lacteus*, and is complementary to an earlier paper dealing with the population of Eutermes colonies. Coptotermes, it may be added, is the genus responsible for most of the damage incurred by termites in Australia. The estimated populations of two colonies of the species *C. lacteus* amounted to 600,000 and 1,100,000 individuals respectively, with a caste ratio of 86–92 per cent of workers, 6–7·5 per cent of reproductive nymphs and 2–3 per cent of soldiers. Compared with *E. exitiosus* the proportion of soldiers is much lower in *C. lacteus*, whose whole population is also rather less. In a second paper in the same issue of the journal already named, the authors discuss the subterranean foraging galleries which radiate from the central mound or nest of *C. lacteus*. Some fifteen main galleries were found to branch in a manner that causes them to extend over an area of approximately 1½ acres. These galleries enable the termites to reach logs or pieces of dead wood, which provides their staple food. Such logs may be up to 50 yards distant from the central mound. In each of two other mounds, located in a different type of habitat, the foraging galleries were more than thirty to a nest. While these galleries may lead with reasonable directness to neighbouring logs, their detailed meanderings en route indicate that such passages rarely point in the actual direction of the logs with which they become ultimately connected. It is concluded that the termites in question do not possess any mysterious sense of direction which some observers may be inclined to attribute to them.

British Water Bugs

We have recently received Scientific Publication, No. 4, of the Freshwater Biological Association of the British Empire. The work in question is entitled "A Key to the British Water Bugs", 1941, and is written by T. T. Macan. In the small compass of thirty-six pages is included sufficient information and illustrations to enable all British aquatic Hemiptera-Heteroptera, excluding the Corixidæ, to be readily identified. Notes on the biology and distribution of the various species are included, together with a list of the more important original papers bearing upon the subject. For the Corixidæ the reader is referred to a previous publication issued by the Association. It is noteworthy that the last comprehensive work on British Heteroptera, which included the aquatic forms, was that by Butler, published in 1923. Since that time recent work has made this volume somewhat out of date in so far as the grouping of the members of Notonecta are concerned, while the addition of a species of Hydrometra and of two species of Microvelia to the British fauna have to be noted. These and other features are dealt with in Dr. Macan's brochure, which is obtainable from the Association at Wray Castle, Ambleside, Westmorland, price 1*s*. 6*d*.

Microsporophylls of Caytonia

A reinvestigation by Prof. T. M. Harris (*Ann. Bot.*, N.S., 5, No. 17; Jan. 1941) of the microsporophylls of Caytonia greatly strengthens the evidence for associating the Caytoniales with the Pteridosperms rather than with the Angiosperms. In construction and mode of dehiscence the Caytonanthus synangium is wholly unlike any flowering plant anther, while the leaf-like branching and dorsiventral structure of the whole sporophyll is equally remote in morphology from any Angiosperm stamen. The synangia of some fossil Marattiaceæ and Pteridosperms, however, show much closer resemblances to Caytonanthus which also shares with some Mesozoic plants of Pteridospermous affinity the winged pollen grains which mark it off from all known Angiosperms. A critical re-examination of the pollen grains leads to the recognition of another species of Caytonanthus, *C. oncodes*, which differs from *C. Arberi* in the dimensions of the pollen grains. The former is referred to *Caytonia Sewardi* which it pollinates while the pollen in the micropyles of seeds of *Caytonia Nathorsti* is referred to *C. Arberi*.

Banana Leaf Disease

RECOGNITION of the fact that the leaf spot disease of bananas (*Cercospora musæ* Zimm.) in Jamaica is likely to remain, has directed attention to the need for securing control at minimum cost. Spraying with copper-containing fungicides has been found to give good control, but under Jamaica conditions is liable to prove expensive, tedious and, on much of the land under cultivation, difficult. It is therefore necessary that simple and economic means of securing adequate control should be sought. Recent investigations by R. Leach (Bull. 26, Dept. Sci. and Agr., Jamaica, 1941) have been undertaken with this end in view. As elsewhere the heart leaves are most subject to infection. A curious feature noted by Leach, as also by other investigators, is that while spraying gives good control, the waxy heart leaves are, nevertheless, seldom adequately covered with spray. The view is put forward that spraying attains control for the most part by interfering with the production of Cercospora spores and by affecting the germination of spores which may reach the unsprayed heart leaf —a conclusion which may not receive general complete acceptance. Shade has again been found to be an important factor in reducing spore production in that it also reduces dew formation. An indication has also been obtained that appreciable damage from secondary infection on older leaves occurs only spasmodically, under conditions as yet undetermined although apparently connected with a marked fluctuation in soil moisture conditions. The general conclusion is reached that the nature of leaf spot disease is essentially cumulative.

Inheritance of Pits in the Ears

PITS in the ears which sometimes simulate holes pierced for ear-rings are shown to be inherited in man by H. W. Edwards and C. E. Keeler (*J. Hered.*, 31, 507–510; 1941). These pits on both lateral and medial surface of the lobe of the ear do not usually form a channel through the ear, but appear similar to old, healed, ear-ring puncture marks. The character is inherited in two families as an irregular dominant, with indications of other factors which modify the expression.

Topography of the Red Sea

A REPORT issued by the Egyptian Biological Station at Ghardaqa contains an account of its preliminary exploration of the Red Sea, arranged under C. Crossland in H.E.M.S. *Mabahith*, which was fitted with sonic sounding. The cruises included six traverses across the northern part of the Red Sea, a special investigation of the entrance to the Gulf of Aqaba and two sections along its length and five across. The Gulf of Suez is a shallow shelf at 30–40 fm., while Aqaba is separated by a sill at 140 fm. Within there is a depth of more than 1,000 fm.; this occurs on its east side where the slope is practically a precipice, ending in the cliffs of mountains equally high above sea-level. For charting, adjustments of the echo soundings have to be made, for the echo comes from the nearest land face, so that in front of a precipice it will be at a considerable angle to the vertical. In the Red Sea the long trough more than 1,000 fm. deep proved to be a narrow valley, a regular rift feature. The descent to this is by a series of steps, some of which on the Arabian side are reached by precipitous falls of 400–500 fm. Indeed the features described by Wharton for Masamarhu seem topographically to be quite general in the Red Sea off coasts and islands; there were also found many pinnacle reefs reaching sea-level. Sedimentation was found to be very small in all parts, so that the slopes were never masked.

Source of Copper in Ore Deposits

C. H. WHITE has recently discussed the concentration, distribution, and origin of copper ores in the earth's crust (*Economic Geol.*, 36, 1; 1941). Although copper occurs in traces throughout the earth's crust, commercial deposits of copper ores occur only where the crust has been fractured by faults, fissures or shear. The ores are found in rocks of all types, sedimentary, igneous and metamorphic, and their deposition has especially followed periods of profound crustal deformation. Careful study has shown that deposits long thought to be magmatic segregations—like those of Sudbury—are in reality metasomatic replacements, genuine magmatic segregations, if any, being small and unimportant. It is known from observation that sulphides ascending from the depths are capable of replacing practically every other mineral in their path if conditions are favourable. Igneous intrusions do not occur in all copper districts. Where they do occur the usual sequence is (*a*) acid magma; (*b*) basic magma; (*c*) mineralization by copper sulphides. It is suggested that as the earth cooled to temperatures permitting chemical union of the atoms, the interaction of physical and chemical forces, notably gravity and the combination of the elements in the order of the heats of formation of their compounds, led to the concentration of copper and sulphur and of other similarly less chemically active heavy metals and their associated anions, to a zone underlying the silicate crust, where they remained until released by sub-crustal fractures. If fractures reach only to the level where acid magma is generated, granitic magma ascends; if they tap the basic zone, basaltic magma ascends; and only if they reach through to the sulphide zone do ores ascend. A similar hypothesis, based quite independently on the difference between the atomic weight of ore-lead and that of rock-lead has been proposed for lead ores by Holmes (*Econ. Geol.*, 32, 782; 1932: 33, 829; 1938).

Coupling of Diazonium Salts

A kinetic study of the coupling of diazonium salts with phenols made by Conant and Peterson in 1930 indicated that the measured rate was governed by an acid-base equilibrium in one or other of the reactants:

$$(1)\quad ArN_2^+ + OH^- \rightleftharpoons ArN_2OH$$
$$(2)\quad ArOH \rightleftharpoons ArO^- + H^+.$$

The conclusion was reached that the reaction was between undissociated phenol and undissociated diazo-hydroxide, the effect of alkali being to promote the reaction by increasing the amount of diazo-hydroxide. R. Wistar and P. D. Bartlett (*J. Amer. Chem. Soc.*, 63, 413; 1941) have studied the coupling with aromatic amines, reaction (2) being replaced by

$$(3)\quad ArNH_2 + H^+ \rightleftharpoons ArNH_3^+.$$

In this case the acid-base equilibrium reaches 50 per cent in the region of acidity corresponding with maximum velocity. There are four possibilities for the reaction: (1) diazo-hydroxide couples with the ammonium ion, (ii) diazonium ion couples with free amine, (iii) diazonium ion couples with ammonium ion, (iv) diazo-hydroxide couples with free amine. A kinetic study of the influence of *p*H on the coupling of 1-naphthylamine-4-sulphonic acid and diazotized sulphanilic acid and of 1-naphthyl-amine-8-sulphonic acid and diazotized aniline was consistent with two mechanisms, but only one of these was in harmony with the facts regarding the activating and directive influence of aromatic substituents on the coupling reaction. It was thus shown that the active components in the coupling reaction are the diazonium cation and the free amine or phenoxide ion. C. R. Hauser and D. S. Breslow (*ibid.*, 418) also reach the conclusion that the diazonium ion is involved rather than the diazohydroxide, and show that this is in agreement with accepted electronic theories, the ion being an electron-accepting component and representable in two resonance forms.

Determination of Zinc in Magnesium Alloys and Zinc Alloys

E. Q. Laws discussed the above at a meeting of the Society of Public Analysts and other Analytical Chemists held on February 5. The precipitation of zinc as sulphide from a buffered solution of formic acid and ammonium formate, investigated by Fales and Ware, is shown to afford a rapid and accurate means of separating zinc from a large excess of magnesium, aluminium, nickel, manganese and iron. Details were given of the application of the method to the determination of zinc (*a*) in synthetic mixtures, (*b*) in magnesium alloys containing 5–10 per cent of aluminium, 0·7–3 per cent of zinc and 0·5–1 per cent of iron, and (*c*) to copper-nickel-zinc alloys containing 20 per cent of zinc, 45 per cent of nickel, 0·5 per cent of manganese, 1 per cent of iron and the rest copper. With (*b*) it was found necessary to redissolve and reprecipitate the zinc sulphide; with (*c*) the copper was first removed electrolytically and a single precipitation of the zinc sufficed.

Origin of Transient Ionic Clouds

In a theoretical note, P. M. S. Blackett and A. C. B. Lovell (*Proc. Roy. Soc.*, A, 177, 183; 1940) suggest that the origin of some of the transient ionic clouds, generally assumed to be responsible for the low-level sporadic radio reflexions, may be due to large cosmic ray showers. Cascade cosmic ray showers of sufficient energy to produce some of these radio reflexions have been recorded, but the data are inadequate for a test of the theory. More suitable results could be got from the frequency-size distribution of the radio echoes observed from a horizontal or vertically directed beam.

X-Ray Crystallography and Chemistry of the Steroids

A comprehensive survey of the X-ray crystallography of some eighty sterol derivatives belonging mainly to the cholesterol and ergosterol series but including also calciferol and other photo-derivatives of ergosterol and some higher plant and animal sterols has been made by J. D. Bernal, D. Crowfoot and I. Fankuchen (*Phil. Trans. Roy. Soc.*, A, 239, 135; 1940). The crystallographic measurements are discussed in their bearing on specific chemical problems of characterization and identification, determination of molecular weight, the stereochemistry of the carbon skeleton, the effect of substituents on the crystallography of the sterols, a comparison of the crystallography of different sterols—monohydroxy compounds and the structure of calciferol. The survey illustrated very plainly the limitations of preliminary crystallographic study as a source of chemical information. Even in matters of straight identification, there may be difficulties where impure preparations consisting largely of mixed crystals or where polymorphic modifications are concerned. Exact X-ray analysis of carefully selected substances is proposed.

Stellar Colour Temperatures

It is now recognized that the continuous radiation of the stars cannot be represented even approximately by Planck curves over all observable wavelengths. The recent discovery that negative ions of hydrogen may make an important contribution to the opacity of stellar atmospheres leads R. Wildt (*Astrophys. J.*, 93, 47; 1941) to inquire whether the observed energy distribution curves can be reproduced from theoretical considerations, knowing the absorption coefficients of H and H^-, and assuming the absorbing atmosphere to consist of these particles only. He finds that this can be done tolerably well for early-type (*A*0 to *F*0) stars. For later spectral types, however, the predicted colour temperatures fall below the effective temperatures, whereas the observed values are much higher. Moreover, no addition of absorbing metallic atoms to the hypothetical atmosphere can improve matters, since metallic absorption in a late-type star rises steeply towards the violet, and therefore lowers the colour temperature still further. Thus it seems that yet another attempt to reconcile theoretical colour temperatures with observed values has failed. At present it looks as if further attempts will also fail unless they embody some hitherto unknown mechanism which produces an absorption coefficient decreasing from the near infra-red towards the violet.

Systematic Corrections to Proper Motions

W. M. Smart has discussed (*Mon. Not. Roy. Astro. Soc.*, 101, 1) the "Systematic Corrections to the Proper Motions of the General Catalogue" more fully and accurately than previous investigators have done. It is pointed out that in the discussion undertaken by R. E. Wilson and H. Raymond (*Astrophys. J.*, 47, 49; 1938) the elements of the solar motion, the precessional corrections and the constants of galatic rotation were derived from two solutions, one based on Schönfeld's equations in equatorial co-ordinates, and the second in galactic co-ordinates. As Miss Emma Williams has shown, however, the equatorial equations are incomplete so far as the rotational effect is concerned, because the double-wave term which depends upon Oort's constant, *A*, is omitted. In addition, some small adjustments were necessary owing to a misinterpretation of Schönfeld's notation and the omission of a factor. Smart points out also that the numerical formulæ which Wilson and Raymond have derived (*Astrophys., J.*, 47, 57; 1937) for the systematic corrections to the proper-motion components are incomplete and do not fully satisfy the requirements of investigations dealing with small proper motions. In the present paper Smart applies the best available systematic corrections and derives the equations of condition for the elements mentioned above in literal form. Tables I and II supply the values of the corrections $\Delta\mu_\alpha \cos \delta$ and $\Delta\mu_\delta$, the unit being 0·01″ per century. Literal equations are also given when the solution is effected in galactic co-ordinates.

DEVELOPMENT OF THE FRONTAL BONES OF THE RAINBOW TROUT

By J. A. Moy-Thomas,

Department of Zoology and Comparative Anatomy, Oxford

THE causes responsible for the development of the dermal bones of the skull in fishes have been the basis of much speculation by morphologists and palæontologists. Although this problem has been a popular one with workers in recent years, almost all the theories which have been formulated have been deduced either from purely morphological evidence or from abnormalities found in Nature, and so far as I am aware, the only experimental work of importance is that of Tatarko[1] on the opercular apparatus of the carp. His experiments, however, deal exclusively with the regeneration of bones and not with their development.

The experiments which are described below were undertaken by me with the object of throwing light on some of the more outstanding problems connected with the formation of the frontal bones in the trout. The method employed was a modification of that described by Hoadley[2] for Fundulus, in which pieces of embryos were removed through the egg-membrane by pricking with a glass needle and squeezing out the desired part by means of a small glass ring on a glass rod. Trout proved particularly satisfactory material for this work as they are very easy to keep alive, and do not require feeding until the yolk sac is absorbed, at which stage they are nearly fully developed. If necessary, however, they will readily feed and flourish on a little pounded liver. The trout used in the experiments were rainbow trout supplied by the Midland Fisheries, Nailsworth, Gloucester.

On theoretical grounds it has been suggested that the sense organs of the lateral line canal system of the head are important agents in stimulating bone formation in their vicinity. This view is based very largely on observations by Pehrson[3] on the development of the skull of Amia. Pehrson showed that those dermal bones which in the adult are connected with the lateral line canals start their development as aggregations of osteoblasts around certain of the sense organs of this system. The osteoblasts then give rise to small rudiments of bone around the sense organs, which may or may not in later development fuse with adjacent rudiments to form the adult bones. From this early association of the lateral line sense organs and certain dermal bones it has been argued that the former are the cause of the development of the latter. Many writers have attributed so much importance to this assumption that they have based their ideas of bone 'homology' to a great extent on it.

The experiments which I have carried out show that no such causal relationship exists. The rudiments of the lateral line canal system were removed from one side of the roof of the skull of an early trout embryo, shortly after the formation of the eyes. At this early stage no traces of sense organs or frontal can be distinguished in this region. The result of such an operation was to produce a fish in which the frontals were developed on both the right and left sides, but the frontal on the operated side, where there were no sense organs in its immediate neighbourhood, was rather less advanced in its development than that of the other side.

Similarly in fishes in which two or three sense organs and a piece of the canal are removed from the middle of the frontal region, the frontal develops normally, but the bony 'gutter' usually formed round the canal is absent in the region where the organs have been extirpated.

These two sets of experiments demonstrate conclusively that the actual origin of the frontals during development is due to some cause other than the presence of the sense organs of the lateral line canal. The lateral line itself appears only to be capable of stimulating bone formation in its own close vicinity, but not of initiating the appearance of a frontal.

Two further sets of experiments were carried out to demonstrate the influence of the brain on the development of the frontals. In one lot the greater part of the brain, namely, the forebrain, optic lobes and most of the cerebellum, was extirpated at an early stage, when the neurocranial part of the chondrocranium consisted only of trabeculæ, parachordals and the rudiments of the cartilaginous auditory capsules. The skull resulting from this brain removal consisted of fairly normal olfactory and auditory regions, but the intervening taenia marginales were fused into a continuous median rod leaving no cerebral cavity anteriorly to the auditory capsules. Nevertheless the frontals developed as paired bones. Their position relative to the taenia marginales and other cartilages in the neighbourhood, in which the frontals usually develop, was as nearly normal as possible. They were also connected with their appropriate lateral line canals, except of course in those cases where the latter had been removed. The operation of removing the brain obviously greatly reduces the quantity of tissue between the eyes, and the lateral line canals and the rudiments of the frontals lie relatively much closer together on top of the head. Thus the frontals have a very much smaller area to cover than normally, and it can be seen that the ossification around the sense-organs and canals is thicker and more advanced than in an unoperated animal of similar age.

These experiments demonstrate that the paired nature and origin of the frontals is not related in any way to the underlying brain. It is interesting to compare this artificially produced condition with that in microcephalic and anencephalic skulls in man. In these monstrosities the full complement of dermal bones is formed, but the brain-case is greatly reduced in size.

The second set of experiments consisted in removing the eye on one side of the embryo a short time after its appearance. As development proceeded the optic lobe of the unoperated side remained small, whereas that of the operated side, which innervated the remaining eye, increased in size at the normal rate of development. The greater part of the frontals usually cover the optic lobes, and the bones of each side meet each other between the right and left optic lobes almost precisely in the middle line. However, in the operated individuals in which the optic lobes are unequal this relation between frontals and the brain no longer exists, each frontal growing towards the middle line of the head at more or less its normal rate. The frontal of the unoperated side thus comes to extend beyond the middle line of the brain over the optic lobe of the other side. From these experiments, therefore, it can be concluded that the median suture of the frontals is independent of the underlying brain. Although these results are such as would on general grounds be expected, they are opposed to the interpretation put by Troitsky[4] on his experiments with the dog's skull.

Although the experiments here described throw no positive light on the nature of the processes governing the initiation of ossification at certain definite places in a developing skull, they do much to dispose of some commonly held but erroneous views, especially those concerned with the lateral line canal. The repercussion of these conclusions on the method of homologizing dermal bones appears to me to be very important to morphologists generally, and will be discussed at length when this work is published in full.

PSYCHOLOGICAL ASPECTS OF COLOUR MEASUREMENT

By Dr. H. J. Eysenck
University College, London

COLOUR STANDARDIZATION has two aspects which are of equal importance—the physicochemical and the psychological. The work of Ostwald[1] has been severely criticized in NATURE by J. Guild with regard to its physico-chemical foundations[2]; with Ostwald's psychological and æsthetic considerations Guild refuses to deal, because "they have no relevance to colour measurement" (p. 272). To the psychologist, however, it is just these considerations which are of the greatest interest, particularly as the great success which the Ostwald system has had commercially both in Great Britain and in Germany indicates that the needs which Ostwald attempted to meet are very real needs among those who have to deal professionally with colours, coloured papers and the like. An examination of the claims advanced on behalf of Ostwald's "Colour-Science" in the psychological sphere may therefore not be out of place, especially at the present moment, when a *psychological* standardization, such as Ostwald attempted, may easily be of great importance in the practice of camouflage, where, as in pictorial art, human perception and not physical apparatus is the ultimate arbiter of colour and brightness equalities and differences.

The two main claims made by Ostwald with regard to his system are (*a*) that his eight standard greys, the differences between which are based on the Weber–Fechner law, are equidistant psychologically, and (*b*) that the twenty-four colours which go to make up his colour-circle are also psychologically equidistant. Several further claims are made with regard to the æsthetic qualities of certain relations obtaining between both the greys and the colours, the two main of which are (*c*) that triads made up of three greys the differences between which are equal according to his system are especially pleasing, and (*d*) that diads made up of two colours which are eight steps apart on his colour-circle are also especially pleasing.

These four claims were submitted to experimental tests, and the results are reported below. The materials used were the coloured papers produced by the W. Ostwald Farben G.M.B.H., and wherever possible the results were checked up with the dyed fabrics given in his book. (The papers are produced very carefully according to Ostwald's own formulæ, and give, as he himself acknowledges, a very good approximation to the colours intended. It would, of course, be preferable in some ways to work with coloured lights, but Ostwald is very emphatic in his assertion that his laws apply only to *reflected* light.)

(*a*) Ostwald's first claim was tested in two ways. (1) Twelve subjects were given seven cards on each of which two consecutive Ostwald greys were affixed, and asked to judge the amount of 'difference' of the two greys on each card as compared to the others by the method of paired comparison. The following results were reached:

Greys	Judged 'Larger than'	Judged 'Smaller than'	Judged 'Equal to'
a/c	93 per cent	0 per cent	7 per cent
c/e	38	13	49
e/g	37	18	45
g/i	33	17	50
i/l	33	18	49
l/n	3	85	12
n/p	0	86	14

The second test was carried out by means of a method suggested by Barnhart[3], and particularly well adapted to questions of this kind. (2) Ten subjects were asked to arrange rectangular pieces of paper, each cut from one of the eight greys, on specially prepared sectional paper in such a way that the distance on the paper was to be taken as an indication of the difference in brightness between them. The average distance for all the greys being put at 1·00, the average distances between any two consecutive greys were: $a/c = 1\cdot 8$; $c/e = 1\cdot 2$; $e/g = 1\cdot 0$; $g/i = 0\cdot 9$; $i/l = 1\cdot 0$; $l/n = 0\cdot 6$; $n/p = 0\cdot 5$. Thus the two methods give much the same results: while the greys in the middle are more or less equidistant, grey *a* is too far away from grey *c*, and the last three greys (*l*, *n*, and *p*) are much too close together. This result is not unexpected in view of the results reported by König[4], Burkamp[5] and others, with regard to the limited applicability of the Weber–Fechner law to brightness differences.

(*b*) A similar method was adopted in testing Ostwald's claim with regard to the colour-circle. Two concentric circles, of diameters 50 and 52 inches respectively, were drawn on white cardboard, and the ring between them divided into 48 equal parts. From the 24 Ostwald colours pieces were then cut out in the exact shape of the ring-segments, and laid on the ring in such a way that each piece was followed by a blank segment. Twelve subjects were told that the average difference between one colour and the next was represented by one blank space on the chart, and that if anywhere they noted that two colours were either too close together, or too far apart to be fairly represented by a distance of one space, they should change the distance until it represented as accurately as possible their opinion of the difference. The following table gives the average amount of change advocated, indicating both direction and size of the change. A + sign indicates that on Ostwald's circle the distance between the two colours is too small, and should be increased by the amount shown; a − sign indicates that the distance should be diminished by the amount shown.

Colours	Change	Colours	Change
1 and 2	−0·83	14 and 15	−0·50
5 and 6	−0·58	16 and 17	−1·00
7 and 8	+0·75	18 and 19	−0·92
12 and 13	+1·17	20 and 21	−0·25
13 and 14	+0·17	24 and 1	+1·58

It is clear that in view of these results the validity of Ostwald's claim must be seriously doubted.

(*c*) For testing Ostwald's third claim, eight grey *harmonies* were constructed in accordance with his specifications, and eight grey *combinations*, made up to contravene his principles. The size of the inequality in these combinations varied from 1 to 3 steps. The 16 triads were ranked in order of liking by six subjects, the average intercorrelation between them being 0·49. The average order of these subjects would correlate with the true order of the whole population of which they were only a sample to the extent of approximately 0·92 (footnote 6, and references); hence we may take their average ranking as a fairly close approximation to the 'true order'. On the average, the *harmonies* are ranked 8·7, the *combinations* 8·3; in other words, if anything the *combinations* are preferred. The best-liked triad is a combination, the least-liked a harmony. This adverse result seems due, however, not so much to any fault in Ostwald's proposed law, as rather to the inaccuracy of the spacing of the greys in his system; introspective evidence shows that the combinations and harmonies most preferred are those in which the differences are seen as equal.

(*d*) To test Ostwald's last claim, 48 diads were used. There are 24 diads which have a circle distance of 8 steps; in addition 12 diads were included with a circle distance of 5 steps and another 12 with a circle distance of 11 steps. Ten subjects arranged these forty-eight diads in order of liking, giving the following average number of points to each group (a scheme of grouping, closely following the normal distribution curve, was adopted in the ranking, as with 48 items the assumption of linearity implicit in the straightforward ranking procedure is likely to be false):

Circle-distance, 5 steps: 3·8 points.
Circle distance, 8 steps: 4·5 points.
Circle distance, 11 steps: 5·2 points.

Thus on the average the greater the circle distance, the better liked were the diads. This finding bears out Kirschmann's First Law, namely, that "combinations are pleasant if they yield a maximum . . . contrast effect"[7]. Additional experiments, involving the ranking of the 24 constituent colours of the diads by the same subjects, also confirm his tenth law, namely, that "the pleasantness or unpleasantness of the single colours affects the pleasantness or unpleasantness of their combinations". The influence of these two factors seems to be about equal, each contributing some 25 per cent to the final ranking.

Thus here also, as in the previous experiments, empirical investigation fails to support Ostwald's claims. In spite of this disappointing conclusion, I believe that the main aims which Ostwald hoped to reach are eminently worth while, and that a repetition of his work with the proper statistical and experimental safeguards would lead to great progress in those applied arts and sciences which to some degree depend on colour, such as art teaching, poster designing and camouflage.

CONDENSING PLANT FOR POWER STATIONS

THE design of steam condensing plant and associated cooling water systems for power stations was considered from the economic point of view in a paper by W. T. Bottomley (Messrs. Merz and McLellan, consultants) submitted to the North East Coast Institution of Engineers and Shipbuilders at Newcastle-upon-Tyne on March 28.

Mr. Bottomley showed that the condensing plant should be designed to fit the circulating-water system, the ratio of the quantity circulating to the tube surface area depending on the length of the water system. Thus for a station close to the bank of a non-tidal river, the ratio should be considerably larger than when tidal water can be utilized. Data are included indicating the performance of the condensers at the Dunston "B" station of the North-Eastern Electric Supply Co., together with the results of cooling tower tests carried out at the Darlington municipal generating station.

Mr. Bottomley's deductions are that the economical water velocity through the tubes, the size of condenser, quantity of water circulating and size of cooling tower can each be determined independently of the others and depend on cost ratios, as does also the economical ratio of water to the surface in the condenser.

Under dirty conditions, the economical load on a condenser should be about 5,300 B.Th.U. per sq. ft. for base-load stations, instead of the generally recommended figure of 7,000. When the size of the turbine house building is fixed, it pays to install the largest condenser possible in the space available.

The relation between the normal vacuum in the condenser and the average temperature of the inlet circulating water has been practically fixed by convention. The sizes of condensers built in the United States are much the same as those built in Great Britain, but the quantity of water used is sometimes greater. Port Washington Power Station (U.S.A.) is the most efficient power station in the world. Monthly and yearly average operating figures are published from time to time. In 1937 the average load for the machines was nearly steady at 53,000 kilowatts. The greatest monthly average temperature rise of water, 4·2° F. above that of the circulating water inlet, occurred in March, and the smallest rise, 4·0° F., occurred in August. The temperature rise of the circulating water of about 4·0° F. shows that the quantity of the circulating water is nearly 250 times the quantity of the steam condensed. It has to be noted that whatever the conventions adopted twenty years ago, prices and conditions have now considerably altered. The most important of these is the average loading of the plant, which, especially in base-load power stations, is considerably higher now than ever before. The cost of fuel per kilowatt-hour has not materially altered. The fuel consumption per unit has been reduced to a half during the last thirty years. This has been offset to a large extent by the rise in the price of coal, which is now double what it was. When river water is used for cooling, the temperature of the water is the theoretical lower temperature of the cycle; for cooling tower schemes it is the atmospheric wet bulb temperature. In a given locality, these two temperatures on the average are about the same: for example, about 52° F. in Great Britain.

The approach of the condensing temperature to the theoretical temperature is limited by the question of cost, and the aim of the engineer is to design the plant so that the total annual cost including capital charges is a minimum. Mr. Bottomley shows mathematically that for conditions of minimum cost, the size of the condenser, the size of the tower and the quantity of circulating water can each be determined independently of the others, and this considerably simplifies the problem.

Among the important conclusions deduced is that the effect of deposit on the tubes can only be counteracted by increasing the tube surface and reducing the water velocity. No advantage is gained by increasing the quantity of the circulating water. Bearing in mind the cost of the circulating-water system and the cost of pumping, it is clear that the longer the circulating-water system is, the more the quantity of the circulating water should be reduced and the lower should be the normal vacuum in the condenser. Subject to the ground being suitable to bear the weight, power stations using tidal-river water cooling should be placed as near as possible to the river front, as this reduces the length and cost of the circulating-water system and also improves the overall efficiency of the station. By placing the station on the river front, a saving of about one per cent in the fuel consumption can be effected without reducing the distance between the intake and the discharge to the river, compared with a station placed about 800 ft. from the bank.

PLANNING IN GREAT BRITAIN

A CONFERENCE on National Planning arranged by the Garden Cities and Town Planning Association was held at Oxford on March 28–30. An abstract of the valuable survey presented by Dr. Dudley Stamp at the Conference has already appeared in NATURE of May 24, p. 647. In what follows, digests are presented of some of the other contributions.

Mr. D. E. Gibson's paper on problems of decentralization, central development and satellite towns, while outlining the plans adopted by the Coventry City Council as a basis for Lord Reith's investigation, was essentially a discussion of some of these fundamental problems. It is obvious that we must have an idea of the size of the city for which we are planning before any intelligent planning is possible, and this is true whether of amenity services or of such problems as transport and roads. Such a question can only be answered when national planning arrangements have been made. National planning by the Government, as Mr. Gibson points out, is vital, because such information is required by all planning authorities in the country.

The valuable reports of the Barlow Commission and of P E P (Political and Economic Planning) do not supply all the material that is required as a basis for legislation, though the Conference re-directed attention to them, and Mr. H. W. J. Hick in particular, in his paper on "The Machinery of Planning", urged the adoption of the findings of the Barlow Commission with the reservations and amendments of the signatories of the Minority Report. The field for further investigations, however, is admirably illustrated in some notes for discussion on planning principles by Mr. W. Harding Thompson, which formed one of the most valuable contributions to the Conference.

Mr. Thompson shows that while there may be general agreement as to the objectives of planning, and the argument for decentralization may be regarded as accepted as a basis of policy for the central planning authority, changes occurring during the War must be taken into consideration. Some war factories may form the nuclei for new industrial settlements, but the central authority must at least provide a general outline plan on very broad lines for national zoning of industry. This plan, moreover, must take account of the balance of community life as well as of other economic and æsthetic factors. Planned redistribution is probably best applied to the numerous light and mobile industries with their wide choice of location.

The unit of regional planning also requires consideration in the light of experience of the civil defence regions. Mr. Thompson throws out as one suggestion the formation of industrial and agricultural planning boards, and stresses the necessity of harmonizing conflicting requirements of various

Government Departments by the central or regional authority before transmission to local authorities, if local planning schemes are not to be delayed and confused. He reiterates with Mr. Gibson the importance of a local planning authority or joint committee deciding on the optimum size and population of a town before planning for increased industrial activity. Expansion beyond that size should be by means of adjacent satellite or independent new communities within the region, each surrounded by a green belt.

The question of the optimum size of towns is one of the major problems on which further research is required. Obviously it may vary in accordance with physical limitations, the character and function of the town, the labour conditions, possible services, strategic situation and population required to support cultural activities, etc., and the analysis in the P E P report requires extension to some practical conclusion. The maximum density of development for urban areas, especially in residential units, is another matter in which further guidance is required, while the relation of agricultural to other industries established in rural districts needs investigation in several respects. The possibility of a further decrease of agricultural workers in Britain after the War, due to scientific and mechanized methods of farming and as a part of Imperial agricultural policy, must be seriously considered both in its effect on the vitality and mortality statistics and in relation to food policy and possible changes in production such as extended market gardening. Equally we have to consider the possibility of stabilizing and revitalizing rural community life by the introduction of selected light industries in villages, and the ways and means of safeguarding the benefits in health which have already flowed from the closer contact through evacuation of town workers with rural life.

Prof. J. H. Jones advocated the immediate establishment of regional boards, under the chairmanship of the Civil Defence Commissioners, to control the location of industry, and urged that the Government should decide whether the present Ministry of Works and Buildings is to be the effective Ministry of Reconstruction or to be superseded. Dr. Robson, in stressing the advantages of immediate planning to the war effort, holds that industry is capable of more control in its location than Prof. Jones suggested.

There can be no doubt that there are wide fields in which the planning of post-war Britain and the research and technique involved in reconstruction could be undertaken now with direct advantage to our war effort, apart altogether from the effect on public morale. There is much educational work to be undertaken, not merely of the general public, but also post-graduate education in such fields as organic planning, quantitative study of zoning areas, factory-building, shopbuilding, leasing and rent-fixing, control of use and design—aspects and techniques of town-building which, as Mr. F. J. Osborn pointed out, are not adequately covered in present town-planning education. There is also the vital contribution of the Building Research Station in regard to the use of new materials of construction as well as in matters of design, and here again research must be linked up with the development of new techniques and much far-reaching educational work.

CRUSTAL STRUCTURE OF NEW ZEALAND

K. E. BULLEN states that the progress of instrumental seismology has been slower in New Zealand than in a number of other earthquake regions, and it was not until the present decade that the identification of phases other than the normal P and S could be made in the records of near earthquakes (K. E. Bullen, "The Crustal Structure of the New Zealand Region as inferred from Studies of Earthquake Waves", Proc. Sixth Pacific Science Congress, 1939). The subsequent studies of the crustal structure of the New Zealand region have been subject to a number of special difficulties, of which some, but not all, have since been resolved or modified.

These difficulties centre chiefly around the considerable uncertainties in the determination of epicentres and origin times of many of the earthquakes which have shown phases in addition to P_n and S_n. Epicentres are in general best determined from the absolute arrival times of P_n at a sufficient number of stations, but until recently Wellington and Christchurch were the only stations the absolute time of which could be relied upon for such a purpose. This has necessitated recourse to $P_n - S_n$ intervals with the attendant difficulties of the accurate identification of the onset of S_n. There were doubts also concerning the normal P velocity immediately below the crustal layers, and therefore by implication in the corresponding S velocity also. A step forward was taken by Bullen when the significance of the phase S^* was recognized in New Zealand earthquakes, following a study of the aftershocks of the Hawke's Bay earthquakes of February 2, 1931. It would appear that S^* has been recorded more often than any other phase in New Zealand and that S^* may sometimes be recorded when the normal S_n is completely missed. A revision of the analysis of the Wairoa earthquake of September 15, 1932, and of the Pahiatua earthquake of 1934 has led to further improvement. Statistical methods have been used wherever possible.

The new epicentre of the Wairoa earthquake was considered so satisfactory that new travel-time curves were prepared which, Bullen believes, approximate to the best results obtainable for the New Zealand region on the data so far available. The data refer particularly to that part of New Zealand which lies between latitudes 38·5° S. and 43·5° S. From these data P^n up to 4° has a velocity of 8·1 km./sec. though the normal 7·8 km./sec. fits nearer 6°. There are signs that P^* is double with velocities 6·55 and 6·0 km./sec. $P_{6\cdot0}$ and $S_{3\cdot0}$ have additionally been recognized, the former making S_n difficult to recognize at some stations. $P_{5\cdot0}$ has also been recognized by geophysical prospectors in New Zealand and may correspond to travel paths through greywacke, which occurs abundantly in the region between Wairoa and Wellington.

In conclusion, it is suggested by Bullen that the structure may be: (1) uppermost layer, perhaps a greywacke for a good part of the region, thickness 5–10 km. with velocity of P 5·0 km./sec. and S 3·0 km./sec.; (2) granitic layer, 4 km. thick with velocity of P 5·5 km./sec.; (3) intermediate layers, 10–20 km. thick altogether with velocities of P 6·0, 6·3, 6·5 and 7·0 km./sec. and in the lower part S 3·7 km./sec.; (4) lower layer dunite with base uncertain, velocity of P 7·8 (?) km./sec. and S 4·4 km./sec. This varies somewhat from the European structure, chiefly in having a thinner granitic layer and a thicker intermediate layer than Europe. The phase $P_{6\cdot 0}$ may correspond to the phase P_Y in California, and it is suggested that there may be some resemblance between the crustal structures of New Zealand and Japan.

PLANTS USEFUL AND ORNAMENTAL

UNLESS he be a professed systematist, the modern botanist, newly arrived in the tropics, as also the horticulturist and agriculturist, may well find himself bewildered and dismayed, as well as bewitched, by the diversity and profusion of the vegetable forms which everywhere greet the eye. Those first encounters, indeed, provide a pleasure not entirely devoid of pain; they force a realization of the small knowledge that one so often brings to a vast subject. Such local works as afford simple and direct guidance in the identification of the more common genera and species are therefore of great value and should be appreciated accordingly.

In this category is the volume just issued by R. O. Williams and R. O. Williams, jun. ("The Useful and Ornamental Plants of Trinidad and Tobago", third edition, Government Printers, Trinidad), the original edition having been published by W. G. Freeman and R. O. Williams in 1927 and a second in 1928. The object, in the first instance, was to give information about native and introduced plants possessing interest because of their useful and ornamental qualities. Actually, a brief random sampling shows that the title errs on the side of modesty, for many plants, not essentially useful or ornamental, but of considerable botanical interest, are also described—a feature not only desirable in itself but also one which lends a fullness to the work.

The Colony, as the authors state, possesses many wild plants, prized for their economic or decorative value; and many plants have been successfully introduced from all parts of the world. "To obtain information on many of these is often difficult, even in a well appointed botanical library, entailing search through various standard works of reference, and often the agricultural, botanical and other publications of several other countries. To the person not so equipped the task is frequently a hopeless one." Thus appreciating the need, the authors have successfully fulfilled their task. In this edition the lists of useful plants have been completely rearranged and keys have been provided to facilitate identifications. Cultural notes make a useful addition to plant descriptions and notes on crop plants have been brought up to date.

It is a pleasant occupation to make an excursion at random through such a work, where East meets West and where the denizen of the high woods comes to rest by the side of more everyday garden staples, but for the botanist the features of greatest interest are perhaps those sections where orchids, ferns, grasses, cycads, conifers, cacti and mangroves are treated as groups. At a glance the wealth of the Islands can be seen. Further, what is true of the major groups is true of the flora as a whole; the number of native and introduced plants possessing particular interest is surprising.

FORTHCOMING EVENTS

Thursday, June 5

ROYAL SOCIETY OF MEDICINE (at 1 Wimpole Street, London, W.1) at 5.30 p.m.—Prof. Julian Huxley, F.R.S.: "Art as a Social Function" (Lloyd Roberts Lecture).

CHEMICAL SOCIETY, INSTITUTE OF CHEMISTRY, and SOCIETY OF CHEMICAL INDUSTRY (Joint Meeting in the University Chemical Department, Bristol) at 6.30 p.m.—Prof. G. M. Bennett: "Liquid Crystals".

APPOINTMENTS VACANT

LECTURER IN MECHANICAL ENGINEERING—The Principal, Aston Technical College, Whitehead Road, Birmingham 6 (June 7).

LECTURER IN PHARMACY and LECTURERS IN MECHANICAL ENGINEERING—The Principal, Central Technical College, Suffolk Street, Birmingham 1 (June 7).

SENIOR LECTURER IN THE DEPARTMENT OF ELECTRICAL ENGINEERING—The Principal, Heriot-Watt College, Edinburgh (June 9).

ECONOMIC POLICY TO-DAY AND TO-MORROW

RECENT debates in the House of Commons, notably on the War Damage Bill, have amply vindicated the value of our democratic institutions in sustaining and guiding the national effort. Without questioning its confidence in the present Government, the House of Commons shows no signs of abdicating its associated practice of vigilant supervision and the voicing of public opinion ; and by its co-operation with the Government as a kind of Council of State, while maintaining its vigilant watch over policy and achievement, its sensitive interpretation of public opinion and constructive but searching criticism of administration has gone far to rehabilitate the prestige of Parliament and silence criticism which was rampant in the years immediately before the War. Mr. Pethick-Lawrence claimed with justice that in the War Damage Act debates we see democracy at its best, and Sir Percy Harris added that "the Chancellor has justified, in war-time, the working of the democratic machine. The House of Commons has been for this Bill, a Council of State." Much the same could have been said of the recent debate on the War, when keen criticism was focused on those questions of production and man-power which have so far restricted severely our policy and our strategy.

Nor is the House of Commons alone in exercising such functions. It is reinforced by its own Select Committee on National Expenditure, the reports of which, inspired by a wide view of its functions, have been models of the type of searching scrutiny and constructive proposals demanded, and have admirably supplemented the work of the House of Commons. Other bodies also are maintaining a watchful attitude. Among them is the Vigilance-for-Victory Group, composed primarily of politicians, prominent newspaper men and publicists who can report accurately upon public opinion and give it expression, and experts of trade and the professions affected by the problems which the Group examines. Its bulletins are complementary to the admirable contributions which the broadsheets issued by Political and Economic Planning (P E P) have already made to the national effort, and they supply an example of the type of contribution which scientific workers themselves may be expected to make in their own particular fields.

Informed, searching and constructive criticism is one of the first duties of the scientific worker ; there should be no excuse for slackness in this field either through failure to use effectively the machinery already established, from the Scientific Advisory Committee downwards, or to create new machinery if that already in existence is inadequate. They have, as it were, to play the same part as the Observer Corps to the Fighter Command, watching each situation as it develops in fields that are their special concern, and as quickly mobilizing expert opinion to consider and recommend effective and urgent measures to the authorities.

This is the view of its own functions taken by the Vigilance-for-Victory Group and is reflected in its fourth bulletin, which deals with the new plans of the Minister of Labour and National Service. The bulletin agrees with Mr. Bevin that compulsion should be avoided wherever possible on account of its effect on morale, but considers that more could have been done to reduce the need for compulsion by the comprehensive organization of all productive resources, especially of the distributive trades, which are probably the largest untapped source of man-power ; by a rational wages policy designed to facilitate the transfer of workers from non-essential to essential work ; and by a training scheme more attractive and extensive than that now in force. The measures now announced, it is considered, will not yield an adequate turnover of labour unless accompanied by an undesirable amount of compulsion. To be effective they must be supplemented by economic and financial planning of the kind which the Government has been reluctant to undertake.

Recent changes in the Government may indicate a belated move in this direction. The new appointment of Lord Beaverbrook as a Minister of State free from departmental duties may betoken recognition of the value of Cabinet Ministers capable of detached views and of co-ordinating policy, while the merging of the Ministries of Transport and Shipping is obviously intended to facilitate co-ordination. They are, however, only a short step towards the measures which the Vigilance-for-Victory Group believes are necessary.

In the sphere of industrial reorganization, the first need is to establish a pooled and controlled industrial machine, so as to increase productivity and facilitate the transfer of labour. The machinery for distributing orders for military and other supplies must then be reformed on a unified basis, and in the distribution of orders between localities the question of adequate labour supply must be one of the most important considerations. This latter point is also strongly made by Mr. G. D. H. Cole in an article on man-power in the *Political Quarterly* of April–June; Mr. Cole suggests that the regional shortage of workers is likely to be the principal difficulty in the way of expanding the output of munitions during the next twelve months.

This question is linked up with man-power policy, where the evolution of a national wage policy is the first essential. This depends on a rational consumption and price policy, that is, rationing, and on the establishment of a central wages tribunal. Revision of the wage structure is the next essential, including overtime for night shifts, so that it stimulates the transfer of labour where it is required. As a revision of relative wages must take place by an upward revision of the wages paid for occupations where man-power is needed, this depends, if inflation is to be avoided, on a strict rationing of goods. To improve the unsatisfactory position of training, the Vigilance-for-Victory bulletin, like Mr. Cole, recommends that training be paid as a job. Moreover, to prevent injustice or profiteering, billeting should be compulsory on the householder and all extra costs resulting from the transfer of labour borne by the State; stress is also laid upon finding a logical plan of compensation in place of the present system of allowances for members of the Fighting Forces.

Regional committees of production experts, with power to enforce their advice as to training, direction and use of skilled workers should be established, without interference from the Supply Departments, and appropriate social services should be introduced where necessary to increase the supply of man-power. These measures would go far to achieve the necessary transfer of labour by voluntary action. Certain measures enabling the Government to use compulsion, however, should also be enacted. The prohibition against leaving employment without permission should be replaced by a general prohibition of hiring without permission, and people not at the moment employed in industry should be required, by registration, to show reason why they are not in employment. If they do not fall into certain well-defined exempted categories, they should be asked to undertake suitable work. Modification of the unemployment insurance and assistance schemes for the duration of the War, securing to all displaced labour its previous wage and subsistence and separation allowances, provided it accepts training or suitable jobs, accompanied by a stringent and fair distribution of available supplies and goods by compulsory mobilization of property, and a fair system of taxation, would limit direct compulsion primarily to compelling *entrepreneurs* to reorganize production on a war-time basis. Reorganization on the supply side would minimize the necessity for migration, which is now causing most of the friction, discontent and bottlenecks.

These conclusions and recommendations are strikingly in harmony with the main points made by Mr. Cole, who considers that the problems arising out of migration—billeting, difficulties of transport and allowances and irrational differences in wages and earnings between one district and another—are the most serious obstacle to the full utilization of the available man-power of Great Britain. The second principal obstacle is the continuance, despite Government control, of each privately owned business as a separate unit, with which the Government departments enter into separate contracts. He considers that man-power could be much more effectively applied if the Government took over completely all the important munition-making firms, and pooled their resources in each locality under unified local management—in any event to the extent of grouping all firms engaged in closely related types of work. This step, by assisting transference, would help immensely to solve the other problems of labour migration.

Industrial mobilization is now proceeding on definite lines whether or not the pace can yet be regarded as satisfactory. The notion of a total war economy using all available reserves, specialized or otherwise, is gaining ground and the principle of complete concentration of those industries which are being contracted because they do not contribute directly to the war effort or to the maintenance of civil life has been unhesitatingly accepted. If, however, it is to be worked out adequately, it may be necessary for the Board of Trade to accept greater responsibility for directing industry towards the agreed ends. Certainly it cannot be achieved unless the policy of concentration and distribution of man-power is guided by a scientific and carefully worked-out plan.

Mr. Lyttelton in recent speeches has indeed shown an encouraging grasp of the essentials of war economics, and his statement of the Government's economic objectives in the War shows that it has already begun to think about post-war economic policy. These objectives he put under five heads: the mobilization of plant, raw materials, shipping, etc., for war production; secondly, the rationing of the civil population so that only essentials are made; thirdly, the mobilization of man-power; fourthly, the avoidance of inflation and the cheap finance of the war; and fifthly, the starting of the creation of post-war plans. Mr. Lyttelton already has a special section charged with examining particularly the problems of the first two or three years after the War.

Once again, then, we find that the war effort is linked up with post-war plans, and on this aspect Mr. Lyttelton makes two points. Internationally, we shall be a debtor nation and may require to continue a selective export policy and to control imports. We shall also have to prevent an unregulated replacement boom. Government control of industry can therefore only slowly be released, and must continue for some time after the War. The economic peace must rest on domestic and international regulation and co-operation. These points were elaborated in the speech made by Mr. Anthony Eden, on May 29, when he pointed out, among other matters, that the British Empire and Allies with the United States and South America will alone be able to undertake the reconstruction of Europe, and that "it will be our wish to work with others to prevent the starvation of the post-armistice period, the currency disorders and the wide fluctuations of employment, markets and prices" which followed the War of 1914–18.

Whatever may be thought of the adequacy of particular solutions, we are moving far from the assumptions on which our pre-war discussions of trade and the control of industry were based. We must be prepared for and endeavour to create a new technique in economic government. Mr. Lyttelton's emphatic vindication of the Government's economic policy as inspired by a comprehensive plan embracing the whole problem and clearly relating each part to every other should induce scientific workers to see that the framework of scientific co-operation and organization is adequate both to the demands of war-time and to the reconstruction to follow.

STARS AND ATOMS

The Birth and Death of the Sun

Stellar Evolution and Subatomic Energy. By Prof. George Gamow. Pp. xv+238+16 plates. (London: Macmillan and Co., Ltd., 1941.) 12*s*. 6*d*. net.

The World and the Atom

By C. Møller and Ebbe Rasmussen. Translated from the second Danish edition by Gerald C. Wheeler and Bernard Miall. Pp. 200. (London: George Allen and Unwin, Ltd., 1940.) 10*s*. 6*d*. net.

It is often alleged that men of science are culpably indifferent to the cultural and intellectual needs of the society in which they live and work. The tremendous uprush of scientific discovery during the last fifty years, an uprush which as yet shows no signs of abating, has raised social and intellectual problems which make it imperative that the man in the street should acquire some appreciation of scientific method and the results of its application, if only that he may be able to distinguish the true prophet from the charlatan. It has even been suggested by a recent correspondent to Nature that the education of the public in general, and of the leaders of public opinion in particular, may be the most valuable service which scientific workers can render the community.

If the charge of culpable negligence in the discharge of this duty was ever fairly levelled against men of science as a whole, which I must not stay to argue, a number of books have appeared within the last year or so of a quality and attractiveness which must at any rate secure an acquittal for the physicist. It is not very long since Gamow's "Mr. Tompkins in Wonderland" told the general reader all that he is likely to know of quantum theory and relativity; and wise folks who procured a copy of George Russell Harrison's "Atoms in Action" (see NATURE, December 14, 1940, p. 760) will have enjoyed an authoritative and admirable picture of the state of applied physics. The reader who, with appetite increased by what it fed on, asks for more, can be recommended to the books listed at the head of this notice, which deal with still other aspects of modern physics.

Gamow deals with some of the major problems of astronomy: Møller and Rasmussen with the riddle of the atom and its nucleus; the one with the infinitely large, the others with the infinitely small; but it is extraordinary how much ground the two books have in common. This is more than a coincidence. It is an illustration, and a very good one, of the essential unity of all research. A successful attack on one obscure part of the subject may lead to a sweeping advance all along the line; and the work of the 'atom-smasher' in the darkened laboratory has enabled the astrophysicist to write a new chapter in the history of the universe. The moral of this may be left for participants in the "Science and Politics" correspondence to draw.

Astronomy has always had its devotees. The mysteries of the heavens have always excited the wonder of mankind, and wonder is the legitimate parent of research. The question as to how the sun came into being, whence it draws its enormous supply of energy, and what is to be its ultimate fate must excite speculation and interest. Its solution, involving, as it does, the application of the principles of physics to conditions of temperature and pressure far exceeding anything available in terrestrial laboratories, demands the exercise of controlled imagination of the highest order. Some chapters of the story have already been written by Eddington and Jeans. Recent work on the transmutation of the elements begun by Lord Rutherford and now being extended by a host of physicists has added a new chapter to the tale. In brief, the extremely high-tension apparatus designed for 'atom-smashing' is able to give to a few particles a degree of energy of the same order of magnitude as that which they habitually possess in the interior of the sun. By hurling these high-speed particles at atoms of various kinds it is possible to study, on a very microscopic scale, reactions which must be going on, on an enormous scale, in the sun's interior. It is well known that energy on a large scale is set free in some of these reactions, and mankind has begun to look wistfully, but not very hopefully, to the day when it may be able to draw on this sub-atomic energy. It now turns out that our sun and its fellows have been tapping this great reservoir for ages.

It is an exciting story, and Prof. Gamow tells it extremely well. He has two great qualifications for the task. In the first place he has been closely connected with the work described, and gives to it all the vividness of an eye-witness's narrative. Secondly, he so obviously enjoys the story himself. The pursuit of a new physical problem clearly gives him all the fun and excitement of the chase, an excitement which he communicates to his readers. Prof. Gamow has a real flair for making difficult ideas appear simple, and an engaging sense of humour which not only breaks out in the text, but also illuminates the pictures and diagrams with which he has himself illustrated the book.

"The World and the Atom", by Møller and Rasmussen, is a scholarly account of the rise and progress of atomic physics from its inception at the beginning of the century to about 1938. The authors, one a theoretical the other an experimental physicist, are members of the Institute in Copenhagen presided over by Prof. Niels Bohr, who contributes a foreword. The book is a clear and well-balanced history of one of the great formative periods in science. The gradual introduction of new and ever-broadening conceptions into the structure of physics is clearly traced; and the essential parts played by the experimental physicist, the mathematician, and the technologist, and their reactions upon each other, are ably demonstrated.

In standard the book seems to lie somewhere between the entirely 'popular' and the elementary text-book. A student of modern physics would find it of value in co-ordinating his ideas, while the serious layman, wishing to gain an intelligent appreciation of one of the outstanding achievements of our age, should not find it beyond his powers. The book suffers a little from a certain heaviness in style which seems almost inevitable in a translation, but there is no lack of clarity.

Both books are excellently produced, and illustrated with diagrams and plates. Some of the Mount Wilson photographs of celestial phenomena reproduced in "The Birth and Death of the Sun" are a sheer delight.

J. A. CROWTHER.

RESEARCH ON MOTOR-CAR ENGINES

Collected Researches on Cylinder Wear
By C. G. Williams. Pp. vii+119. (London: Institution of Automobile Engineers, 1940.) 10*s.* 6*d.*

THE work being carried on at the research station of the Institution of Automobile Engineers at the Great West Road, Brentford, which was outlined in a description of the Laboratory in NATURE of November 23, 1940, is exemplified in the publication of "Collected Researches on Cylinder Wear", by C. G. Williams.

It is pointed out in the late Lord Austin's foreword that the problem of cylinder wear is one of the most serious with which motor-car manufacturers have had to deal. Individually, they have done much useful work towards its solution in their own laboratories, but owing to its complexity it was thought best to have it dealt with comprehensively by the Institution, and the several reports which constitute this publication confirm the advantage of this arrangement, not only in unifying the direction of the investigations but also in bringing together and releasing for general use the full range of information collected.

These collected researches include four interim reports on experiments carried out at the Institution's Laboratory, a discussion of published information on the subject, the collected experiences of manufacturers and operators giving the accumulated data prior to the adoption of the work at the new laboratory, a later report of more recent experiences and the results of an investigation of cylinder liner materials.

It had been suspected for some time that it was during the initial warming-up period that wear mainly takes place, but this partial knowledge led to an accentuation of the trouble as, in ignorance of the main source of wear, a wrong procedure was adopted. The contributory causes are many and various, associated as they are with mechanical and frictional conditions, the properties and chemical reactions of fuel and exhaust gases, high temperature, composition and structure of the metals in contact, influence of lubricating oils and so on. It is proved, however, that corrosion, not abrasion, is the main cause of cylinder wear, and there are several sources from which it may arise. Besides the action of water, which, as shown, can cause corrosion through oil films, there is the certainty of acidic conditions being produced from organic acids, sulphuric, nitric and carbonic acids derived in small proportions from the normal components of the fuel. The investigation of these miniature chemical processes will be found one of the most interesting phases of this series of researches, dealing as they do with many other complex and almost infinitesimal actions and reactions.

These researches were carried out with the view of making immediate use of the knowledge gained in the improvement of engines, and the report dealing with the more recent experiences of manufacturers and operators bears out their value. One improvement of major importance is the use of more suitable cylinder materials; special reference is made to nitrogen-hardened cast iron with its resistance to abrasive wear, and to austenitic cast iron, which can withstand both corrosive and abrasive wear. On many other points, this section gives details of the practical results which have accrued from the work of the Laboratory.

AGRICULTURAL PRODUCTION IN UGANDA

Agriculture in Uganda
By the Staff of the Department of Agriculture, Uganda. Edited by Dr. J. D. Tothill. (Published by authority of the Government of the Uganda Protectorate.) Pp. xvi+552+30 plates. (London: Oxford University Press, 1940.) 20*s.* net.

THIS is a comprehensive volume of information contributed by the staff of the Department of Agriculture in Uganda on agricultural conditions—including native agriculture, land tenure, soils, manures—imported, artificial, green and cover crops; climate, crops and allied subjects. The important associative sciences of mycology and entomology are also dealt with very thoroughly, the fungus and insect pests being discussed at length under each crop, though bees and locusts are treated in a separate section.

Under "Native Agriculture: Development of Ox-Cultivation", it is recorded that chiefs in Budama were first instructed in the use of the plough in 1909 and a ploughing school was started in 1910 at Kumi (in Teso). The first ploughs used in Teso were wooden, made locally from an Indian pattern; but, these, it is stated, were soon discarded in favour of European iron ploughs. Various types of these appear to have been tried, and the one most in favour at the present time is Ransome's "E.C.A." Other implements, ox-cultivators, etc., have been tried, but they do not appear to have come into general use. The tillage operations after the plough are still done by hand, which, the author of this subject states, is "one of the limiting factors to increased acreage of cotton by means of the plough".

It is not possible within the limits of this notice even to enumerate all the plants grown; but a few details of the main items may be mentioned, the production of which is fully discussed under various headings, mainly: "Native Food Crops: Sweet Potatoes, Cassava and Yams; the Cereals—'Bulo' (*Eleusine*), Maize, Sorghum, Rice and Wheat; Ground Nuts, Simsim (seed of *Sesamum*) and the Pulses—Pigeon Peas, Cow Peas, Tepary, Soy and Haricot Beans."

Fruits and vegetables are given a special section covering pp. 485–495. The most important fruits of Uganda, it is stated, "have been introduced, many are cultivated by the Natives for their own consumption and for sale in the markets of the towns." The principal fruit is the banana, to which a whole chapter is devoted (pp. 111–125). Some particulars are given of citrus fruits, the mango, avocado pear, guava, pine-apple, papaw and passion fruits; the record concluding with an extensive list of miscellaneous fruits, tropical and temperate, introduced into Uganda.

Under "Vegetables"—indigenous pot-herbs, wild yams (*Dioscorea*), etc., introduced tropical—okra (*Hibiscus*), egg-plant (*Solanum*), peppers (*Capsicum*) and chayote (*Sechium*) are cultivated. Among temperate vegetables grown at higher altitudes it is interesting to note the potato (*Solanum tuberosum*), many varieties of which have been imported during the last twenty years, mostly from Kenya, and now grown for sale to Europeans and for local native markets. It thrives at elevations of about 6,000 ft.—notably in Bugishu and Kigezi, where the crop yields well and has become an important foodstuff. Tomatoes are extensively produced and onions, shallots, etc., are cultivated on native farms. Cabbages and cauliflower are common in Buganda where they are major market-garden crops. In general it would seem that most European vegetables can be grown at suitable altitudes.

These developments in the production of foodstuffs, especially fresh fruit and vegetables, are of great importance in view of the recent investigations into pellagra—a deficiency disease—carried out by the medical officers in tropical Africa.

The main crops grown on a plantation on a commercial scale are coffee—robusta and Arabian; cacao, para rubber, tea, sugar and tobacco. The fibre plants, cotton and sisal only appear to have reached export standard among other fibres introduced and under trial. The history and development of cotton is given in full under Section viii, pp. 183–288, the importation of varieties for trial beginning about 1903–1910, the industry developing until, as the author states, "Uganda now competes with the Sudan for second place among the cotton producing countries of the British Empire, with a crop lately exceeding 300,000 bales." Sisal—first introduced in 1903—was not grown in commercial plantations until 1929, when an estate was established at Masindi Port, whence in 1936, 1,500 tons were exported. Other fibres that are or have been under trial include Mauritius hemp, sunn hemp and ramie or China grass.

Oil yielding plants (Section xiv) include cotton seed—50,000 tons average for five years (1930–35) shipped from Mombasa. Oil palm (*Elæis guineensis*), a native of West Africa, is also found wild in Uganda near the Congo border. The oil is not exported; but the cultivation is suggested for both pericarp and kernel oils as "a useful addition to native diet, which is poor in fats." Shea butter nut (*Butyrospermum parkii*) is found in the northern parts of Uganda, where the oil from the seeds is used for cooking; but neither nuts nor fat are exported. Tung oil (*Aleurites* spp.) native of China, and candle nut (*Aleurites moluccana*), native of Malaya, are under trial. Lemon grass (*Cymbopogon citratus*), introduced from Kew about 1901, is stated to be the only essential oil plant grown on a commercial scale in Uganda, and other essential oil plants that appear to be still under trial are geranium (*Pelargonium* spp.), patchouli (*Pogostemon* spp.) and vetiver (*Vetiveria zizanioides*). In 1929 a study of all the available essential oil plants was carried out by the botanical and chemical sections and the conclusion they came to was that: "at the present it is unlikely that the commercial production of essential oils will become important in Uganda."

Spices and drugs, native and introduced are discussed in Section xv., pp. 457–466: Of the native spices it is stated: "Few if any of the plants indigenous to Uganda have been used as a source of spice." The introduced plants, mostly under trial except where otherwise stated, are the well-known spices—peppers (chillies or red pepper—*Capsicum* spp.)—naturalized; cinnamon, cloves, turmeric, ginger—well established, but not grown as a commercial crop; and vanilla—cuttings introduced from Ceylon in 1912, now being produced on a commercial scale on a plantation at Entebbe. As to native drugs, there appears to be little information available and those introduced are all more or less under trial: areca nut palm, cocaine plant, quinine bark, wormseed (*Chenopodium*) and *Hydnocarpus* spp.

Included in the same section (xv), tans, dyes, gums and resins are briefly dealt with in less than two pages. The bark of two native trees, *Acacia spirocarpa* and *Terminalia velutina*, is used locally for tanning; wattle bark (*Acacia decurrens* var. *mollis*)—native of Australia, is used by the natives as a wind-break, for building-poles and for fuel in Kigezi, where it has been planted in large quantities but owing, it is said, to high cost of transport, the bark is not exported. Specimen trees of "Tara" (*Caesalpinia spinosa*) and "Divi-divi" (*C. coriaria*) —pods are an important trade tanning material from the Colombian Andes—are under trial. Of dyes it is remarked: "Few native plants have been used to any extent for dyeing for there is no native cloth weaving or fine leather industry as in West Africa." Of gums and resins the author states: "Many native trees produce gums but the trade in such products has never been large." Specimens of various exotic gum and resin producing plants are growing at Entebbe including balata, gutta-percha, chicle gum and benzoin; "all grow quite well but none shows prospect of being commercially important in Uganda."

The final pages of the text treat respectively of "Cover-Crops and Shade Trees", "Fruits and Vegetables" (mentioned in this note under Foods), "Grasses and Grazing"—including "Weeds", "The Marketing of Native Produce" and "Agricultural Education and Extension Work". Excellent indexes to scientific names of plants, of insects and general, conclude the book.

Agriculture at the present time in practically all countries is of paramount importance, especially so in the tropics, whence come many of the raw materials—rubber, fibres, oils, etc.—to quote a few examples only, on which our great manufacturing centres depend. Sisal hemp for example, in its use for binder-twine for harvesting machinery, may mean in every yard of its manufacture the saving of a loaf of bread, and in production and use it probably ranks second to cotton, which is regarded as the world's greatest industrial fibre and the most important of all agricultural products in international trade. When the ruling powers come to take stock of the resources on an international scale after the present world's disturbance of trade and transport, such works as the one now under review, based on many years experience, will not be found wanting.

The authors are to be congratulated on producing a very useful and handy volume, more readily accessible than the official agricultural technical papers and bulletins in which, as stated by the editor in his introduction, "much of the information has been published", and as foreshadowed by him, calculated to "enable those who are interested in the present state of Agriculture in this part of Africa to obtain reliable data quickly".

J. H. HOLLAND.

ESSENTIALS OF INTERVIEWING

The Psychology of the Interview
By R. C. Oldfield. Pp. xv+144. (London: Methuen and Co., Ltd., 1941.) 5*s*. net.

IN recent years psychologists have come increasingly to realize that the proper conduct of an interview is one of their basic techniques, whether it is used for supplementing experiment or as itself the chief tool of inquiry. Some parts of Mr. Oldfield's brief study bear on the psychological nature of interviewing in general, but in spite of its comprehensive title the book is in the main limited to the interviewing of candidates for employment, in itself an important enough topic to justify the closest study.

Part of the book offers sensible practical suggestions as to the setting and conduct of interviews. They represent a pooling of the practice of several experienced interviewers whose methods Mr. Oldfield was allowed to observe. The current practice, however, is not merely recorded but is also assessed from the psychological point of view, and Mr. Oldfield writes with good insight into the social situation created by interviewing. The total picture he presents, familiar though its details are, will be found illuminating even by experienced interviewers.

But Mr. Oldfield's chief interest is clearly theoretical. He is concerned to give an exact psychological description of the processes in which interviewing consists. In the first place he argues convincingly that each interview must remain a unique social situation, manipulated and interpreted by the interviewer according to his personal skill and intuitive insight. That is to say, the interview must be an achievement of personal craftsmanship and cannot be turned into a standardized experimental situation in which the only variable is the candidate. This is probably true of the type of interview Mr. Oldfield is discussing, where conversation is relied on almost exclusively, but it may need to be slightly modified if one considers interviews where the candidate's approach to standardized tasks, such as performance tests of intelligence, is systematically observed for the light it throws on temperamental qualities.

A useful theoretical contribution is the insistence that conversation, the texture of the interview, consists in a mutual modification or manipulation of attitudes, and that the exchange of information and specific opinions is only subsidiary, a means to the evocation of attitudes. This is in line with the growing recognition that the relative importance of cognitive experience and verbal behaviour has for long been exaggerated. Mr. Oldfield's view, however, is in danger of becoming too abstract to be useful when he reduces the interviewer's entire activity to the evocation and perception of attitudes in the candidate. This view of the matter cannot be said to be untrue, since all human activity expresses itself in a sequence of attitudes. But it ignores the important question of what feature of the candidate's personality a given attitude chiefly reflects ; whether, for example, a broad temperamental quality or a particular sentiment. The importance of interests is also rather slighted. Interests, temperamental qualities and sentiments are obviously closely connected and, of course, reveal themselves in attitudes, but they must be distinguished if the interviewer is to understand the significance of the attitudes he perceives in a candidate.

Although Mr. Oldfield's conclusions are not to be accepted without qualification, his effort towards a radical understanding of the interview as a psychological tool is nevertheless of very real value.

A BIRD OBSERVER IN CORNWALL

Winged Company
Studies in Bird-Watching. By R. G. Walmsley. Pp. xiii+227. (London : Eyre and Spottiswoode, Ltd., 1940.) 7*s.* 6*d.* net.

IT is a coincidence that I should be able to review this attractive bird book, because, not long before his death, the author wrote to me. In his letter he mentioned that he had been reading a book, "Wild Birds in Britain", which I had written about that time, and he had been, he said, greatly impressed by the resemblance between that book and the manuscript he had written. He said he felt that he might well have been the author of my book, and he felt he must write and tell me this lest, if ever his manuscript should appear in print (he was very doubtful of this at the time) I should know that he had not been copying my own style and treatment of the subject.

"Winged Company" is written by a true lover of birds, for as with Edward Grey of Falloden, birds were his great joy during the last years of his life. The birds he watched so lovingly, and with such accuracy, were mainly observed in Cornwall. Raven and chough, peregrine and buzzard, gannet and kittiwake, shearwaters and terns, and the tribe of the divers, among the larger species ; redwing and fieldfare, wheatear and skylark, the tribe of the warblers and the clan of the buntings among the smaller species. I was interested to read the author's statement that willow warblers "take a particular pleasure in tormenting Long Tailed Tits : they are like mischievous little boys chasing a party of fussy old ladies". I wonder if other observers have noted this.

He loved the wood warbler, which arrives "at a time when the beech leaves are most silky and diaphanous and the woods are filled with cool green lucencies". But surely the colour "beneath the wings of the Redwing" is not "scarlet" but rather cinnamon (p. 65). It is interesting to know (p. 70) that the first wheatear arrives on the Cornish coast during the first days of March. In the Isle of Skye it is the last week in that month before he is seen (the males always arrive first). I write this notice on April 12, yet I have seen no wheatear, and were he here he would be shivering under the lashings of an Arctic wind. I like the author's description of the male wheatear (p. 70):

> "The male Wheatears at this period are brilliantly arrayed ; pearl-grey, black, white, and a tint somewhere between salmon and apricot blend to produce a plumage of exotic beauty. . . . There is surely something Egyptian in the Wheatear's expression, a suggestion reinforced by its colouring, by the black and white fan of its tail, and by the bird's strange instinct toward the sand."

This book is one which will appeal to all those who love birds. The author's style is direct, simple, and bears distinction. For war-time days of paper shortage it is admirably reproduced. It is indeed a book to be read slowly, at leisure, to be fully appreciated, and the more one studies the wood-cuts by Denys Watkins-Pitchford, which form the illustrations, the more one is impressed by their accuracy. I like especially that showing buzzards circling over Zennor Cliffs (p. 195), but that of the peregrine's stoop at Rock Doves (p. 201) is fully its equal, and shows minuteness of observation and delicacy of delineation.

SETON GORDON.

PLANKTON AS A SOURCE OF FOOD

By Prof. A. C. Hardy, F.R.S.
University College, Hull

SIR JOHN GRAHAM KERR recently asked a question in the House of Commons and wrote a letter to *The Times*[1] proposing that a committee of biologists and engineers should be instituted to inquire into the possibility of obtaining food direct from the marine plankton.

One of the most surprising results of the "Discovery" investigations was the demonstration by Mackintosh and Wheeler[2] that the great rorquals, the Blue and Fin whales, became sexually mature and reach an average length of 75 ft. and 65 ft. respectively in *only two years* from birth; they are born 23 ft. and 21 ft. long after some eleven months of fœtal life. This prodigious mammalian growth, including the formation of great food reserves in the blubber, is built up entirely on a planktonic diet. It would certainly appear worth while to inquire if some of this wealth of food could not be taken directly from the sea to be used, if not for human consumption, as a valuable addition to the food of stock.

It is just fifty years since the late Sir William Herdman described in NATURE[3] how plankton formed a breakfast dish for a yachting party of eight. Johnstone[4] gives the following composition of the dry substance of copepod plankton: protein 59 per cent, fat 7 per cent, carbohydrate 20 per cent, chitin 4·7 per cent and ash 9·3 per cent. Gunther[5] found the oil content of zooplankton collected from the Isle of Man to vary between 15·05 and 19·3 per cent of dry weight.

No doubt a good deal of preliminary work would have to be done to see if the yield would be sufficient to warrant the cost of power and labour in its harvesting and preparation. Even if it was not an economic proposition for peace-time, the urgent need for food in war-time might put the matter in quite a different light.

Dr. George Clarke, of the Woods Hole Oceanographic Institution, wrote an article on the subject just before the War[6]. "According to a recent news report", he writes, "the German State Biological Institute at Heligoland is investigating the possibility of harvesting the plankton of the sea as a new food source for the German market to make Germany still more independent of foreign imports. Zooplankton was reported to have a nutritive value equivalent to the best meat and phytoplankton to be equal to rye flour."

Clarke considers that one might take "as an outside figure" a value of 0·1 gm. dry weight of plankton per cubic metre of sea water and that 750 gm. would be required to support one man per day assuming all the organic matter in the plankton to be assimilable. On this basis "each member of the population would require all the zooplankton from *at least* 7,500 cubic metres each day . . . . Using the largest net generally found practical (2 m. in diameter) at a fast towing speed (2 knots) and assuming a 20 per cent straining efficiency for a coarse net, a period of 2½ hours would be necessary to filter this volume of water. If several nets were used simultaneously, more men and larger boats entailing greater operating costs would be required." He ends his article by saying: "We are forced to conclude, therefore, that if the marketing of plankton on a commercial scale is to become a practical reality, either areas of greatly increased richness must be located or some method must be found for making the above rate of procuring plankton economically feasible."

Clarke's view of the matter might indeed have appeared discouraging had he not added the following footnote: "There might be some possibility of operating economically a filtering plant in a tidal flow between suitably located islands or in the entrance of an estuary." Here may well be the starting-point for such an experiment; if it should be successful, we, in the British Isles, are extraordinarily well placed for such an enterprise.

Up the west coast of Scotland there is an exceptionally rich plankton, richer than that upon which Clarke based his calculations, a plankton which supports the shoals of Loch Fyne herrings, attracts the basking sharks to the Firth of Clyde and has fed the rorquals which in years past made a whaling station in the Hebrides a paying proposition. In many of the long sea lochs, teeming with plankton, there is a strong tidal flow. In English estuaries huge tidal 'filter nets' have been used successfully by fishermen for generations. The sprat and whitebait fishermen of the Thames Estuary use 'stow nets' 200 ft. in length and having an opening of 20 ft. × 30 ft.; each net is streamed below a boat at anchor and is fastened by its bridles to the anchor chain. In the Bristol Channel (at Weston-super-Mare and Clevedon) nets with an opening 18 ft. square are streamed from the anchor chains of buoys so that they will swing as the tide turns. These nets are described in detail in that fascinating work, "An Account of the Fishing Gear of England and Wales"[7], by the late Mr. F. M. Davis.

A swing net such as the last mentioned could be made of stramin (a strong openly woven fabric in common use for the collection of the larger zooplankton) supported by the application of longitudinal and transverse lengths of rope. It would have an opening of 30 square metres. Taking Clarke's estimate of a filtering efficiency of 20 per cent, it would filter 22,278 cubic metres of sea water per hour in a 2-knot tide way. The pressure on the net could be reduced by fitting a conical opening to the entrance of the net to cut down the water entering to suit its filtering efficiency, as in Hensen's plankton net. It could swing with the tide and fish in both the flow and the ebb. The 'cod-end' could be hauled up and emptied of the catch at slack water by two men in a small boat. In many positions in the Scottish sea lochs one could count on the equivalent of a tidal flow averaging 2 knots for at least 12 hours a day. The net could be fished near the surface at night and deeper during the day to accord with the diurnal vertical migration of the bulk of the zooplankton. It could be made to turn and fish inside out and so be reversed at each emptying of the cod-end in order to prevent the meshes becoming clogged, as they would if it were constantly used in one direction.

Ten such nets fishing for 12 hours would yield 267·3 kgm., or 5¼ cwt., *dry weight* of plankton a day, or enough to feed 357 people. It would seem likely that the very rich plankton off the west of Scotland might give an even higher yield than this, which is based on Clarke's estimate of 0·1 gm. dry weight of plankton per cubic metre of sea water.

If tests for yield could be made this summer with a few such nets placed at different points in the Scottish sea lochs and if at the same time researches were undertaken into the food values of the plankton and the best means of making it available for either human or animal consumption we might in time for next summer know if it would be worth while launching a large-scale effort to increase the country's food supply.

More than a thousand miles of drift nets were used in our herring fishery in the days of its prime. The herring grounds are now largely closed and the boats and crews otherwise employed. If trials were found to justify the above calculations, a hundred 'fleets' of tidal nets (each of ten nets looked after by two men) would yield 26¼ tons of plankton *dry weight* per day from the sheltered waters comparatively safe from enemy action. The plankton could be transported by boat or road to factories for its treatment at suitable points along the coast. Such a war-time emergency measure might well give rise to a regular peace-time industry. With practice the efficiency of the methods could be increased and perhaps in time it would be economically feasible to employ special ships to harvest the still richer plankton of the polar seas.

Sir John Graham Kerr's request that a committee should be set up by the Ministry of Food to inquire into the possibility of obtaining food from the plankton should not lightly be turned aside. In his question in the House of Commons he referred to modern types of mechanical separators; it would be important to investigate whether these would be more economical and efficient than the use of tidal nets.

NATURE OF THE INTRAMOLECULAR FOLD IN ALPHA-KERATIN AND ALPHA-MYOSIN

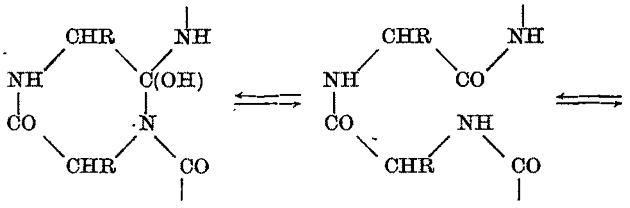
By Dr. W. T. Astbury, F.R.S., and Dr. Florence O. Bell,

Textile Physics Laboratory, University of Leeds

KERATIN, the protein of mammalian hairs and related epidermal tissues, the fibrous proteins of the epidermis itself, and myosin[2], the principal protein of muscle tissue, all fall into one great group of fibrous proteins that have a common molecular configuration and similar long-range elastic properties. This generalization follows from a series of X-ray and supporting investigations that have been described among other places in NATURE[1]. There will perhaps be no need then to summarize them again here, beyond recalling that the structural unit of the group is a 'grid' consisting of long polypeptide chains cross-linked by means of their side-chains, that the main-chains of this grid are not normally in the extended configuration but are thrown into a sequence of folds transverse to the side-chains, and that when the fibres are stretched the grid is pulled out flat, only to return to its folded configuration when the tension is released. The normal folded configuration we have called α, the extended configuration β, and the reversible intramolecular transformation from α-keratin (or α-myosin) to β-keratin (or β-myosin) is the basis of the remarkable long-range elastic properties of this group of protein fibres.

The chemical constitution of the group changes unmistakably as we pass from keratin on one hand to myosin on the other, though the main features (not the fine structure) of the X-ray diffraction pattern remain always the same, especially the strong meridian reflexion of spacing about 5·1 A. Even without the confirmatory evidence of the elastic and other properties, this is sufficient to demonstrate convincingly that there is some intramolecular conformation common to the whole group, something analogous to the benzene ring, say, in aromatic chemistry, that overrides within limits variations in empirical constitution. The implication, of course, is that the conformation in question is the intramolecular fold responsible for the long-range elastic properties, and it is a matter of stereochemical urgency, for the great keratin-myosin group in particular and for proteins in general, to discover its exact nature.

Our earlier theory was that the transformation involves the opening of hexagonal rings, thus :



ALPHA

and more recently Wrinch has developed the same idea systematically into her 'cyclol hypothesis'. But now the tide of evidence is flowing strongly against it [3, 4], and especially the experiments of Neurath[5] with up-to-date scale models have shown conclusively that there is simply no room for the side-chains when the main-chains are folded in this way. It seems that we have to accept the fact once and for all and bend ourselves to seek a new solution.

The β-configuration may be represented diagrammatically as in Fig. 1. There is no stereochemical difficulty about it; the side-chains lie alternately on one side and the other of the main-chain, well out of one another's way. The unstretched, or α-, configuration is formed from the β- by throwing the main-chains into a series of regular folds (in terms of Fig. 1 these folds undulate above and below the plane of the paper), and the operations of extension and contraction leave the integrity of the grid unchanged.

Now put as concisely as possible, the experimental and general structural conditions[6] to be satisfied by the α-β transformation are as follows :

(1) The α-form must be about half as long as the β-form.

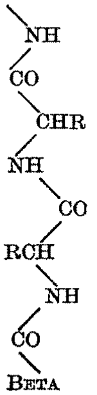
(2) The density must remain practically constant.

(3) The folds must repeat at a distance of about 5·1A.

(4) The side-chains must stand out alternately on one side and the other of the plane of the fold.

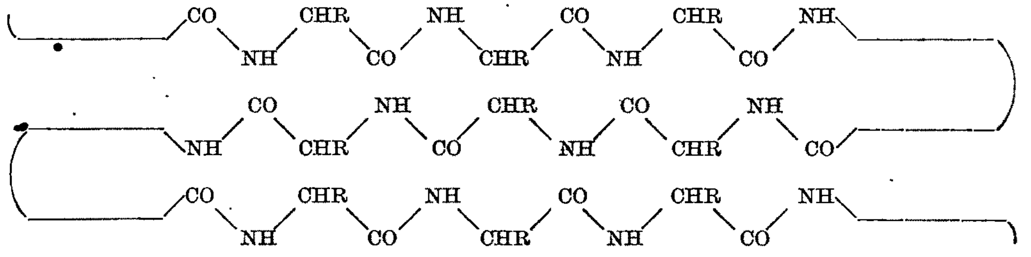
(5) The folds must be nowhere so sharp as to leave insufficient room for the side-chains.

Is it feasible to devise an intramolecular fold satisfying all these conditions that could conceivably, pending complete chemical analyses, be adapted equally well to the constitution of myosin as to that of keratin ? We believe that it is ; and what is more, the proposed solution hints at a principle fundamental for all proteins.



BETA

Consider condition (2). It is really nothing new or unique, for almost all proteins have densities in the neighbourhood of 1·3, the density of wool keratin. This order of density is what we should expect for a parallel polypeptide chain system in the β-configuration[7], and the fact of its being observed again in the corpuscular (or globular) proteins, both before and after denaturation[8], provides one of the best arguments we have in favour of regarding these proteins also as effectively fibrous. The inference is that folds in polypeptides are in general of the following type[9] :



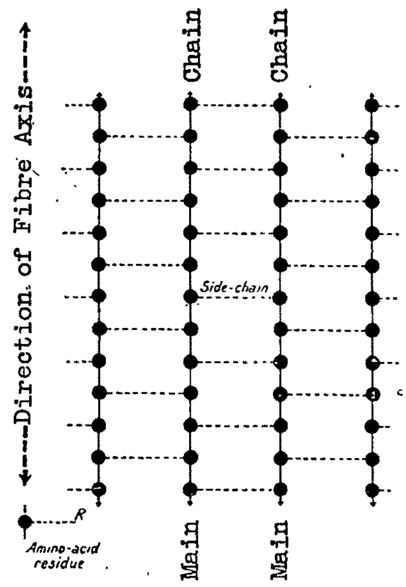


Fig. 1.

A POLYPEPTIDE 'GRID' IN THE β-CONFIGURATION.

with the side-chains projecting alternately above and below the plane of the folds.

If now we try in this way to accommodate the other conditions, we find at once with the aid of models that 5·1 A. *is just about the shortest distance at which it is possible to fold a polypeptide chain so as to leave the side-chains alternately on one side and the other of the fold*, and further of course, if the fold is approximately square, it doubles its length too when opened out. We have thus satisfied the first four conditions, and there remains only to examine more closely the fate of the fifth. Actually, *the side-chains are seen to be grouped in close-packed triangular columns first on one side of the fold and then on the other.*

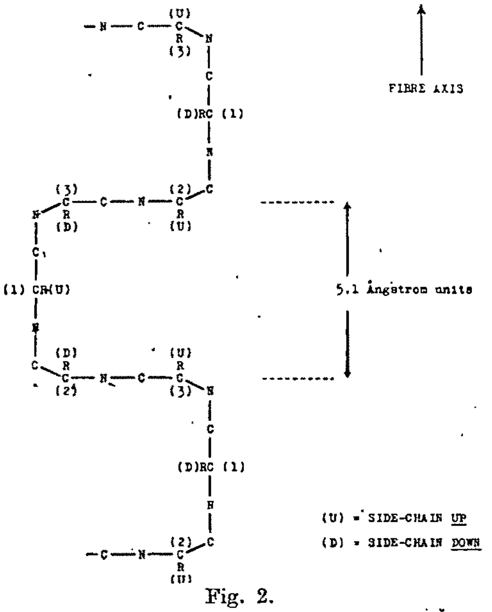

Fig. 2.

PROPOSED BASIS OF THE INTRAMOLECULAR FOLD IN α-KERATIN AND α-MYOSIN.

The sequence of amino acid residues and the inter-relations of the side-chains are shown diagrammatically in Figs. 2 and 3, while Figs. 4*a* and 4*b* are photographs of an atomic model, built to scale[10], of one fold and part of the fold adjacent to it. In Fig. 4*a*, which illustrates the packing of the side-chains and corresponds to that part of Fig. 3 surrounded by a dotted line, the large spheres represent the second CH_2-group counting from the main-chain (assuming for our purpose side-chains at least two carbon atoms long), but in Fig. 4*b*, the other face of the model, the side-chains have been removed to reveal the form of the main-chain. The diagrammatic square has been distorted somewhat so as to build a 'hydrogen bridge' between opposing CO- and NH-groups within the fold, and it has also been found necessary, in order to meet the dimensional requirements of the X-ray photographs, to postulate hydrogen bridges between adjacent folds. Altogether, the arrangement seems very satisfactory indeed—in fact the various atoms and groups fit together so neatly that it is scarcely possible to construct the model in any other way if the five basic conditions are to be observed. A particularly nice point is this, that the shortest permissible width of fold is rather greater than the distance of closest packing of alkyl chains, and therefore the tendency to close packing is slightly in excess of what we need: conceivably it could fold the backbone a little tighter still, but the bounds are set just before that—and so the *main* pattern always repeats at the same distance, 5·1 A. As soon as the side-chains leave the confines of the backbone they presumably cling together rather more closely, and if they want to open out again

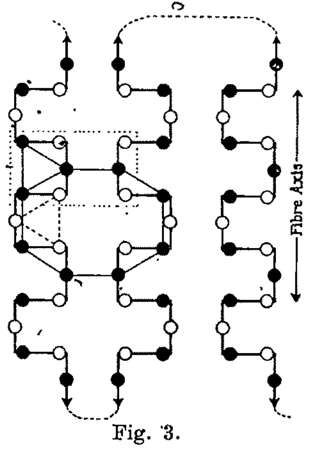

Fig. 3.

ILLUSTRATING THE CLOSE PACKING OF SIDE-CHAINS IN THE α-FOLD OF KERATIN AND MYOSIN.

—represents the direction of the main-chain; ● represents a side-chain pointing *up* from the plane of the diagram; ○ represents a side-chain pointing *down* from the plane of the diagram.

somewhat to allow for the bulkier of the terminal groups, they can do so by making use of the octagonal gaps in the structure (see Fig. 3).

The above solution of the keratin-myosin problem has been obtained by induction, but the more correct treatment would appear to be by *deduction* from the principle of close packing. The principle is familiar enough in structures built from ions and small molecules, but it must apply also to the mobile parts of single large molecules, such as the side-chains in proteins. We should like to put it forward here, in fact, as probably one of the great general principles of protein structure. It leads immediately, for example, to the present solution of the keratin-myosin problem, for obviously the arrangement shown in Fig. 3 is one of the first we should arrive at. No longer need we be surprised at the remarkable 'accident' that β-keratin is just about twice as long as α-keratin and has just about the same density: we see now that *these supposed conditions are inevitable consequences of close-packing the side-chains in a simple, regular pattern.*

The accompanying table summarizes the comparative chemical constitutions of wool keratin and rabbit myosin as derived with the help of X-ray data in the manner already described in this journal[11]. The table is frankly idealistic, incomplete and tentative in parts[12]; but in any event it is obvious that the two proteins differ considerably in empirical constitution. There must therefore be a certain interchangeability, or rather potential interchangeability, between the residues forming one structure and those forming the other, an intramolecular counterpart of mixed crystallization[11]. Provided a residue is of the right 'type', apparently that is all that matters, within limits.

COMPARATIVE CHEMICAL CONSTITUTIONS OF KERATIN AND MYOSIN

Amino acid	Proposed numbers of residues of each amino acid in a total of 576	
	Wool keratin	Rabbit myosin
Glycine	64	48 (?)
Alanine	32	48
Valine	24	24
Leucine, etc.	64	64
Phenylalanine	16	16
Proline	36 (or 32)	3
Methionine	3	16
Cystine/2	72 (or 64)	8
Serine	64	48 (?)
Threonine	32	48 (?)
Tyrosine	16	18 (?)
Tryptophane	6	3
Aspartic acid	32	48
Glutamic acid	64	96
Arginine	36 (or 48)	32
Lysine	12	48
Histidine	3	8
Totals	576	576
Residues as amides	64	64
Average residue weight	118	116 approx.
Molecular weight	68,000	67,000

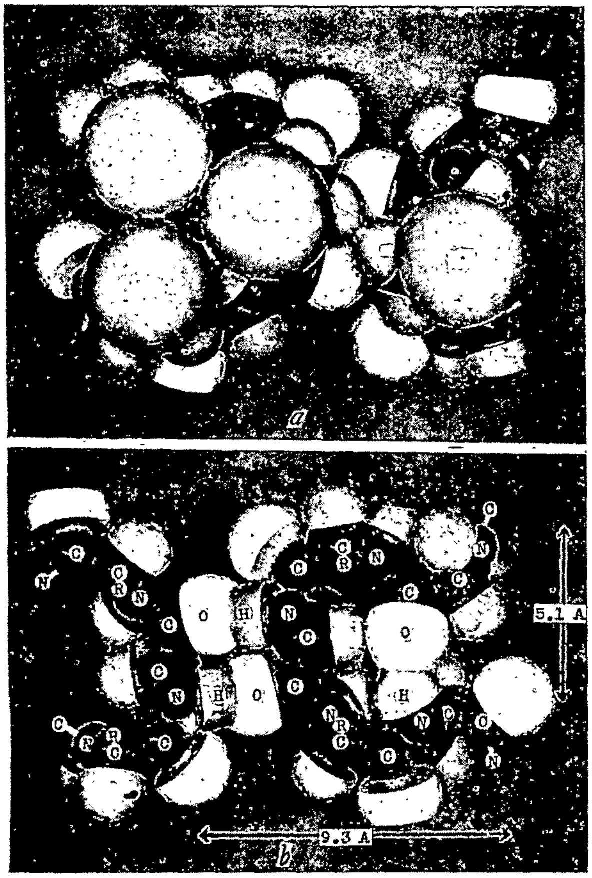

Fig. 4.

The great lesson of the keratin-myosin group is that a protein is essentially a pattern of charges associated with a close-packed forest of side-chains, the polypeptide chain being an infinitely variable device for building up distributions of charges and presenting them to given chemical environments. A typical, though not necessarily universal, unit of protein architecture is a sheet (or ribbon) of folded main-chains with side-chains projecting from either face. Several years ago (also in the pages of this journal) we gave strong reasons for supposing that the native egg albumin molecule consists of four such sheets superposed[13]. The further developments of the keratin-myosin theory outlined in this article only tend to confirm the suggestion.

THE CIVILIAN POPULATION UNDER BOMBARDMENT

BY R. J. BARTLETT,

KING'S COLLEGE, LONDON

A MEETING of the British Psychological Society was held at Nottingham during April 17–21 and, among other matters, dealt with the effects of war conditions on the civilian population. In particular, Dr. Margaret Lowenfeld introduced the problem of man in the mass, while Dr. H. Crichton-Miller set out the effects on the individual of air bombardment. Discussion emphasized that more should be done by psychologists in air-raid shelters and evacuation areas, and a further meeting will be held to consider the whole situation.

Man in the aggregate shows behaviour that cannot be foretold from the study of man as an individual; but there is little that ranks as scientific knowledge of such behaviour. Many assumptions about mass behaviour derive from introspection, the study of animal behaviour and from psychopathology. The inadequacy of such a basis is witnessed by the breakdown of the theory that, brought to its senses by the horrors and foolishness of 1914–18, mankind would replace savage war by civilized consultation; and by the fact that loudly heralded 'panic' has, so far, failed to materialize.

There is scarcely any acceptable published material on which to base decisions of such practical importance as the kind of shelters human beings prefer: whether deep or surface, noisy or quiet, small or large. We do not know the conditions that promote or hinder courage, or how best to protect children. We do know that groups of the population behave peculiarly; that in some areas old men and women refuse removal to safety from nightly bombardment, that panic does not occur where physiologically it should, and that noise is more frightening than bomb destruction to some, while it is comforting to others.

With the same people nightly in the same shelters, subjected to events varying from mere boredom to the horrors of an inferno, almost laboratory conditions are provided for testing theories of instinctive activity and volitional control. Such an opportunity ought not to be neglected by social psychology. Concerted effort should be made to secure unbiased psychological truth and to put it to practical use. It is time that factually based reasoning and planning were given a chance to displace 'trial and error' methods.

The official explanation of absence of panic under bombardment and presence of the 'we can take it' attitude would seem to be our much-applauded morale. Therein lies a danger. Moral courage eliminates self-pity and malingering, and, if functional disability is due to these, it is something to be ashamed of and despised. But functional disability resulting from air bombardment is a serious reality and has nothing whatever to do with morals. In the War of 1914–18 the functional effects of high explosives were clearly recognized and labelled shell-shock. For various reasons it was decided to cut out shell-shock from the present War. However, the naïve conviction that a symptom can be eliminated by forbidding it a name broke down. The symptom reappeared and clinicians named it blast-concussion.

The incalculable effect of blast on plate-glass windows is a commonplace. It is reasonable to suppose that similar effects of compression and suction on elastic abdominal walls displace the fluids of the body with extreme violence to and from the skull-contained brain. The strain thus imposed upon the delicate structure of the central nervous system is very severe and in fatal cases punctate hæmorrhages are found, *post mortem*, not only in the meninges but also throughout the brain substance.

Blast-concussion, in varying degrees of severity, is to be expected after exposure to an explosion. It bears no relation to morale, courage, discipline or any other ethical virtue, and has no intrinsic connexion with psychology. Extrinsic association is, however, very common. The effects on a person suffering from acute anxiety differ from those on one knocked out with 'no time to be frightened'. A hysterical person will exploit the effects in the same unconscious or semi-volitional way in which other disabilities are exploited. An alloy of organic concussion and emotional fear is common. Each factor should be dealt with, and the assumption that all unwounded patients are malingerers should be carefully avoided. The obviously wounded person is in a relatively happy position. He is ensured the rest essential for cure of concussion, and spared the feeling of loss of prestige from being disabled without visible trauma. Thus the worst effects of blast-concussion are seen in the unwounded.

Consider next physiological conditions influencing air-raid reactions. An exhausted man, with his supply of blood sugar at fasting level or below it, reacts badly to fear of death or danger. Anæmia and anoxæmia lead to despondency, apathy and inertia on one hand and to mental confusion and uncontrolled behaviour on the other. Toxæmia lowers the whole resistance of the organism. With women there is also the varying emotional effects of the menstrual cycle, lactation and the climacteric. Again, in reaction to fear there is the influence of the adrenal glands. Normally fear produces an adrenal response which mobilizes available glucose, increasing muscular tone and enhancing activity which issues in 'fight or flight'. In troops about to attack, aggression should be at a maximum; but with civilians exposed to bombardment the natural reactions of 'fight or flight' are inappropriate, and fortitude, endurance, self-control are needed. In the first we have an instinctive pattern of behaviour, in the second a civilized pattern of conduct. In the absence of opportunity for retaliation or escape a severe strain is placed upon the efficiency of cortical control. Fear of death or suffering is endured in a latent or overt way. If latent it constitutes anxiety, if expressed we call it hysteria. The hysterical appeal drains off anxiety which has been accumulated by interference with the 'fight or flight' mechanism. Anxiety is the price man pays for a culture that demands inhibition of fear and hate reactions.

All this can be seen in the shelter situation under bombardment. Crude pugnacity in one man picks a quarrel with the shelter warden on wholly inadequate grounds. Flight reaction in another refuses the protection of the shelter and drives away, on and on, until the petrol supply is exhausted. In either case the breakdown of cortical control results in an instinctive reaction to fear. With realization that neither fight nor flight is a reasonable way out, the anxiety case, trembling and sweating, alert, taut and incapable of relaxation, scarcely controls himself as explosion follows explosion, while the hysteric in many ways proclaims the need of compassion, admiration or interest, and takes refuge in imagined protection of others. Still more common is anxiety-hysteria in which a limited control is unable to restrain a partial publicity campaign, but, nevertheless, succeeds in enduring a measure of unrelieved fear.

In many cases no one factor will fully account for the unhappy condition of the patient. A case was quoted where the recognized causes were: (1) dental sepsis, (2) gross ill treatment in childhood, (3) unfaithful marital life charged with guilt and fear. The elimination of any one of these factors would have modified the character of the breakdown. Each played its part in reducing a powerfully built, athletic man to a trembling, sighing, restless mass of anxiety when his house was demolished just after he and his family had taken cover in a public shelter.

OBITUARIES

Dr. Otto Pettersson

OTTO PETTERSSON, chemist, physicist and hydrographer, was born in Gothenburg in February 1848, and died there on January 16, 1941. He took his degree at Uppsala in 1882, and began work as an inorganic chemist, studying selenium and beryllium while his friend Theodor Cleve was studying the rare earths; but he soon turned to physical chemistry, which was coming to the front just then, and had a long paper in NATURE on a "New Principle of Measuring Heat", in 1884, nearly sixty years ago (NATURE, **30**, 320; 1884). Heat phenomena in general, specific heats, latent heats and heats of crystallization, led him towards hydrography by way of the temperature and ice-conditions of the Baltic and Arctic Seas; and he got his chance when Nordenskiöld brought the *Vega* home and asked him to report on the hydrography of the Siberian Sea. A careful determination of the maximal density-point of sea-water at various salinities formed part of this report, and the work brought him into contact with John Murray, and with Tait, who was then busy with the temperature observations of the *Challenger*.

Pettersson had a family place at Holma, in Bohuslan, where the Baltic was at his very door, with all its fascinating hydrography. F. L. Ekman had made a good start towards its investigation, but there was plenty left to do; and Pettersson with his friend, Gustav Ekman, wrote one paper after another in the early 'nineties, mostly on the hydrography of the Skagerrak. Two problems interested him then and ever after. Where ocean water enters the inland sea it dips down and lets the fresh water float out above the salt; each has its own phenomena, and the submerged surface of discontinuity is the seat of waves and tides which may reach considerable amplitude. Under such conditions as these Nansen had encountered 'dead water', and Wilfred Ekman had explained that old mystery once for all; our submarine commanders were mightily perplexed by the same stratification when they first entered the Skagerrak in the beginning of the War of 1914–18; and here Otto Pettersson found what he called the Gulf-stream water' rolling in, deep down, invisible.

The second problem, closely associated with the first, lay in the vicissitudes of the Swedish herring fishery. For Bohuslan had been the seat of the great Hanseatic herring fishery in the thirteenth and fourteenth centuries, until it came to a sudden end in the fifteenth, and moved out, to the enrichment of Holland, into the North Sea. Pettersson found an explanation of this great historical event (and of certain other catastrophies such as the formation of the Zuyder Zee) as part of a long-period phenomenon, due to hydrographical and, in turn, to astronomical tide-producing conditions. At a certain rare configuration of sun and moon, he said, great underwaves rolled into the Baltic from the ocean, and brought the herring where they now no longer come. At the same time the fresh waters were reduced to a shallow surface-layer, so apt to cool down and freeze that severe winters and a frozen Baltic were a common thing. All this work of Pettersson's is extraordinarily interesting; but it is very complex and very difficult, and perhaps the time has not yet come to judge it.

Pettersson and his friends were pioneers of oceanography, and it was they who brought a little company together in Stockholm, in 1899, to plan the international "Exploration of the Sea". Nansen was there, and John Murray and Otto Krümmel; Cleve was there, once a famous chemist, now one of the chief students of the micro-fauna of the surface of the sea; Gustav Ekman came from Gothenburg and Victor Hensen from Kiel and Friedrich Heincke from Heligoland; and Johann Hjort and Martin Knudsen and I who write these lines were among the younger men. It was an honour and an education to be there.

Otto Pettersson lived two happy lives, as farmer and as scientific man. "I am a peasant," he was wont to say; it was the only English word he ever mispronounced. When I once paid him a visit at Holma he had some sixty or seventy beautiful Frisian cows in his model dairy, and he had lately built his laboratory on a little rocky island just over the way. The cliff went sheer down, and the workroom actually overhung the deep water of the Gulmarfjord. The little place was full of gadgets; water could be pumped from various depths, and all sorts of recording instruments ticked away. A copper vessel floating on the surface of discontinuity rose and fell with the submarine waves, and transmitted their motion to a recording drum. In fact, the devising of apparatus was one of Pettersson's special gifts, perhaps his greatest gift of all; the water-bottle which goes by his name and Nansen's was really his. Nansen, for all I know, may have somewhat improved it, and he used it and made it known; but it was Otto Pettersson who made it first, and gave it to Nansen to take with him on the *Fram*. Pettersson was fertile of ideas, ingenious in experiment, enthusiastic over all he took in hand to do. Age did not wither him. He kept his sturdy frame, his active mind, his warm heart, his cheerful countenance, even to extreme old age.

D'ARCY W. THOMPSON.

Mr. Francis Druce

MR. FRANCIS DRUCE, who was killed recently by enemy action, was well known as a botanist and collector of botanical books. He was born on January 3, 1873. Educated at Harrow and Magdalen College, Oxford, he entered the long-established firm of Druce and Attlee. In 1910 he was forced by ill-health to retire from active participation in the business (from which he completely retired in 1923), and his great love of "Nature in all her moods" led his energies into the study first of meteorology, then of his chief interest, botany. His legal experience, good judgment and methodical habits made him an ideal treasurer of scientific societies to which he belonged. In this capacity he served the Royal Meteorological Society for two periods, 1913–1918 and 1925–1932. He was treasurer of the Linnean Society of London from 1931 until the autumn of 1940, when he became master of the Innholders' Company, of which, following the family tradition, he had previously been clerk for some years. Of the Botanical Society of the British Isles he became treasurer a few years before his death, and also took over the secretaryship when the secretary was called up for active service.

Druce formed extensive meteorological and botanical libraries. The former he presented to the Royal Meteorological Society some seven years ago, but he continued meteorological observations until his death, and when travelling always carried with him a maximum-minimum thermometer. His botanical library, except for most of his rarer herbals, was in great part destroyed in the fire which followed his death: it has been the subject of an article in the "Private Libraries" series of the Times Literary Supplement (Dec. 31, 1938). His herbarium, which mainly consisted of British plants collected by himself during the past twenty-five years, and which included almost every British species which it is possible at the present time to see in native haunts, was completely destroyed. Since 1919 I have visited most parts of the British Isles in his company, hunting rare desiderata, these ultimately becoming reduced to the 'forlorn hopes' of almost or quite extinct species. He was intrepid on rocks, and appeared quite comfortable standing on the edge of a cliff examining the slopes below through his field-glasses, which he generally carried to observe birds, of whose song (as also of good music) he was a great lover. He acquired a very good knowledge of the British flora and had a good eye for plants, although he himself never tackled any of the critical genera and preferred others to write up the results of his expeditions. He remained unmarried, but took great interest in the boys' clubs of his parish church in Chelsea, of which he was a strong supporter. Generous and loyal, he will be missed by a wide circle of friends.

A. J. WILMOTT.

Dr. C. G. Lamb

WE regret to record the death of Dr. Charles George Lamb, emeritus reader in electrical engineering in the University of Cambridge, on May 4.

Born in 1867, Lamb originally wished to become a professional musician; when the early death of his father made this impracticable, he went to the University of London, where he attended courses on zoology, and for a time contemplated a medical career; but he ultimately decided to study electrical engineering at the City and Guilds College, where as a student he helped to test the first alternating current transformer that was brought to Great Britain. After graduating, Lamb went to Cambridge in 1891 to assist the late Sir Alfred Ewing in his researches on the magnetic properties of iron; in the same year he was appointed University demonstrator in mechanism and applied mechanics, a post which he held until he was appointed University lecturer in electrical engineering in 1903.

During the War of 1914–18, Lamb acted as head of the Department of Engineering; and thereafter, in 1921, the post of reader in electrical engineering was created for him, and ceased to exist on his retirement from reasons of health, in 1931. During the forty years he was teaching in Cambridge, Lamb watched and helped the growth of the Engineering Laboratory from insignificant beginnings to one of the largest departments of the University, and he is remembered with gratitude and affection by generations of students.

One of Lamb's distinguishing characteristics was his versatility; his interests and knowledge of matters remote from his own particular work were astonishingly wide. He could hold his own in discussions on such diverse matters as history, medicine and psychical research, so that experts in each subject were astonished when afterwards told that the man to whom they had been talking was not a specialist in their own line of research. His encyclopædic knowledge, practical ability, and readiness to take any amount of trouble whenever his help was asked were of great value to his friends, and to the University, especially in his capacity of a syndic of the University Press, an office to which he was repeatedly elected for many years.

Lamb spent most of his spare time in collecting and studying insects. He specialized on the flies, working for some years with Dr. David Sharp, and such was his ability in this direction that he became a recognized authority on certain groups of the Acalypteræ, especially the Ephydridæ and the Drosophilidæ, describing many new species. He was a real naturalist, and was a mine of information on the habits and life-histories of the insects he studied. His most important research was the study of the Diptera of the Seychelles, of the 428 species of which 28 genera and 311 species were previously unknown. He also did most valuable work in the Insect Department of the University Museum of Zoology, where he was in effect honorary curator of the Diptera for many years. For his zoological work, the University conferred upon him the degree of Sc.D. in 1923, and on his retirement from the Engineering Laboratory in 1931 he was created emeritus reader in electrical engineering.

Lamb never lost his early interest in music; although of late years even his most intimate friends could seldom prevail on him to play to them. As a freemason, he was a well-known figure in both town and University, and attained high rank. As a lecturer, he sometimes failed to appreciate that his mind worked faster than that of any but the most able of his audience, but he never grudged the time to explain privately any difficulties. To Cambridge zoological research he was for twenty years the valued referee whenever mathematical conceptions were involved. No student, colleague or friend ever asked his help in vain.

C. R. C.

Mrs. Beatrice Bateson

THE recent death of Mrs. Beatrice Bateson, widow of William Bateson, F.R.S., has meant more than the loss to her own immediate friends. A link with the past has been broken, and many of his former pupil and colleagues will recall the integral part she played in those memorable days at Grantchester or Merton—a Saturday afternoon, a Sunday lunch—where the sense of intellectual freedom and curiosity, the spaciousness and the humour, were of her making as well as of his. She was always there to help, whether it was Japanese prints, embroideries, a display of home art, the chicken-pens or the greenhouses that formed the absorbing interest of the moment.

In recent years, when her own talents and her own energy had to stand alone, Mrs. Bateson's labours were mainly threefold; she made her garden in Sussex a delight, and with her needle she produced embroideries of great beauty of design and execution. But more important than trowel or needle was her piano; even within a few months of her death, under able and kindly guidance, she was mastering the intricacies of Bach with the enthusiasm and intensity of youth.

To Mrs. Bateson is due the biographical sketch of her husband, published in 1928: "William Bateson, F.R.S., Naturalist, His Essays and Addresses, together with a Short Account of his Life", which must form an important work of reference to some future biographer.

Of their sons, the eldest was killed in the War of 1914–18, and the second died in London shortly after. Gregory Bateson, the anthropologist, now working in America, is the youngest and only surviving son. Mrs. Bateson was the third daughter of Dr. Durham.

Her single-minded devotion to the things of the mind will remain embodied in the memory of her music-room in Sussex—the adapted bakehouse of the small Mill House. Two grand pianos of the smallest size could just fit in; on the window-sill stood a pot or two of her orchids, while one window looked straight into her beloved miniature greenhouse. On the walls and in the book-cases were many treasures, ranging from Blake to the Chinese, each eagerly acquired in the early days, each loved for its own sake and for its associations. In that room was no place for ignorance or for idleness.

WE regret to announce the following deaths:

Mr. E. O. F. Brown, president of the Institution of Mining Engineers, on May 22, aged fifty-nine.

The Right Hon. Lord Cadman, G.C.M.G., F.R.S., Chairman of the Anglo-Iranian Oil Company, Ltd., and the Irak Petroleum Company, Ltd., emeritus professor of mining and petroleum technology in the University of Birmingham on May 31, aged sixty-three.

Prof. Oskar Loew formerly professor of plant physiology in the University of Berlin, aged ninety-seven.

Dr. R. Campbell Thompson, F.B.A., Shillito reader in Assyriology in the University of Oxford, on May 23, aged sixty-four.

NEWS AND VIEWS

The Right Hon. Winston Churchill, F.R.S.

UNDER a statute of the Royal Society which provides for the election of persons who either have rendered conspicuous service to the cause of science or are such that their election would be of signal benefit to the Society, the Right Hon. Winston S. Churchill was elected a fellow of the Royal Society on May 29.

The admission of the Prime Minister to the Royal Society, although to some extent in accordance with precedent, is in Mr. Churchill's case thoroughly justified by his interest in, and appreciation of, scientific developments. Time and again, in speeches in the House of Commons and in broadcast addresses, he has stressed the importance of making the fullest possible use of science to combat the "perverted science", as he has rightly termed it, of Nazism, which has been nurtured for the purpose of destroying life and property and enslaving the souls of men. He was quick to appreciate the use which was being made by our enemies of scientific developments, and equally swift to realize that scientific men in Great Britain have the knowledge and skill to counter their attacks. Moreover, he has not hesitated to pay public tribute to their work, as witness his statement in the House of Commons when he proclaimed the defeat of the magnetic mine, which for a few weeks had taken a heavy toll of our ships. This awareness of the significance of scientific developments culminated in the appointment last October of the Scientific Advisory Committee, to which reference has frequently been made in these columns, whereby the leading research institutions of the country are enabled to maintain direct contact with the Cabinet itself. Mr. Churchill's election to the fellowship of the Royal Society is a timely recognition by the world of science of his services to the British Empire, to the cause of democracy and not least to the cause of science itself.

The Royal Society: New Foreign Members

PROF. J. B. CONANT and Dr. K. Landsteiner have recently been elected foreign members of the Royal Society.

Prof. J. B. Conant, For. Mem. R.S.

PROF. JAMES BRYANT CONANT held the position of professor of chemistry and head of the Chemical Faculty at Harvard up to 1933, when he was elected to the high office of president of the University. In relinquishing his post in the Department of Chemistry, although the University as a whole gained, American science lost to a large extent one of its most distinguished investigators. Nevertheless, Prof. Conant never abandoned chemical research, and has published original work continuously up to the present time. His researches cover an impressive range of subjects, and are especially noteworthy by the novelty of the physical chemical approach and the skill with which this has been employed in the field of organic chemistry. Although it is impossible adequately to indicate the scope of his work in a short summary, some idea of his versatility can be gained by mention of some of the major themes. These include: (*a*) A comprehensive study of the addition of phosphorus halides to organic compounds in the course of which entirely novel reactions were brought to light; (*b*) Numerous publications dealing with the study of oxidation-reduction potentials of organic compounds, including hæmin and related substances; (*c*) Investigations of free radicals and the kinetics of their formation; (*d*) The application of physical methods to structural problems of organic chemistry; (*e*) The study of reaction mechanism as applied both to substitution displacements and keto-enol tautomerism; (*f*) Researches on the constitution of chlorophyll and the related porphyrin groups; (*g*) Biological-chemical applications of induced radioactive indicators.

In all his numerous publications one is struck with the freshness of outlook with which Prof. Conant approaches the subject. His intuitive faculty and deep insight into the fundamentals are matched by notable experimental skill. The work with which his name is most clearly associated is that relating to the constitution of chlorophyll. In this field his contributions have been outstanding; he cleared up many of the more obscure points in the structural relationship of the chlorophyll group, and contributed matter of the highest originality. His work is entirely independent of that of Hans Fischer and, although not so extensive in scope, certainly of equal merit. To specify a few major examples of his chlorophyll work one might cite the fact that he was the first to provide conclusive evidence of the close connexion between the green derivatives of chlorophyll and porphyrins. Similarly, his work on the 'allomerization' of chlorophyll is peculiarly fascinating; he was the first to recognize it as an oxidation, a discovery which led directly to a complete understanding of this complex phenomenon. He initiated with Prof. Kistiakowski the important series of exact measurements of the heats of organic reactions which the latter has been carrying on up to the present time. Since his appointment to his present office he has devoted his energies and talents to raising the standard of teaching and research in universities, and to promoting liberty of thought and expression. Prof. Conant has also had a considerable influence on the development of the organic chemical industry in the United States, and in this connexion it is worthy of note that his scientific initiative as a consultant was an important factor in the success of Carothers's work on new polymers. Finally, during the past three years he has devoted as much of his time as his many duties would permit to educating public opinion in the United States to appreciate the full value of maintaining a true democratic outlook, and his present appointment by President Roosevelt testifies to the success of his efforts and the confidence the latter has in him.

Dr. K. Landsteiner, For. Mem. R.S.

WORKERS in the field of medical research in Great Britain will wish to join in congratulating Dr. Karl Landsteiner, of the Rockefeller Institute in New York, on his recent election, and will regard the honour as being a well-merited tribute to the high level of the scientific work he has pursued with unremitting vigour during the past forty years. Three outstanding achievements will forever be associated with his name: the discovery of individual differences in human blood which account for the four well-defined groups; the demonstration, together with E. Popper, that the causal agent of acute poliomyelitis is transmissible to monkeys; and the series of notable contributions he has made towards elucidating the nature of the specificity of immunological reactions.

Dr. Landsteiner was an assistant in the Institute of Pathology of the University of Vienna when, in 1901, he first published his work on iso-agglutination and the blood groups. Even at this early date he was aware of the probable significance of his results for medico-legal purposes, and in the practice of blood transfusion; and the value of his pioneer researches on the subject was attested when, in 1930, he was awarded the Nobel Prize in Medicine. The two first papers on the experimental transmission of poliomyelitis to monkeys appeared in 1908 and 1909, and they pointed the way to the subsequent intensive study by himself and by many other workers of the mode of transmission of the causal virus and of its neutralization by a specific immune-serum. In later years Landsteiner and his collaborators have been occupied chiefly with the chemical aspects of immunity. Their investigations and, in particular, the ingenious experiments with artificially conjugated antigens and the corresponding immune-sera have shed much light on the nature of the serological specificity of proteins and cell antigens.

Plankton as a Source of Food

THE interesting article which we publish in another column (p. 695) is of special importance inasmuch as it is from the pen of a distinguished leader in the investigation of marine plankton and its distribution. As the first occupant of the chair of zoology in University College, Hull, Prof. Hardy has wisely borne in mind its proximity to the great fishing-port of Grimsby, and has directed the policy of his department along lines which, as he believes, will lead towards increased prosperity of the fishing industry. The ingenious apparatus which he has devised for towing behind a moving vessel and registering a continuous record—quantitative and qualitative—of the plankton present along the route traversed is well known to all interested in plankton research, and it may well be that the not distant future will see this apparatus installed as part of the regular equipment of vessels engaged in the fishery of those important food-fish—such as herring, pilchard or mackerel—which, subsisting on particular types of plankton, tend naturally to concentrate where their favourite food happens for the time being to be most abundant.

Prof. Hardy, on the whole, supports Sir John Graham Kerr's plea for the appointment of an expert committee to examine into the practicability or otherwise of drawing upon the plankton directly for the reinforcement of the food supply of Great Britain. He emphasizes the nutritive value of plankton. He quotes chemical analyses, which we find perhaps less impressive since an encounter many years ago with a destructive beetle larva which was able to subsist upon a diet of dry cork, and out of it—in apparently complete defiance of all dietetic principles—to build up living protoplasm indistinguishable chemically from that of a human being. But Prof. Hardy tells us too how not long before the outbreak of war, German researchers reported upon two different types of plankton as being respectively equivalent in nutritive value to 'the best meat' and to rye flour. Finally, he quotes the case of the whalebone whales, and, unmindful of the reminder conveyed in a charming leading article in *The Times* regarding their ungainly portliness, the more seriously directs attention to the extraordinarily rapid growth of the young whale as incontrovertible evidence of the nourishing qualities of its food. The practical suggestions made by Prof. Hardy in regard to the large-scale collection of plankton, are, in view of his special knowledge, worthy of attention, and no less so his hint that the preliminary stages in the working out of the plankton-food problems might well be undertaken during the present summer.

Coastal Plankton of New South Wales

PROF. W. J. DAKIN has been working for nine years at the study of plankton off Sydney Harbour. The difficulties were many, but a great deal has been accomplished which acquires a deeper significance when one realizes that it is the preliminary to further fisheries researches in the future. A small yacht only was available, but with this, fortnightly samples of plankton with accompanying hydrographic data (the last only for the first three years) were taken almost continuously. The results, which include much original work not published elsewhere, are now available ("The Plankton of the Australian Coastal Waters off New South Wales. Part 1." Publications of the University of Sydney. Department of Zoology. Monograph No. 1. By William J. Dakin and Alan N. Colefax. 1940). There is, however, much more in it, for it is a general guide to Australian plankton indispensable to all who study the subject in these waters, the introductions give a good survey of each group, and almost every organism is described and, in most cases, figured. Lists of relevant literature are given at the end of each section and certain specialists have helped in identifications. Mr. Takasi Tokioka's contribution on the Chætognatha with its beautiful figures is noteworthy. Mr. Alan Colefax is responsible for the large and detailed section on the Copepoda and also for the chemical analyses.

Prof. Dakin is the author of the main part of the work. Among the Crustacea his notes on life-histories are valuable, especially among the Decapods. The larval stages of the Australian Decapods are little known, and this is obviously an extensive field for research. Larval Thalassinids form a large part of the plankton, especially inshore. "In one quarter-hour haul at Broken Bay in April 1935, there were hundreds of thousands of larvæ in different stages." Gurney, in the "Discovery" Reports (1938), has shown that there are many more Thalassinid larvæ than known adults (especially belonging to the Axiid-Callianassid group). Here again in Sydney Harbour the adults are not known, except in a very few instances. The larvæ occur at certain stated times. It will be interesting to hear of more researches on these forms—a difficult subject, as these Thalassinids live in very inaccessible places, and there must be an enormous number of undescribed species. The present work deals mainly with invertebrates, but there is a small section on fish eggs. Further work on these and on other groups here not fully dealt with are subjects for the future.

War-Time Medicinal Formulæ

THE direction of the policy which is being adopted in the compilation of war-time formulæ for medicinal preparations is indicated by the nature of the recommendations recently made by the British Pharmaceutical Codex Revision Committee. It may well be that there is little need to replace all those drugs now unobtainable by alternative substances. On the other hand, it is very desirable that authoritative guidance should be given to prescribers as to substitutes for at least some of the scarce or unobtainable drugs, and also as to the best combinations in which to present them. This duty falls upon several bodies recognized as being properly constituted for the purpose, and one such is the Codex Revision Committee.

The recommendations made by this body are not restricted to the replacement of scarce substances by those which are more freely available. They cover a wider field. Thus it is proposed to authorize the use of tap water in place of distilled water except in injections and in preparations for which the pharmacist may consider distilled water more suitable. To the patient who invariably uses tap water to dilute his medicines, where dilution is directed, there appears to be nothing remarkable in this recommendation and there would seem to be little reason why it should not continue to be applied in peace-time. With regard to alcohol the Committee, following the advice of the Medical Research Council, that, in order to observe economy in the use of alcohol, many tinctures should be replaced by concentrated preparations, agrees that concentrated liquid extracts should be employed instead of tinctures and has decided to draw up a list of liquid extracts which might be used for this purpose. Other recommendations have their origin in the scarcity of tragacanth, squill, liquid paraffin, olive oil and almond oil.

Food Growing and Utilization

IT is fully recognized that the amateur gardeners and allotment holders of Great Britain are making a vital contribution to the war effort. Maximum crops need to be raised and any wastage through faulty storage or cooking must be avoided. The "Penguin Book of Food Growing, Storing and Cooking", by Mr. F. W. P. Carter, provides much practical information in a simple manner on these subjects (Penguin Special, S.90. Harmondsworth: Penguin Books, Ltd. 6*d*.). Crops are dealt with alphabetically which makes reference simple. The method of cultivation, recommended varieties, quantity of seed required, likely pests and their control, storage and where possible also cooking methods are described for all the more commonly grown vegetables. Good general information is also given regarding the preparation of the soil. The booklet concludes with simple suggestions for garden work each month and a detailed cropping plan for a period of three years on a typical allotment.

The correct utilization of food is dealt with by Mr. Frank Wokes in another Penguin Special, "Food: the Deciding Factor" (S. 87. 6*d*. Much information on food values and diet is compressed into a small space. The energy and body-building values of different types of food are explained, and diets suggested which make for properly balanced meals, rationing being taken into account. A considerable part of the booklet is devoted to the question of vitamins, the quantities required and the foods which supply them. Interesting tables are given in the appendix showing the body-building and energy values, mineral and vitamin contents of a large number of generally consumed articles of food, including cereals, dairy produce, fish, fruit, meat and nuts.

Institute of Physics: Industrial Radiology Group

FOR some considerable time, physicists engaged in the various branches of industrial radiology have expressed a wish for some means whereby they could come together for the mutual discussion of their particular problems. Accordingly, the London and Home Counties' Branch of the Institute of Physics arranged a Conference on Industrial Radiography in January 1941 (see NATURE, February 8, p. 183). As a result of this Conference it was decided to ask the Board of the Institute of Physics to approve the formation of a Radiography Group. The Board's approval having been obtained, the inaugural meeting of the Group was held on May 20, at the Social Centre of Messrs. Kodak, Ltd., Harrow, about seventy people attending—some coming from as far afield as Leven, Motherwell, Sheffield and Derby. The title "Industrial Radiology Group" being approved by those present, Dr. L. Mullins, of the Research Laboratory of Messrs. Kodak, Ltd., was appointed honorary secretary, and the following committee was elected: Drs. W. Betteridge, D. W. Davison, and H. Lowery, Messrs. A. N. Gilchrist, W. L. Harper, H. P. Rooksby, H. S. Tasker, D. E. Thomas, and E. J. Tunnicliffe.

So constituted, the present committee is representative of those concerned with the industrial applications of radiography and X-ray crystallography and of those engaged in the manufacture of industrial X-ray apparatus and X-ray films. In addition, the British Institute of Radiology and the

Society of Radiographers are to be asked to send one representative each to serve on the committee. This committee was given power to elect its own chairman and to formulate a constitution for the Group. In addition to providing a medium for the exchange of views and experiences on the practice of radiography and X-ray crystallography in industry, it is to be hoped that the Group may ultimately issue a report summarizing many of the essential practical points of importance to users of X-ray plant, as one noticed at the above-mentioned Conference that many quite elementary matters of technique were not generally known in the various industries employing X-rays. Membership of the Industrial Radiology Group is open to all who are interested, whether or not they are at present members of the Institute of Physics.

Association of Scientific Workers

THE annual council meeting of the Association of Scientific Workers was held in Birmingham on May 24 and 25 ; eighty delegates were present representing scientific workers and engineers in industrial and Government posts as well as university staff and students. As this was the first council meeting to be held since the registration of the Association as a trade union, the reports presented, and the ensuing discussion, were chiefly concerned with the planning of an industrial policy for the Association. Discussion centred mainly around a report by the Industrial Sub-Committee which analysed the present conditions of scientific and engineering staff. This report showed that even under peace-time conditions, there is a considerable difference between salaries paid to people having the same qualifications but employed by different firms. In the engineering industry, for example, the general salary level is notably less than in certain chemical firms. Increments were often obtained by negotiation between the employer and the individual, but war-time restrictions on change of employment have removed the individual's chief bargaining instrument. A survey among members of the Association shows that there is a marked tendency in industry for no increments to be given, while in Government establishments war-time posts carry a fixed salary.

It was pointed out in the discussion that cancellation of increments is particularly unfair to the younger scientific workers whose salaries are frozen at the low starting figure. Attention was also directed to the injustices caused by failure to grant payment for overtime to many scientific workers and engineers. It was said to be a common experience, particularly in large firms, for hours of work and holidays to be altered suddenly without consultation with the unorganized sections of the staff. The conclusion drawn by the Industrial Sub-committee of the Association and endorsed by the council meeting is that collective action through the Association is the only effective method by which engineers and scientific workers can safeguard their conditions, and bring them into relationship with those of organized sections of industry. The council unanimously adopted a resolution in favour of close co-operation between the Association and other trade unions.

Mummification in America

REFERENCE has already been made (NATURE, April 5, p. 413) to the first part of a description by Dr. Aleš Hrdlička, curator of physical anthropology in the U.S. National Museum, of investigations undertaken in mummy caves and rock shelters in the Aleutian Islands off the coast of Alaska (*Scientific Monthly*, Jan.–Feb. 1941). It would appear that the aboriginal inhabitants were at some unknown period replaced by the Aleuts, among whom, comparatively lately, Russian penetration took place. The Aleuts practised mummifying, though whether they began to do so after their arrival in the islands or whether they brought the custom with them from their unknown place of origin remains a mystery. The mummies of both sexes were stored in the caves lying upon driftwood, and differences of physical anthropology among them suggest that a few members of the pre-Aleut people had been allowed to survive, perhaps in a condition of slavery. The finding of one or two objects of Russian origin with some of the mummies seems to indicate that the practice continued until a fairly recent date. A certain amount of cremation also appears to have been customary, and interesting and well-developed industries showing some degree of artistry were collected. The difficulties under which the expedition worked were very considerable, but nevertheless much valuable information has been added to our knowledge of these interesting peoples.

The practice of mummifying the dead, like that of trephination, is always intriguing. Why should these elaborate processes have been undertaken at all ? Connected as they often were with magic or religious notions, their discovery sometimes throws a side-light on the ideas of bygone peoples; whereas a study of the ordinary industries of such folk only determines their material culture—only tells us how they lived, not how they thought. Actually, mummifying has never been a common method of dealing with the dead either in modern or in ancient times. Egypt, of course, furnishes the classic example, but in the New World there were peoples both in South and North America who practised the rite. The orthodox diffusionist naturally claims that the custom in, say, Peru derived from Egypt; but frankly it is difficult to believe that the two or three prehistoric American peoples really had any connexion either with the Old World or with each other. It would seem far more likely to have been the result of a spontaneous development consequent upon a somewhat similar outlook on death.

Floating Electric Power Plants

MR. A. C. HARDY, in an article entitled "The Electric Ship" in the *Electrician* of May 2, outlines some recent trends and developments. A project for a 50,000 kw. self-contained, floating power plant is being studied by the General Electric Co., Schenectady. The plant is to be housed in a hull of similar dimensions to that of a Great Lakes freighter capable of passing through the Welland Canal, the dimensions being limited to 290 ft. by 43 ft., with a draught of 10 ft. and a low-bridge clearance of 15 ft. It is recalled that this idea is not new, for two 10,000 kw. turbo-generators were installed in the hull of the *Jacona*, a vessel built during the War of 1914–18, and since 1930 used as a floating power plant in New England. This vessel was taken in hand at the works of the Newport News Shipbuilding and Dry Dock Co. The main engine boilers and auxiliary formerly used for propulsion were removed. The funnel, foremast and four forward winches, propeller, shaft-tunnel and shafting were removed. New watertight bulkheads were installed fore and aft, and special thickening was fitted underneath the power plant. Two steam turbo-generators were installed, taking steam from four marine boilers, delivering 280,000 lb. of steam per hour at 425 lb. pressure at 250° F. superheat. The steam consumption of the turbines is about 9·4 lb. per kwh. at full load, the turbines being directly connected. With the exception of a few auxiliaries, the whole of the plant is divisible into two separate units, two boilers being arranged to serve each turbine. The method of making electrical connexion to the shore is a problem involving considerable study.

James Nasmyth as Tool Maker

WHEN James Nasmyth (1808–1890) was twenty-six years of age he set up in business as an engineer in Manchester, and two years later, at Patricroft on the Bridgewater Canal, he established the famous Bridgewater Foundry, so named after the Great Duke. By 1856, Nasmyth was able to retire and devote himself to astronomy. The foundry, however, was carried on successfully by others until July 1940, when it became a Government ordnance factory. One consequence of this was the presentation to the Institution of Mechanical Engineers, by Sir Holberry Mensforth, of Nasmyth's well-known "Sketch Book" and a portfolio of early drawings. Most of the drawings are of steam hammers, but others relate to machine tools. Some of these are of exceptional interest, and in *The Engineer* of May 23, Dr. H. W. Dickinson gives a review of Nasmyth's pioneering work in this department of engineering. As an appendix to the article a transcription is given of a letter written in 1864, in which Nasmyth refers to his discovery of the 'willow leaf' pattern on the sun's surface, a discovery which "has made a great stir among astronomers".

Activated Charcoals from Peat Residue

IN the tenth part of a series of "Studies in Peat", J. Reilly and J. R. O'Donoghue (*Sci. Proc. Roy. Dublin Soc.*, 22 (N.S.), 367; 1941) report experiments on the preparation of activated charcoals from peat. Before preparing the charcoal, waxy constituents were removed. Of various methods used, activation with superheated steam, and, to a lesser extent, by treatment with syrupy phosphoric acid before carbonization were found to be best for producing charcoals of performance approaching commercial standards. So far as is known, the peat residue is the first substance of Irish origin to be examined as a source of active charcoal.

Earthquakes in Turkey

THAT the earth's crust has not yet settled down after the disastrous Turkish earthquakes of December 1939 is evidenced by recent earthquake activity in that country. Minor shocks are frequently experienced, and stronger ones occur from time to time. Two such happened during the last fortnight. A strong earthquake on May 24 broke the sea wall at Mugla, opposite the island of Rhodes. Some other damage and twenty casualties have been reported at Mugla, and less intense shocks were experienced at Smyrna. During the night of May 30–31, a strong tremor was felt in Anatolia, causing serious damage to a large number of houses. No casualties have been reported as a result of this shock.

Announcements

PROF. L. J. MORDELL, F.R.S., Fielden professor of pure mathematics in the University of Manchester, has been awarded the De Morgan Medal of the London Mathematical Society.

DR. J. A. VENN, president of Queens' College, Cambridge, and Gilbey lecturer in agricultural economics and history, has been elected vice-chancellor of the University for the academical year beginning on October 1, in succession to Mr. E. A. Benians, master of St. John's College, who has held the office for the customary two years.

The Adams Prize for 1939–40, valued at about £268, has been awarded to Dr. Harold Davenport, assistant lecturer in mathematics in the University of Manchester. Dr. Davenport, who graduated as a wrangler, was formerly a fellow of Trinity College.

THE herbarium near Hudiksvall, in Sweden, containing thirty thousand specimens of roses, compiled and classified by the late Reinhold Matsson, the Swedish botanist, has been destroyed by a fire.

A NEW division of chemotherapy has been formed in the National Institute of Health of the United States Public Health Service to be under the direction of Dr. William H. Sebrell, jun. The new unit will be concerned with research on sulphanilamide products and with new synthetic drugs with antimalarial properties, in order to make the United States independent of the Dutch East Indies supply of quinine. The division will have quarters at the National Institute of Health in Bethesda, Maryland. The building will also be the headquarters of the divisions of chemistry and zoology.

ERRATUM. The title of the letter by Dr. H. L. A. Tarr in NATURE of April 5, p. 417, should read "The Bacteriostatic Action of Nitrites"; thus the work relates to "nitrites" and not to "nitrates" as printed.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

Further Correlation of Physical and Biological Properties in an Acridine Series

THE partition coefficients between olive oil and water of the five monoaminoacridines[1] have been investigated, and the results, set out in the accompanying table, include acridine and proflavine (2 : 8-diaminoacridine) for comparison.

The method followed was to dissolve the amine hydrochloride in a large excess of phosphate buffer solution (pH 7·0) and to shake this for two hours at 25° C. with sufficient acid-free olive oil[2] to extract approximately half the amine. The emulsion was centrifuged and the aqueous layer compared in a colorimeter with the unextracted solution. The latter was then diluted to the concentration found for the extracted solution, and the two were again compared in order to compensate for any deviation from Beer's Law. Finally where, as in the cases of 3- and 4-aminoacridines, there is a profound change of colour on acidification, both solutions were brought to pH 2·5 and again compared. Concordant readings were given by all methods. The concentrations of each amine at equilibrium were arranged to vary in different experiments, the aqueous layer containing 0·5–3·0 mgm. per 100 ml. in regular steps. In spite of this sixfold variation, no change in the coefficient was noted, indicating that association does not take place.

On account of the sparing solubility in water of acridine and 1-aminoacridine, it was necessary to devise a modified technique by reversing Farmer's procedure[3] for calculating the dissociation constant of an amine from its partition coefficient. Accordingly 1-aminoacridine was extracted by oil from its solutions in $N/100$ sulphuric acid and the aqueous layer (pH 2·1) compared with unextracted solution brought to the same pH value. The amount of amine in the oil was found by subtraction and was divided by the amount of free base existing in the aqueous layer at equilibrium as found from the equation :

$$\log\frac{[B]}{[BH]} = p\text{H} - 14 - \log K \quad . \quad . \quad . \quad \text{(i)}$$

which is derived from $\frac{[B][H]}{[BH]} = \frac{10^{-14}}{K}$,

$[B]$ and $[BH]$ representing concentrations of free base and its salt respectively.

Since salt-formation has been taken into consideration, partition coefficients calculated as above are comparable[3] with those found at pH 7, at which value 1-aminoacridine and acridine are almost entirely hydrolysed. Acridine, being almost colourless, was estimated by precipitation with excess picrolonic acid, filtration through fritted glass, and titration of the uncombined picrolonic acid with methylene blue[4].

It will be seen from the table that there is a correlation of physical and biological properties in this series in so far as the members most active against bacteria are the most basic and the most hydrophilic, whereas the least basic and most hydrophobic members have only feeble antiseptic properties.

	Partition coefficient oil/water	Dissociation constant, water, 25° C. × 10^{-10}	Bacteriostatic index[1]. (Sum total of inhibitory dilutions)	Average lethal dose (mouse)	Bactericidal value[5]
				gm./kgm.	
5-Aminoacridine	1	300,000	43	0·08	96
Proflavine	0·5	120,000	41	0·14	92
2-Aminoacridine	5	12,000	41	0·17	82
4-Aminoacridine	55	30	17	0·33	61
3-Aminoacridine	90	12	17	0·33	56
Acridine	250	2	12	0·30	Not tried
1-Aminoacridine	1200	1	8	0·91	49

The bacteriostatic index is quoted from a previous communication[1]. The average lethal dose ($L.D.$ 50) was found by subcutaneous injection of mice using 6–12 mice for each dose and interpolating for a 50 per cent kill after plotting the logarithm of each dose against the percentage killed. It will be noted that the mammalian toxicity rises with the bacteriostatic index, but as the latter figure represents powers of 2, it can be shown that the mammalian toxicity does not tend to rise on so steep a gradient as the toxicity to bacteria. The bactericidal values quoted in the table represent the percentage reduction of hæmolytic streptococci effected by a 1 : 10,000 concentration of the derivative in 10 per cent serum broth after two hours at 37° C.

The causes underlying the correlations are not yet clear. The hydrophilic properties of the strong bases are not due to the fact that they exist mainly as salts at pH 7. For example, 5-aminoacridine, which at pH 7 contains only 0·3 per cent of free base (from equation (1)), has its partition coefficient of 1 raised only to 3 at pH 10 where it contains 80 per cent of free base. Moreover the biological properties may be found to depend not so much on the basicity as on the various types[1] of amino groups which the basicities indicate.

The biological results quoted in this paper will appear elsewhere in greater detail[5]. Meanwhile 5-aminoacridine is undergoing clinical trial as a non-staining antiseptic with the general properties of proflavine.

'Crossed Fibrillar' Structure of Plant Cell Walls

THE so-called 'crossed fibrillar' structure observed in the walls of some plant cells[1,2,3] and inferred in a variety of others[4] still awaits explanation, and although the evidence for its presence in the latter cases can scarcely be considered satisfactory[5], this type of structure is sufficiently widespread to present a problem of the first magnitude in cell-wall physics. Several attempts have been made in these columns and elsewhere to define the underlying mechanism, and it is the purpose of this note to point out a new possibility which arises from the recent work of Astbury and Bell[6]. The importance of the organization of the protoplasmic surface in considerations of wall structure is now slowly being realized, and recent evidence[1] suggests that it is in this surface that we are to seek the mechanism involved in the regular alternation of chain orientation implied by the crossed fibrillar structure. Now in the recent emendation put forward by Astbury and Bell of what may be called the 'classical' model of protein structure, the fibrous proteins keratin and myosin are considered always to be *effectively* in the β-configuration whatever the state of folding [see Figs. 1, 2 and 3, p. 698 of this issue for diagrams of the α- and β-configurations; the supercontracted form would resemble the diagram given by Astbury and Bell for the globular proteins]. The contraction of the α- or of the β- form to the supercontracted condition now corresponds in this model to an effective rotation of the constituent protein chains to the transverse direction.

This type of folding surely gives expression to an underlying principle common to all proteins, including those in the cytoplasm-wall interface, and if we adopt the assumption now being formulated vaguely by some workers that the cellulose chains in a new layer may be oriented in a direction governed by the underlying protein chains, we have a ready solution of the present problem. The direction of cellulose chains may be alternated simply by alternate extension and contraction of the protein chain molecules in the protoplasmic surface. Confirmation of this idea will naturally not be easy. No single cell type has yet been worked out in sufficient detail, but evidence derived from a number of sources is already suggestive.

There are reported in the literature a few cases in which the cellulose chains of the primary wall in an elongated cell lie almost transversely and in later walls layers almost longitudinally[3]. Together with this we may put also the various observations that the physical properties of the cytoplasm in meristematic cells are often different from those in cells becoming adult. We have, for example, numerous statements that high metabolic activity is associated with low cytoplasmic viscosity[7], with one specific observation that in the hyphæ of Rhizopus (the wall of which is of chitin with a structure closely resembling that of cellulose) the viscosity in the growth zone is much less than elsewhere[8]. Changes in viscosity may, of course, be due to any one of a number of causes, but we do know that in some cases a change in fluidity is associated with changes in the configuration of a protein, for example, with contraction of muscle[9], and they are precisely what we should expect if, on passing from the meristematic to the adult state, the proteins in the surface are extending. Similarly we have some grounds for thinking that the *p*H of cytoplasm in a meristem may not be far removed from the isoelectric point of its constituent proteins[10], whereas in adult cells it lies near the point of neutrality. It is well known that proteins are *p*H sensitive and that in some cases *p*H change, though not the causative factor, is associated with muscular contraction[8].

The contraction and extension of the protein chains is naturally to be considered as occurring, or at least being initiated, locally; it has no effect on the external appearance of the cell, the shape of which continues to be controlled by the surrounding cellulose envelope. It is difficult to be precise at this stage, particularly with cells like Valonia, Chætomorpha and Cladophora, where the crossed fibrillar structure manifests itself most markedly. It may be significant that changes in cytoplasmic viscosity often accompany nuclear division.

Chemical Substitutes for Dietary Protein

THE stimulating article by Dr. Benesch on the utilization of non-protein nitrogenous compounds as protein substitutes which was recently published in NATURE[1] is a timely contribution to an important subject. At the outset, Dr. Benesch explains that his object in writing the article is to show that "the problem has reached a practical stage". This opinion is, however, by no means shared by all those who have studied the voluminous literature on the subject published (mainly from the Continent) during the past twenty years. In fact the attitude of Krebs, who reviewed the subject exhaustively in 1937, is in many respects diametrically opposed to that of Dr. Benesch. Moreover, it is all too frequently found that the same set of results is accorded entirely opposite interpretations according to the particular outlook of the workers concerned.

In view of this conflict of opinion, and having in mind the probable war-time shortage of feeding-stuffs, a group of research workers at the Hannah Institute began, about two years ago, a series of experiments designed to reinvestigate the value of urea and ammonium salts as protein substitutes for milk production. An endeavour was made to plan the details of the experiments with sufficient care to ensure that the final results would not readily lend themselves to alternative interpretations, due to the inclusion of inadequate controls or to the recording of incomplete experimental data.

The programme of work finally adopted was twofold. In the first section of the work lactating cows were fed on a diet which was just adequate according to present accepted feeding-standards and which contained a protein of first-class biological value for milk production. This was compared with the same diet in which one third of the protein of the production ration was replaced by urea. Milk yields, body weights, nitrogen balances, creatine-creatinine excretion, milk composition and the partition of nitrogen in the blood were all studied.

In the second section of the work, use was made of a steer with a large rumen fistula to determine, both by *in vivo* and *in vitro* methods, whether protein synthesis could actually be observed in the rumen contents, and, if so, what were the major factors affecting the magnitude and efficiency of such synthesis. In this work the research group was able to secure the valuable co-operation of Mr. Frank Baker of Guildford, who for some years has devoted much time to the study of the microflora and fauna of the rumen and cæcum of Herbivora.

It is hoped that the detailed results of much of the work will be available for publication within the next few months. The two most important findings may meantime be stated tentatively and briefly as follows: (1) Urea, which was first rapidly converted into ammonium salts in the rumen, proved to be of unquestionable value as a partial substitute for protein in the feeding of dairy cattle, *provided that it was fed in proper amounts and in a suitable mixture.* It was readily eaten by the animals and was without ill effects either on their general health or on the yield and quality of their milk. (2) In the course of *in vitro* incubations of rumen contents in which the general conditions of the medium and the microbiological picture (so far as it could be judged) were similar to those in the intact rumen, the conversion of non-protein nitrogen to protein was clearly demonstrable. This conversion, though small, was sufficient to account for the effective utilization of much more urea than would normally be included in the diet of the lactating cow.

The views expressed by Dr. Benesch on this subject, at least in so far as milk production is concerned, appear, therefore, to be fully supported by the present work. Moreover, it is pertinent to note that in the course of the investigation some of the excellent suggestions which he makes for future work have already been put into practice.

"Vegetables as Food"

IN a recent article in NATURE[1], it is stated that there is less carotene (provitamin A) in carrots than in spinach, watercress or broccoli. It would be dangerous to allow this statement to pass unchallenged. In reality, as was pointed out in a recent review in these columns[2], the carrot stands pre-eminent as a source of provitamin A. It is the only common foodstuff in Great Britain continuously available throughout the year, a single daily helping of which will supply the full requirement for vitamin A. It is unfortunate, therefore, that doubt should have been cast on this unique virtue of the carrot.

We have made many estimations in this Laboratory and rarely find a carrot having less than 18,000 I.U. per 100 gm. The usual value is more than 20,000, and values up to 38,000 have been obtained. Several varieties have been tested, the sizes varying from 10 to 1,250 gm. While leafy vegetables may be much superior to the carrot in respect of iron and water-soluble vitamins, few of them approach it in carotene content. For example, we find watercress has 2,500–5,000 I.U. per 100 gm., Brussels sprouts 200–600; common cress 1,500.

A possible explanation of the low value given by Dr. Pyke for carrots is that it has been taken from the published comprehensive Tables of Vitamin Values. Considerable discrimination is needed in the use of these compilations. Some of the entries for a given food are of little value compared with others, either because they are based on less accurate work, or because they represent single values rather than ranges of variations. Sometimes differences between species and varieties or the effects of other variables (for example, season, degree of ripeness, etc.) are overlooked. In the determinations on carrots we find that low results are obtained unless precautions are taken to ensure complete extraction and to avoid destruction of the carotene. The range of values for carrot given in Fixsen and Roscoe's tables[3], namely, 3,300–22,000 I.U. per 100 g., places the maximum where in our experience the mean should be. Unfortunately this range, or a mean obtained from it, is copied into other tables and books. The only common green vegetable quoted in these tables which even approaches these values is spinach (4,400–11,000).

We feel also that Dr. Pyke exaggerates when he makes an allusion, divorced from its context, to cooked cabbage as having only 17 per cent of the vitamin C of the fresh cabbage. Workers who have had most experience on the effects of cooking and processing would agree that under average household conditions a more usual loss would be of the order of about 40–50 per cent. With improved methods of cooking (such as boiling in a minimum of water for a minimum time, or by modified casserole cooking), the loss may be so low as 20 per cent.

IN NATURE of April 26 a comprehensive report is given of the meeting of the Nutrition Panel of the Society of Chemical Industry on "Vegetables as Food".

It is unfortunate that some of the facts on vitamin C given in our individual papers have been, in our opinion, misrepresented in this report, so that a false impression is given of the antiscorbutic value of cooked and canned vegetables. Some form of heat treatment is essential for the palatability of most vegetables. It is true that during such treatment a loss of vitamin C occurs, but to refer to "the devastating effect of cooking on the vitamin C in vegetables" and "the loss of the bulk of vitamin C" in the blanching process of canning, is to strain this fact out of its true perspective.

As we emphasized in our communications at the meeting, cooked and canned vegetables have, during this winter, been the main source of vitamin C for the majority of people in Great Britain. In addition we showed that normal portions of such vegetables, if properly chosen and handled by the housewife, can adequately supply the full daily requirement of the vitamin.

We would emphasize these points in view of the economic importance of heated vegetables under existing conditions.

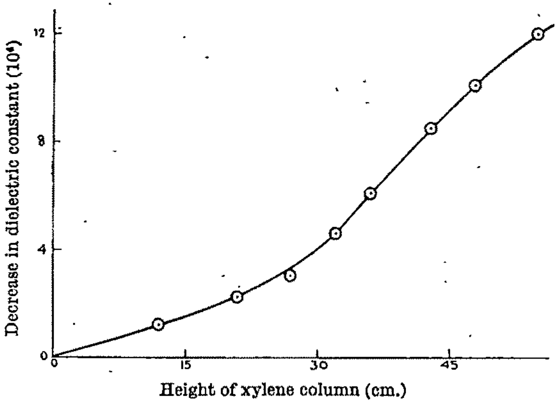
Effect of Flow on the Dielectric Constant of Liquids

We have observed that certain liquids, for example, xylene (a mixture of *ortho-*, *para-* and *meta-*), ethyl ether, ethyl alcohol and benzene show very small yet distinct decreases in the values of their dielectric constants when they are flowing through condenser plates of small separations. With a given separation the amount of change is found to increase with the rate of flow of the liquid. A typical graph showing the variations in the dielectric constant of a freshly distilled sample of xylene (a mixture of *ortho-*, *para-* and *meta-*) with flow under the pressure of different heights of the liquid is given in the accompanying graph. The temperature of the xylene remained practically constant at 24·0° C. throughout the experiment.

All the measurements for the dielectric constant were made by the usual heterodyne beat method using a wave-length of 300 metres. The experimental condenser consists of two horizontal circular brass plates; the lower one forms the main body of the apparatus, and the upper is separated from it by small, thin pieces of mica (thickness of the order of 0·01–0·02 cm.). The lower plate is provided with an opening at the centre which is connected by means of a U-tube to a long vertical glass tube of internal diameter 2·4 cm. The U-tube is fitted with a stopper. The upper plate is of diameter 8·6 cm. and of thickness 0·6 cm. and is fitted with a vertical rod at the centre. A load of about 10 kgm. is kept above the disk to prevent any mechanical displacement of the disk due to the hydrostatic pressure or flow of the liquids.

The condenser, the connecting tube and the vertical glass tube are filled with the liquid, and the flow of the latter commences as soon as the stopper is opened. The liquid rises through the central opening of the lower plate and after passing through the narrow space between the plates of the condenser comes out and is collected in a receiver. The level of the liquid in the vertical glass tube is kept constant by feeding the liquid at an adjusted rate from above. The changes in the capacity of the experimental condenser during flow are measured with the help of a specially designed condenser used by one of us[1] in the measurement of the dielectric constant of an electron atmosphere. With this condenser changes so small as 0·004 μμF. can be measured.

Precautions were taken to see that changes observed in the capacity during the flow of the liquid were not due to any spurious effect such as mechanical displacement of disk or similar stray capacity changes. The entire experimental arrangement is enclosed in a case lined with tin which is connected to the earth; all adjustments are made from outside.



Changes in the dielectric constant during flow are observed in polar as well as in non-polar liquids. But a more viscous liquid like amyl alcohol is found to show the effect to a much smaller degree. Observations with liquid heights greater than that shown in the graph could not be taken due to certain practical difficulties. Further investigations are, however, in progress and a detailed report will be published elsewhere.

We are grateful to Principal K. Prosad for the keen interest he has taken in this work.

Kinetic Friction Coefficient

The ordinary static friction apparatus with one mass m hanging over a pulley and connected to another mass M resting on the friction board may be used to determine the kinetic coefficient. Let m be more than sufficient just to move M, and let h be the vertical height over which m is allowed to accelerate M; then, if x is the extra distance along the board traversed by M before it is brought to rest by friction, the average coefficient is given by:

$$\mu_k = \frac{m}{M + \frac{(M+m)x}{h}}.$$

By varying m in order to get a range of speed, the following fairly consistent values were got:

M (gm.)	m (gm.)	Coefficient of kinetic friction
74·4	42·7	0·33
74·4	52·7	0·33
74·4	62·7	0·32
74·4	72·7	0·33
74·4	82·7	0·36
74·4	92·7	0·32
74·4	102·7	0·32
74·4	112·7	0·33
74·4	122·7	0·33

It may be that the method is in use, but a search in our selection of books on practical physics has not disclosed it.

RESEARCH ITEMS

Ptinid Beetles of Economic Importance

IN the *Bulletin of Entomological Research* (31, 331–381; 1941), H. E. Hinton, of the British Museum (Natural History), contributes a critical revision of 21 species of the family Ptinidæ that have been recorded as pests. The object of this work is to illustrate and describe these species in sufficient detail in order to facilitate their ready and accurate identification. In general, these beetles are known to infest an enormously wide range of stored products, and occur in houses, drug stores, warehouses and granaries. Some species have been found in association with such apparently unpromising substances as cayenne pepper, opium, argol and indiarubber. Others have been found in grain, nests of bees, in fish meal, cacao, in insect collections, birds' nests, etc. Three British species of Ptinus are of no economic importance, but have been included so as to make the paper applicable to all the British Ptinidæ. Six of the species of this family have not so far been found in Britain. It is interesting to note that several of the species have been known since the end of the eighteenth century, while *Ptinus fur* was described by Linnæus as *Cerambyx fur* in the "Systema Naturæ" (1758).

Chiasma Interference

H. B. NEWCOMBE (*Genetics*, 26, 128–137; 1941) has shown that coincidence values obtained from the direct observation of the position of chiasmata in *Trillium erectum* correspond with those of genetical analysis of cross-overs. Interference in an arm of a chromosome may still be present in a distance of 2 microns; above this distance the coincidence value does not differ from unity. Across the attachment constriction the value is significantly greater than unity. An increase in chiasma frequency is accompanied by decreased coincidence across the centromere and increased coincidence within an arm.

Inert Chromosomes

C. D. Darlington and M. B. Upcott (*J. Gen.*, 41, 275–297; 1941), have examined the behaviour of the *B* or supernumerary chromosomes of maize. These chromosomes are heterochromatic and have an excessive nucleic acid charge. Their chiasma frequency is less than proportionate to their length on the *A* chromosome standard. Since these *B* chromosomes may be reduplicated, it can be shown that the crossing-over frequency is increased with odd numbers of chromosomes; this is due to the potential increase in change of pairing partners. *B* chromosomes are irregular in behaviour during mitosis and meiosis and may be lost or give rise to chromosomes with deletions. On the other hand, lines of maize show a constant number of *B* chromosomes. Therefore, there would appear to be a selection pressure favouring *B* chromosomes. Thus the inert chromosomes would appear to be active in some physiological sense.

Sexuality in Wild Populations

THE occurrence of peculiar sex forms in species of plants has been a puzzle to many workers. In contrast to pure diœcism in higher animals, sex intergrades occur irregularly among plant species which are predominantly hermaphrodite. D. Lewis (*New Phyt.*, 40, 56; 1941) has shown that male-sterility of hermaphrodites due to cytoplasmic causes has more chance of survival than that due to genic male-sterility. With genic male sterility the frequency of 'females' in a population is 50 per cent and in no case can an equilibrium between 'females' and 'hermaphrodites' be reached unless the females are initially twice as fertile as hermaphrodites. On the other hand, cytoplasmic male-sterility can produce 100 per cent 'females'. If the 'females' have only a slight advantage over the hermaphrodites they will spread in the population. This advantage may be one of compulsory outbreeding, thus giving rise to hybrid offspring. Cytoplasmic sterility, therefore, is sensitive to several selective agencies in the wild population.

North Pacific Earthquake of November 10, 1938

AN important investigation is at present being made by K. E. Bullen and J. F. de Lisle on Rayleigh waves from the North Pacific earthquake of November 10, 1938. On account of the importance of this earthquake in the problem of Pacific crustal structure due to the unusually large and clear surface waves, J. F. de Lisle has estimated the degree of accuracy of the epicentre and origin-time used (Wellington, New Zealand: Dominion Observatory Bull. No. *S*-58; 1941). To do this a careful investigation was made of the *P* residuals, taking into account the ellipticity corrections. The author has shown by this work that the epicentre as assumed by the Jesuit Seismological Association, namely, 55·6° N., 157·7° W. is subject to an uncertainty probably not exceeding 0·3° in an east–west and 0·1° in a north–south direction, while the origin time of 20h. 18m. 48s. G.M.T. probably needs a correction of — 3 seconds.

A Closed Dyke-Sill Intrusion in the Transvaal

AN intrusion of altered quartz-dolerite of unique form, occurring in Marievale Mine and adjoining mines on the Far East Rand, is described by J. Ellis (*Trans. Geol. Soc. Africa*, 43, 127–142; 1941). The shape of the intrusion is that of a stepped dome of alternating dyke and sill phases. The intrusion, known in the mines as the 'Old Lady', never reached the surface, the top being of sill-like form below the Kimberley Shale. Against the inside of the dyke phases the strata are vertically displaced, the downthrow being equal to the thickness of the sill phase and generally of the order 150–200 ft. The dyke phases form closed rings at the levels where they occur, and there has been little or no horizontal separation of the strata. The mechanics of the intrusion are discussed in considerable detail. It is shown that the formations above the sill phases were not uplifted, but that subsidence of the rocks enclosed within the intrusion took place. The cause of subsidence, which cannot have been very deep-seated, is sought in the Basement Complex. It is suggested that the latter was weakened or melted by the rise of basic magma, and it is thought possible that the quartz-dolerite may be the result of contamination by granite of a parental basaltic magma. Evidence is presented that the age of the intrusion is just before or just after that of the Ventersdorp lavas which, petrochemically, are of similar type. Owing to the unusual shape, the reef displacement, and the toughness of the rock, the 'Old Lady' is everywhere a considerable source of embarrassment in mining operations.

Age of the Monchiquite Dykes of Colonsay

Two monchiquite dykes occurring in Colonsay belong to a suite of monchiquite and camptonite dykes, commonly following a north-west trend, of which members have been found in Coll, Iona, Mull and various parts of the mainland of Argyll. Although on grounds of petrographic analogy these are all thought to be of the same age, their geological relations nowhere provide direct evidence of what that age may be. The ages of the Colonsay examples have now been determined by the helium method by W. D. Urry, and for comparative purposes the ages of two Carboniferous basic rocks from Shropshire have also been measured. Petrological, chemical and other details of the rocks are provided by A. Holmes, who supplied the specimens, and the results are published in a joint paper (*Geol. Mag.*, 78, 45; 1941). Arising in part out of this investigation, it was found in 1937 that many of the helium ratios on which the 'helium' time-scale had been based were too high, because of a previously unsuspected error in radium determinations due to reliance having been placed on a radium standard which was seriously at fault. The new results, together with a few others, are given in the following table, which forms the nucleus of a revised 'helium' scale.

Geological age	*Rock type and locality*	*Age in millions of years, of the helium scale*
Pliocene	Basalt, Oregon (1)	8
Miocene	Basalts, Washington (3)	10
Oligocene	Basalts, Silesia (3)	20
Cretaceous–Jurassic	Granodiorites, California (5)	60
Triassic	Dolerites and basalts, New Jersey—Nova Scotia (8)	93–105
	Monchiquite, Colonsay (4)	125
	Biotite-monchiquite, Colonsay (4)	130
Upper Carboniferous	Dolerite, Clee Hills, Shropshire (1)	135
Lower Carboniferous	Basalt, Little Wenlock, Shropshire (1)	140
Devonian	'Newbury Volcanic Rock', Massachusetts (1)	180

The Colonsay results fall between those for the Triassic and the Carboniferous. It is therefore concluded that the Colonsay monchiquites are of late Carboniferous or Permian age, with considerable probability in favour of the latter. It should be noticed that although the 'helium' time-scale is internally consistent, the 'ages' therein are much lower than those given by the 'lead' method. The reason for this discrepancy is not yet known, and several investigators are collaborating in the attempt to elucidate it.

Variability of Rainfall in New Zealand

WHEN considering the suitability of a climate for most agricultural purposes it is necessary to know not only the average rainfall but also its variability. It is doubtless this fact which has led to the publication of *Meteorological Office Note* No. 24 of the Air Department, New Zealand, by C. J. Seelye, entitled "Variability of Annual Rainfall in New Zealand". Since the annual rainfall only is dealt with, the variability can be shown in a single map which brings out clearly the main features of its geographical distribution, variability being expressed by the average percentage variation from the mean for a selected period, in this case 1901–35. In New Zealand, low variability results when the fall comes largely from persistent westerly winds, while the rainfall derived mainly from easterly winds and from tropical cyclones shows high variability. For these reasons, areas with more than 18 per cent variability are found only in the north, and those with less than 8 per cent only in the extreme south, while the east on the whole is more variable than the west. The extremes are 8·7 at Queenstown and 21·2 at Petane, to the north of Napier. New Zealand is slightly less fortunate than the British Isles, where variability ranges from about 6 to 17 per cent only, with an average of roughly 11 per cent, but is far more fortunate than many countries bordering the tropics, for example, Arabia and Egypt, where variability exceeds 50 per cent. Nevertheless, in individual years single stations in New Zealand sometimes show departures from the average that must be very disturbing from the point of view of agriculture, the district including Nelson and Marlborough providing extremes of only 44 per cent in 1915 and as much as 232 per cent in 1936; in Southland, on the other hand, the corresponding extremes are only 63 (in 1907) and 153 per cent (in 1913).

Harmonic Analysis of Barometric Pressure

THE harmonic analysis of barometric pressure has been greatly extended geographically in recent years, and the latest addition comes from the Meteorological Office of New Zealand. In *Meteorological Office Note* No. 23 of the Air Department, New Zealand, C. J. Seelye discusses the variations at Wellington, New Zealand, for the period July 1914 to December 1938, during which time a Short and Mason barograph was in operation, at first at a height of 16 ft. above mean sea-level, but after September 1930 at a height of 425 ft. The indications of the barograph were corrected by means of mercurial barometer readings at 9 a.m. N.Z.M.T., supplemented after September 1930 by additional readings at 11.30 a.m. and 3 p.m. N.Z.M.T. Monthly values of the amplitude and phase angle for the 24-hr., 12-hr., 8-hr. and 6-hr. terms are discussed in detail. Of these, the second is, of course, the largest, the amplitude varying from 0·49 millibars in November (early summer) to 0·40 mb. in June. It is on an average for the whole year roughly three times as large as the amplitude of the 24-hr. term. The existence of one annual minimum value of the amplitude of the 12-hr. term had been noted at eight other stations in the southern hemisphere by Kochanski, who observed that the normal rule is for maxima to occur at the equinoxes and minima at the solstices. The 8-hr. term has very regular characteristics, although much smaller than the two already described; it reaches a maximum in January and July, and almost disappears in March and October. An item of practical importance in weather forecasting, which is included in this study of pressure variation, is a table showing the mean barometric 'tendency' (that is, change in tenths of a millibar in 3 hr.) for different hours of the day, a quantity which when subtracted from the observed tendency leaves the portion which may be attributed to the movement or development of anticyclones or depressions.

Distribution of Electricity in Thunderclouds

OBSERVATIONS made on thunderstorms at Kew Observatory during 1937–39 are reported in detail by Sir George Simpson and G. D. Robinson (*Proc. Roy. Soc.*, A, **177**, 281; 1941). In every thundercloud there is a positive charge of electricity near the top of the cloud, where the temperature is below – 10° C., and a negative charge below the upper positive charge. The generation and separation of these charges occurs in the ice region, and the most probable cause is the collision of ice crystals in the turbulent air associated with the strong ascending currents in a thunderstorm. The collisions charge the ice negatively and the air positively, and it is the settling of the ice crystals relatively to the air which separates the positive and negative charges. Below the main negative charge in the lower half of the cloud there are in most, if not in all, thunderstorm, regions containing positive charges. With few exceptions the temperature where these positive charges occur is above the freezing-point. These low positive charges are associated with heavy rain and they are probably generated by the breaking of raindrops in ascending currents of air.

Ferric Thiocyanate

THE blood-red colour formed from ferric salts and thiocyanates in solution, usually attributed to ferric thiocyanate $Fe(CNS)_3$ (which is soluble in ether) has been regarded by Schlesinger and Van Valkenburgh (*J. Amer. Chem. Soc.*, **53**, 1212; 1931) as due to a complex anion $Fe(CNS)_4'''$, and this view has found its way into the literature. H. E. Bent and C. L French (*J. Amer. Chem. Soc.*, **63**, 568; 1941) have made a new investigation of the matter by a method in which the dependence of the molecular extinction coefficient of the solution on the concentration of ferric and thiocyanate ions at constant *p*H and ionic strength is measured, and they find no evidence for the existence of an ion $Fe(CNS)_6'''$. The supposed migration of the coloured ion towards the anode could not be confirmed; there was only a slight movement towards the cathode. The conclusion is reached that the coloured substance is a cation, $FeCNS^{\cdot\cdot}$, but more work is obviously necessary before the old view that it is undissociated ferric thiocyanate is definitely rejected.

Electrical Properties of Solids

THE properties over a wide temperature range have been determined by R. M. Fuoss for a number of polar polymers, such as polyvinyl chloride, subjected to alternating current at 60–10,000 cycles (*J. Amer. Chem. Soc.*, **63**, 369, 378, 385; 1941), the work extending also to mixtures. Characteristic maxima in absorption and dispersion in dielectric constant were found which are interpreted as determined by the size and strength of the polar group, by the length and flexibility of the bond of the polar group to the polymer chain, and by the nature and amount of a second component present as a plasticizer. The fundamental mechanism of alternating field response, it is concluded, is dipole rotation in a medium of high viscosity, the primary effect of temperature being to change this internal viscosity. A transition temperature is described as relating to a process of internal melting. For mixtures, the loss factor for a given frequency and temperature passes through a maximum at a concentration which is characteristic of a given plasticizer. The electrical properties are markedly non-linear in composition in the low concentration range. A method of calculating the distribution of relaxation times from the loss factor — frequency curve is given, and for systems containing polyvinyl chloride an approximate equation is given for these curves. The C–Cl moment in polyvinyl chloride is calculated as 2·0. The theory is in agreement with previous empirical conclusions concerning chain interaction in polymeric systems.

Molecular Anisotropy of Urea and Related Compounds

A CONSIDERABLE amount of data on the magnetic and optical properties of urea and related substances has been correlated in a paper by K. Lonsdale (*Proc. Roy. Soc.*, A, **177**, 272; 1941). From comparisons of the magnetic anisotropy of urea with that of the carbonate and nitrate groups it appears that the hydrogen bonds contribute little to the anisotropy. The anisotropy of the refractivities is greater in urea than in the carbonate group. Urea nitrate, urea oxalate, cyanuric acid dihydrate and anhydrous cyanuric acid all crystallize in larger structures, as shown by cleavage, X-ray, magnetic and optical data. Although the molecules in each layer are joined together by hydrogen bonds, the links between successive layers may not be hydrogen bonds since the layer to layer distance of 3·05 ± 0·10 A. is characteristic even of cyanuric triazide, which contains no hydrogen bonds.

Comet Cunningham, 1940 *c*.

IT is reported from the McDonald Observatory, Texas (*Harvard Announcement Card*, **556**; Jan. 8, 1941) that spectrograms of Comet Cunningham show near 3360 and 3090 A. two prominent groups of lines not hitherto observed in cometary spectra. The first group consists of seven lines of the (0, 0) and (1, 1) bands of the $^3\Pi \rightarrow {}^3\Sigma$ system of NH. The second, also comprising seven sharp lines, arises from the (0, 0) transition of the $^2\Sigma \rightarrow {}^2\Pi$ system of OH. Other ultra-violet lines on the same spectrograms are attributed, though with less certainty, to CH and CN. The identification of NH and OH adds two more molecules to the five previously recognized in comets: CN, C_2, CH, CO^+ and N_2^+. As with these latter, the observed lines of the newly discovered molecules arise from resonance transitions, and the current theory of resonance excitation is adequate to account for their presence. In the visual region, the *D* lines of sodium appeared faintly in emission at the end of December and strengthened rapidly in early January. This, too, is to be expected since the comet made its closest approach to the sun in mid-January. A series of excellent direct photographs of the comet appearing in the *Telescope* of Jan.–Feb., 1941, traces its development from discovery in September 1940 to the end of the year.

DEFICIENCY OF WHITE FLOUR IN RIBOFLAVIN

(Tested with the Flour Beetle *Tribolium confusum*)

By Dr. G. Fraenkel and M. Blewett,

Department of Zoology and Applied Entomology, Imperial College, London

THE experiments described here were suggested by the decision of the Ministry of Food to "fortify" white flour by the addition of vitamin B_1 and salts, and by the criticism raised against this proposal (for example, Chick 1940[1], Willcox 1941[2]).

It is to-day general knowledge that highly milled white flour, as compared with wholemeal flour, is deficient in vitamins of the B group and salts and also contains less fat-soluble substances and protein. To use an insect as test animal for vitamins is no novelty, although this method has hitherto been little used. The flour beetle, *Tribolium confusum*, particularly has several times proved to be a very satisfactory test animal owing to its small size, its short life-cycle and its ability to grow normally on substances with a water content of only 10–15 per cent[3-8]. In testing for nutritional deficiencies in flour it is a particularly favourable experimental subject, since flour is its natural food and no other food is required.

If the environmental factors of humidity and temperature are kept constant and at a favourable level, for example, in the experiments described here at 25° C. and 70 per cent humidity (corresponding to a water content of about 14 per cent), the speed of growth is optimal on wholemeal flour and the mortality is almost nil. On interfering with the composition of the food any nutritional deficiency expresses itself in retardation of growth and sometimes also in increased mortality. As the growing period is finished with the formation of the pupa the duration of the larval stage from the hatching of the larva from the egg until pupation constitutes the most significant figure for comparing the efficiencies of different diets.

Long ago it was pointed out that growth of Tribolium is much retarded on white flour. This is shown in the graphs of Fig. 1. On wholemeal flour pupation takes place after 25–28 days, and on a sample of highly milled patent flour (Burtonsbest, extraction about 40 per cent) 32–48 days. National straight run flour (extraction 73 per cent), the highest extraction permitted during the War for baking of white bread, on which pupation takes place after 29–32 days, shows a great improvement over patent flour, but is still markedly and significantly behind wholemeal flour in nutritional qualities. Addition of wheat germ to patent flour in increasing quantities results in the developmental period being progressively shortened until, with 2–4 per cent germ present in patent flour, its efficiency is about the same as that of wholemeal flour. In the wheat grain the germ constitutes about 2 per cent. Admixture of yeast (dried brewer's) to patent flour produces an even slightly more favourable effect than admixture of wheat germ. It therefore appears that if the external conditions are kept sufficiently constant small amounts of wheat germ admixed into a sample of highly milled flour can be assessed with a fair degree of accuracy by feeding the flour to Tribolium.

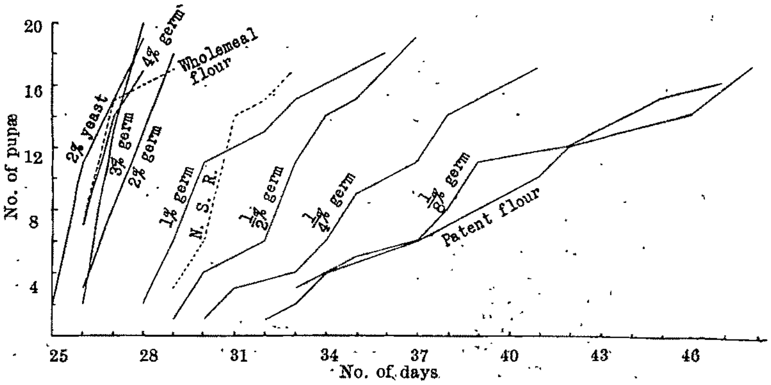

Fig. 1.

Larval growth of *Tribolium confusum* on wholemeal flour, National straight run flour (N.S.R.), patent flour and on patent flour supplemented by varying amounts of wheat germ or by yeast.

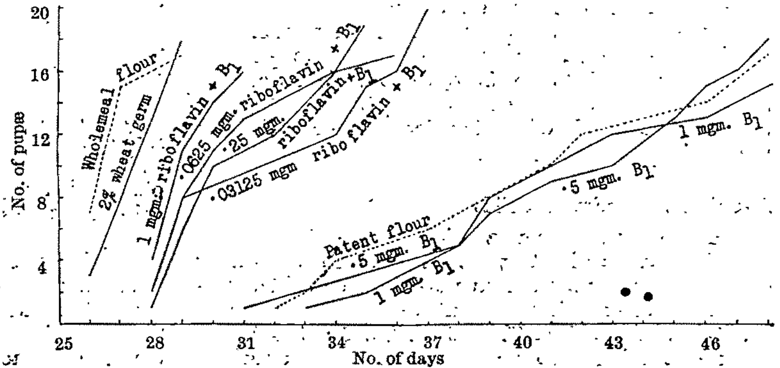

Fig. 2.

Larval growth of *Tribolium confusum* on patent flour supplemented by vitamin B_1 and riboflavin. Quantities per 2 gm. of food.

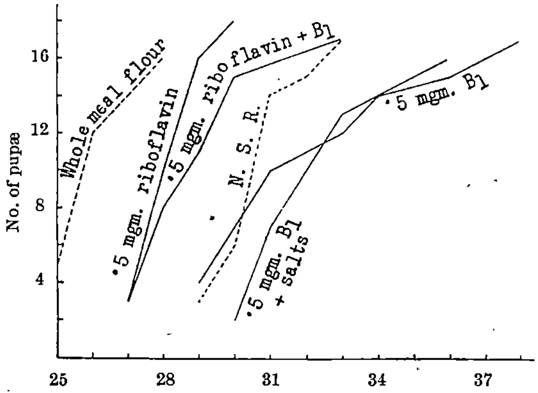

Fig. 3.

LARVAL GROWTH OF *Tribolium confusum* ON NATIONAL STRAIGHT RUN FLOUR (N.S.R.) AND ON N.S.R. SUPPLEMENTED BY VITAMIN B_1, RIBOFLAVIN AND SALTS. QUANTITIES PER 2 GM. OF FOOD.

Addition of pure vitamin B_1 (aneurin) to patent flour does not in the least alter its nutritional qualities ; addition of riboflavin, however, to patent flour containing vitamin B_1 causes a very startling improvement (Fig. 2). We have found that very small quantities of riboflavin produce a marked effect (0·031 mgm. per 2 gm. of food). (Fröbrich (1939)[7] has shown Tribolium to grow well on food containing only 0·008 mgm. of riboflavin in 1·5 gm. of food. Larger quantities were found to be toxic, but we cannot confirm this.) The apparent differences in the efficiency of diets containing different quantities of riboflavin are possibly not significant and may be due to insufficient mixing. Riboflavin was mixed with patent flour in the dry state, and the series was obtained by dilution with more patent flour. It appears, therefore, that most of the deficiency of patent flour is remedied by addition of riboflavin. In this dilution series with riboflavin the diets also contained vitamin B_1 (0·5 mgm. per 2 gm. of food). Later experiments proved, however, that the same favourable effect is produced without adding B_1.

Similar experiments with National straight run flour (N.S.R.) led to the same kind of results (Fig. 3). Although the nutritional qualities of N.S.R. for Tribolium are not much inferior to those of wholemeal flour, addition of riboflavin to N.S.R. produced a marked improvement. Adding B_1 to N.S.R. alone or to N.S.R. plus riboflavin caused the diets to be slightly less efficient, which, however, might not be significant.

An attempt was also made to find out whether any deficiency of salts in patent flour and N.S.R. could be demonstrated. Addition of MacCollum's salt mixture in the proportion of 1 per cent to patent flour and to N.S.R., however, showed no significant effect (Fig. 3).

The results obtained with Tribolium fully agree with those recently reported by H. Chick[1] on the white rat. In both cases the nutritive value of N.S.R., even when supplemented with vitamin B_1 and salts, is markedly inferior to that of wholemeal flour. Chick's suggestion that this may be partly due to deficiency in riboflavin has been proved to be correct. Most of this deficiency is corrected by adding riboflavin. Moreover, the efficiency of patent flour and N.S.R. both supplemented with riboflavin is almost identical, and the efficiency of supplemented patent flour is apparently greater than that of unsupplemented N.S.R. (Figs. 2 and 3). This proves that the nutritional difference, demonstrable with Tribolium, between the two kinds of white flour of 40 and 73 per cent extraction is almost entirely due to lack of riboflavin in patent flour.

No practical conclusion can be drawn from the fact that Tribolium does not need more B_1 than is present in patent flour. Since the deficiency of white flour in B_1 is well known and the need of Tribolium for B_1 has been demonstrated, the amount of B_1 in patent flour seems to be well above the threshold of the requirements of Tribolium. On the other hand, if one considers the very low requirements of Tribolium for riboflavin and the startling improvement in the nutritional qualities of white flour after adding riboflavin, the deficiency of patent flour and even straight run flour in riboflavin must be regarded as being serious. Supplementing white flour with vitamin B_1 would, therefore, leave the deficiency in riboflavin unremedied.

We wish to thank Dr. J. D. Mountfield, of the Research Association of British Flour Millers, for supplying samples of National straight run flour, patent flour and wheat germ.

FATIGUE FOLLOWING HIGHLY SKILLED WORK*

BY PROF. F. C. BARTLETT, F.R.S.

IF the character and causation of fatigue following highly skilled work are to be understood, the first need is for the discovery of more relevant and experimentally controlled facts. Unfortunately, almost all the investigators who have attempted to study fatigue of this type have adopted methods taken over with very slight change from those which have proved valuable in the study of simple muscular fatigue. They have chosen elementary operations usually considered to require some 'mental' effort—such as easy calculations, word or colour recognition and naming and the like—have repeated these operations over and over again for long periods, and have tried to express the resulting fatigue in terms of the diminution in quantity or quality of the work done.[1]

The skill fatigue of daily life is not set up under such conditions. Routine repetition of simple actions

* Substance of the Ferrier Lecture of the Royal Society, delivered on May 29.

is not characteristic of any highly skilled work, and least of all of work having a strong 'mental' component. The operations involved here are marked by complex, co-ordinated and accurately *timed* activities. The stimuli in response to which these activities are set up are neither simple nor do they usually fall into an order of fixed succession. They have the character of a field, or a pattern, which has become very highly organized, and may retain its identity in spite of a great diversity of internal arrangement.

It is possible to develop fully controlled experimental situations in which these realistic considerations have full play. When this is done, the picture of fatigue following highly skilled work which emerges has certain strongly marked characters.

In such fatigue the 'standards' accepted and followed by the central nervous system unwittingly deteriorate. The operator tends to think that he is doing better work, because errors treated as significant all the time get wider and wider limits. Until a stage of great fatigue is reached, it is far more likely that the right actions will be performed at the wrong times than that the wrong actions will be performed. If accurate timing is insisted upon, gross mistakes of action may appear. The stimulus field splits up. Its pattern character alters. It becomes a collection of unconnected signals for action, with some of these predominant over all the others. Particularly stimuli which are in the margin of the pattern, not closely organized with the central field, are ignored, 'forgotten', and serious lapses of specific reactions occur. There is a marked change in the effect of certain 'distracting', or additional stimuli. Sensations of bodily origin, in particular, become more pressing and insistent, and affect the performance in ways peculiar to the tired operator.

Side by side with all these changes go constant subjective symptoms. Verbal reports about any circumstances connected with known failure of performance become increasingly inaccurate, and errors are regularly projected upon objective conditions, or attributed to the interference of other people. There is a tremendous growth of irritability.

The light thrown by this picture upon the relation of high-level central nervous functions to simpler neuro-muscular mechanisms was discussed.

ROLE OF RADIATION MUTATIONS IN MANKIND*

By Dr. H. J. Muller

ACCEPTING, on the basis of work with organisms in general, including mice, the conclusion that X-rays and other high-energy radiations produce gene mutations in any human germ cells that are exposed to them, with a frequency exactly proportional to the dose of radiation used, we may ask: What are the conditions governing the manifestation of these mutations? When attention is confined to the recessive gene-mutations, which appear as the most pronounced and constant, yet insidious, genetic effects, it may be approximately calculated how long the latent period would be between the time of exposure of an individual who afterwards reproduces and the appearance of some descendant manifesting a recessive mutation that had been produced in one of the former's germ cells.

For the manifestation of a recessive gene two germ cells having the same allelically acting recessive genes must come together, forming a homozygote—an event that would happen with almost negligible frequency in the first-generation offspring, even from two irradiated parents. There are, however, two ways in which a homozygote manifesting the mutated gene could eventually be formed. One is by a germ cell containing it meeting in fertilization another germ cell which chances to contain an identical or allelic recessive gene which, having originated by some independent mutation, was already present in the population in some parallel line of descent. The chance of this event depends upon the frequency of such recessive mutated genes in the general population, and this can be calculated if we know the so-called 'spontaneous' mutation frequency, the rate at which individuals manifesting such genes are being eliminated in competition with normals, and the amount of inbreeding in the population. Sufficient data exist for calculating that under the condition of random breeding—which would give the highest frequency of such genes—very few recessive genes the manifestation of which would be of seriously detrimental character would exist in frequencies exceeding 1 in 30 or, more probably, 100 germ cells, in the general population. Thus it would on the average require some 30 or, more likely, 100 or more generations of breeding—some 750–3,000 years of human history—before the mutated gene would manifest itself by this process.

The other way in which the gene could manifest itself would be by a germ cell containing it meeting another containing a relative, so to speak, of the same gene, that is, an identical gene derived from the same ancestral mutated gene of the original treated individual. This requires the breeding together of more or less related individuals—'inbreeding'—and the chance of its occurrence depends on the total amount of inbreeding occurring in the population. In determining the frequency of this effect a special method of calculation has been employed, utilizing a simple proportionate relation of 1 to 4 which I have calculated to hold between the frequency of two related genes thus meeting each other and the frequency of two individuals having the same name by reason of some near or distant relationship marrying each other. Reckoning from known statistics on the latter events, it can be shown that, even in rural English communities, the chance of a mutated gene manifesting itself by this process is only about 1 in 200. That is, it would on the average take about 200 generations, or at least 5,000 years, for the gene to attain manifestation in such manner. Both causes operating together would not suffice to give a period of less than 600 years, and more probably one of thousands of years.

Of course these periods are only averages for the time of first manifestation; actually, the first manifestations of the different mutated genes would be scattered rather evenly over the entire time from the generation after treatment until two or three times the length of the 'latent period' had elapsed It is to be noted, further, that this protracted 'latent period' does not mean that the mutated genes would tend, collectively, to become lost in the interim, since for each gene that died out by accident, in its 'covered' state, another would, on the average, increase in numbers, and so the final number of individuals first manifesting the mutations would fairly accurately represent the number of individuals produced in the first generation after treatment who had received the newly mutated genes. That is, the damage would be long postponed, but not prevented.

---

* Substance of a paper read at the annual meeting during April 28–29 of the U.S. National Academy of Sciences.

In so far as the individuals manifesting the abnormalities might themselves reproduce they would give them a chance to reappear repeatedly, until competition with the normals finally eliminated them. The recognition of these abnormals as having been produced by the original treatment would, however, be impossible, not only because of the long latent period but because they would appear merely as one relatively small part of the vast number of mutations that had occurred in the distant past, from all causes combined, and that had accumulated in the germ plasm. It can be shown that even if the mutation frequency of the population as a whole were doubled, in a given generation, by treatment of all of them with an average dose of, say, 300 r. the frequency of mutations that *manifested themselves* in the population would not be increased, in any one generation, by as much as 1 per cent of their own total, since the manifestation of the new additions to the store of mutations would be scattered over so many generations. If, however, the exposure that doubled the mutation frequency were to be continued generation after generation, the manifestation frequency would gradually rise and finally (after some hundred generations) attain the double value representing the double mutation frequency.

In these circumstances, the advisability of allowing the gonads of a person of reproductive or pre-reproductive age to be exposed to radiation must be decided by balancing the chance of benefit to him against the chance of detriment to future generations. Far more quantitative research is needed on this matter, but it will often be clear that the decision should be in favour of the exposure. Whenever possible, however, a person's gonads should be protected by a lead shield.

As for the question of the mutational effects of natural radiation, while this has been calculated to be of no consequence in flies, the 700-fold greater length of the human generation gives a chance for the accumulation of a sufficient dosage—some 10–15 r. —to have an appreciable effect in view of its also being continued generation after generation. More exact studies are therefore called for concerning the circumstances attending exposure of populations to unusually high amounts of such radiation, as well as of radiation of artificial origin.

SKIN EFFECT IN COMPOSITE AND FERRO-MAGNETIC WIRES

THE British Electrical and Allied Industries Research Association has published a report by G. G. Sutton on the high-frequency properties of wire specimens*. Novel results have been found in connexion with the effect of a longitudinal magnetic field on wires made of magnetic material. Ferromagnetic wires are shown to have very high 'skin' factors, but the effective permeability determined from the experimental results is shown not to be constant but decreases to a small value as the frequency increases.

Earlier mathematical calculations have assumed a uniform known permeability, but it is known that with ferro-magnetic conductors the permeability varies with the magnetizing force, and hence it must vary over the cross-section of the conductor. It also varies with the current density and the temperature. In addition, hysteresis losses must be considered. Accordingly a mathematical solution is intrinsically very difficult, and it therefore seems necessary to have some direct means of measuring skin factor for magnetic and composite conductors.

The author describes two methods of doing this, both methods being based on thermal measurements. The first apparatus consists of two parallel brass tubes inside which were the specimen wire and a standard wire of eureka respectively. The heating effect of the current in the two wires was measured by observing the extensions by means of a travelling microscope. Both the eureka and iron wires were calibrated with direct current. A simple mathematical relation is then deduced to give the required skin factor. A more accurate method was afterwards developed, mercury being used at first as the indicating fluid, but it was abandoned as it was not sensitive enough. Finally, the liquid decided on was nitrobenzene as its physical properties were found most satisfactory.

The method of measurement developed for skin-factor measurements is shown to give consistent results with different types of specimen. The calculation of results in the case of ferro-magnetic materials is difficult, and in the case of composite materials it is very difficult. The author's method of measurement is direct and calculation is much simplified.

The method can be easily applied to the measurement of high-frequency currents. By further development it would be possible to eliminate many of the difficulties met with in this research. The effect of a longitudinal direct-current field on the high-frequency resistance of a mumetal specimen has been demonstrated ; this is in accord with results already published on the arc impedance of specimens of mumetal wire at telephonic frequencies. From the results obtained in the case of ferro-magnetic materials, the effective permeability has been calculated ; this tends to a small value as the frequency increases, as indicated by Arkadiew and others. Constructional diagrams are given for making the apparatus, and experimental diagrams are given showing the variation of skin factor with applied D.C. field in the case of a specimen of 26 S.W.G. mumetal wire.

FORTHCOMING EVENTS

Monday, June 9

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 5 p.m.—Squadron-Leader P. J. A. Riddell: "Air Photography in War".

Tuesday, June 10

CHEMICAL ENGINEERING GROUP (SOCIETY OF CHEMICAL INDUSTRY) in conjunction with the INSTITUTION OF CHEMICAL ENGINEERS (Joint Meeting at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. G. H. Miles: "The Human Factor in Chemical Engineering Processes".

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 2.30 p.m.—Miss Audrey I. Richards: "Some Causes of a Revival of Tribalism in South African Native Reserves".

Wednesday, June 11

INSTITUTION OF GAS ENGINEERS (at the Institution of Mechanical Engineers, Storey's Gate, London, S.W.1), at 10 a.m.—78th Annual General Meeting; at 10.30 a.m.—Mr. George Dixon: Presidential Address.

ROYAL SOCIETY OF ARTS (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 2.30 p.m.—Mr. F. C. R. Douglas: "Economic Aspects of Soil Fertility and Nutrition".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

BOROUGH EDUCATION OFFICER—The Secretary, Education Offices, Stoke Road, Gosport, Hants. (June 10).

FARM SURVEY SUPERVISORY OFFICER, an ASSISTANT ADVISORY CHEMIST, a FIELD ASSISTANT (AGRICULTURAL CHEMISTRY), and a PERMANENT TECHNICAL ASSISTANT (AGRICULTURAL ECONOMICS)—The Registrar, The University, Manchester 13 (June 11).

HEAD OF THE COMMERCIAL DEPARTMENT—The Principal, Technical College, Park Square, Luton (June 14).

PROFESSOR OF ZOOLOGY—The Secretary, The University, Edmund Street, Birmingham 1 (June 16).

ASSISTANT ENGINEER to the Middle Level Commissioners for Land Drainage Works—The Engineer, Middle Level Offices, March, Cambs. (June 16).

HEADMASTER—The Clerk to the Governors, Dulwich College, Dulwich, London, S.E.21 (June 21).

HEAD OF THE MECHANICAL ENGINEERING DEPARTMENT of the Salford Royal Technical College—The Director of Education, Education Office, Chapel Street, Salford 3, Lancs. (June 21).

SECRETARY OF THE WESTERN DISTRICT OF THE WORKERS' EDUCATIONAL ASSOCIATION—The Acting District Secretary, 9 Ashley Park, St. Andrew's, Bristol 6 (June 28).

ASSISTANT TO THE ENGINEER-IN-CHIEF—The General Manager and Secretary, Mersey Docks and Harbour Board, Dock Office, Liverpool (June 30).

HEADMASTER of the High School for Boys—The Secretary, King Edward's School, Edgbaston Park Road, Birmingham 15 (July 5)

HEADMISTRESS of the High School for Girls—The Secretary, King Edward's School, Edgbaston Park Road, Birmingham 15 (July 5).

TRAVELLING INSPECTORS OF DRYING PLANT for the Dehydration Branch of the Emergency Services Division of the Ministry of Food—Ministry of Labour and National Service, Central Register (Z.184), Queen Anne's Chambers, Westminster, London, S.W.1.

ASSISTANT IN THE MECHANICAL ENGINEERING DEPARTMENT—The Principal, Technical College, Wolverton, Bucks.

ELECTRICAL ENGINEER for the Public Works Department of the Nigerian Government—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1 (quoting M/9422).

WARDEN—The Principal, Domestic Science College, Knighton Fields, Leicester.

WOMAN LECTURER TO ASSIST IN BIOLOGY AND GEOGRAPHY—The Principal, Edge Hill Training College, Bingley, Yorks.

ORGANIZATION OF CIVIL DEFENCE

THE Government decision to transfer the fire-fighting organizations from the control of local authorities, and to re-group and reinforce them under the general control of the Ministry of Home Security, thus establishing a national fire-fighting service, has been generally welcomed. The debates in the House of Commons indicate that the Reorganization of the Fire Services Act gives expression to a principle which is regarded as essential by all who have had first-hand experience of heavy air raids and which has already found firm advocacy in various reports and inquiries, from the P E P Broadsheet "London under Bombing" to the recent fourteenth report of the Select Committee on National Expenditure.

Inevitably the whole question of civil defence administration is raised by a change of this magnitude, and the report of the Select Committee makes an important and opportune contribution to such discussion. The decision to base the administration of the fire services on the twelve Civil Defence Regions and as many sub-regions as efficiency requires involves important detailed reforms—the separation of the administrative from the executive side of fire-fighting, the appointment of recognized and recognizable chiefs to whom reinforcements can report on arrival in a heavily bombed area, and the strengthening of the fire-fighting army by the allocation to it of some of the men called up under the National Service Act. From such reforms it should be a simple matter to use regional authority to implement the main recommendations of the Select Committee in this field.

The more important of these recommendations are clearly matters in which regional authority can best help. A systematic attempt to ensure that all brigades should be given experience of fire-fighting under air-raid conditions; the revision of the fire-fighting orders and the securing that fire-fighting parties are really efficient; the standardization of hours of duty of firemen and improvement of accommodation; the development of the Supplementary Fire Party Service and its relation to the strength of the Auxiliary Fire Service, and measures to improve water supplies, are all matters in which local authority or experience alone has been and is inadequate.

While it remains to be seen whether the Ministry of Home Security and the Regional Commissioners in different circumstances will receive the complete planning and the scale of equipment and personnel which will be adequate to bring sufficient forces to bear in time anywhere and everywhere the enemy may attack, it is significant that the Select Committee goes beyond the Government's present plans in contemplating no divorce between fire-fighting and fire-prevention. The trend of the report suggests that it is unlikely to countenance as adequate the immediate step of placing Miss Wilkinson, the efficient Additional Parliamentary Under-Secretary to the Ministry of Home Security, in charge of the training and equipment of the fire-fighting and fire-watching groups. It scarcely appears to give such parties the status, training and discipline of other Civil Defence Services as recommended in the Report, or to provide the nucleus of paid whole-time workers regarded as essential.

The importance of staff work in this field has not yet been fully appreciated, nor the two functions—that of the general staff officer and that of the officer in the line—clearly recognized. The chiefs of the various fire regions must be selected primarily for their administrative ability, while the Select Committee points to the necessity of also staffing key positions in constantly raided areas which involve continuous administrative duties with full-time workers chosen for such ability. Thorough training of the fire watchers and bringing this service to its full efficiency by the wise use of compulsory powers and establishment of close relations with the other fire services has an important bearing on the strength of the Auxiliary Fire Service.

While it is now recognized as beyond question that in any field of civil defence planning within the administrative boundaries of individual local authorities is disastrous to efficiency, the Select Committee does not consider that this alone is sufficient. Regional authority may be adequate to move unhesitatingly where required more than one third of a force from an area and to see that such reinforcements are adequately directed both *en route* and in action. Something more than regional authority is required, however, if the most efficient balance between whole-time and part-time personnel is to be secured.

Such matters as these involve the general question of man-power policy and the use of the powers of the Defence Regulations or relations with other Government Departments, and for these reasons the Report recommends further consideration of the concentration of all civil defence functions in a single Ministry. In particular the administration of all the civil defence functions of the Ministry of Health should be delegated to regional commissioners. Some of the shortcomings have been due to fundamental weaknesses in the administrative machine, such as lack of control by the central department. While the regional organization has avoided delay in reaching local decision, it has frequently failed to preserve control of policy. Its co-ordinating functions, particularly at the level of the central departments, through failure to see the problems of civil defence as a whole, have been seriously hampered by the division of responsibility between the Ministry of Home Security and the Ministry of Health or the Department of Health for Scotland, and the difference in the extent of departmental devolution for different services.

Co-ordination of the various Civil Defence Services and also economy, by avoiding duplication of inspectorial and administrative staffs, would be facilitated by the delegation to the Regional Commissioners of the administration of all the civil defence functions of the Ministry of Health and of the Department of Health for Scotland (with only such limitations as necessarily apply to the hospital services and evacuation). If, however, civil defence could be organized *de novo* it would undoubtedly be placed under a single Minister unburdened with other responsibilities, and the wisdom of this solution is well attested by the detailed recommendations of the Report, which so often reiterate proposals advanced elsewhere by Political and Economic Planning and other bodies. Moreover, strong support for the appointment of a single Minister of Civil Defence has been forthcoming from other quarters as indicated by press correspondence and articles.

There is, moreover, a further aspect of this question of Ministerial co-ordination which may be of importance in post-war developments of regionalism. Despite the impetus which the War has given to regionalism by revealing the weaknesses and limitations of local government, there does not appear to be any hostility on the part of the local authorities to regionalism. On the contrary, generally speaking, a happy co-operation has been established between the regional commissioners and the local authorities, and machinery at both ends has been improved and adjusted to meet constantly changing problems. Regional commissioners have rarely found it necessary to exercise their powers of superseding an inefficient local authority in its civil defence functions. Local authorities, however, were not designed to deal with the conduct of what the Home Secretary has described as a "military operation" on a large scale, and the closest co-operation between them can be no substitute for either regional or national control.

While, therefore, we may well hope that the stimulus to regionalism in civil defence or in other fields given by the War may prove invaluable in educating local authorities and public opinion as to the value of a regional approach to numerous other problems such as water or power supply, transport, land utilization, and the like after the War, it should not be forgotten that in a democracy regionalism is itself an instrument developed to meet particular conditions, and that it must satisfy the democratic conditions of flexibility and responsibility. It may well be necessary to extend the powers of the regional commissioners as part of the administrative machinery of military defence, for which local government cannot be expected to be suitable, and to make those powers more concrete in respect, for example, of food, evacuation and transport. If that is done, however, the question of public responsibility of the Commissioners becomes the more important under any democratic system.

To place the Commissioners under a single Ministry responsible to Parliament should go far to facilitate co-ordination and central control of policy and to meet the criticism of responsibility which has sometimes been advanced. Such a step might well ensure the fullest efficiency and dispel the uneasiness which may attach even in war-time to the entrusting of such wide powers to single individuals, in contrast to regional organizations, divorced from local responsibility in fields which have hitherto been administered largely from that point of view. We cannot afford even in war-time to overlook the importance for developing a democratic system, adequate to meet post-war demands, of continuously educating public opinion as to the issues involved and of digging the channels of assent to future changes or developments.

Apart from this broad question of administration, the Select Committee's report emphasizes the way in which the question of civil defence is linked up with the most efficient use of our man-power and woman-power. Its proposals for reducing the requirements of man-power for the Civil Defence Services are based on the experience which has now been gained of heavy raids, notably the outstanding fact that the loss of life and injury to persons has been much less than was expected, while material damage has been greater. Generally speaking, the Fire and Rescue Services have proved no more than adequate and in a few places actually deficient. Casualty services, on the other hand, have generally proved ample to meet the demands made upon them, and the Committee accordingly has been able to recommend reductions in the strength of these services.

Its main general recommendation for reducing the requirements of Civil Defence for man-power is the recruitment of part-time unpaid workers. Whole-time personnel should only be resorted to when part-time personnel cannot be obtained by voluntary recruitment or by compulsory enrolment under Defence Regulation 26A. In particular, the air-raid wardens' service should substantially revert to its original part-time basis and the paid element, so far as possible, be eliminated. Increase of the part-time element in the Report and Control Centres by encouraging the recruitment of business men and officials is also recommended, as well as consideration of the possibility of strengthening the Rescue Service by enlisting the building trades as a whole in an area for part-time service at normal rates of wages.

Other suggestions for saving man-power include the reduction of day-manning strengths to the minimum consistent with safety; the establishment of mobile reserves of rescue parties; the intensive review of operating methods and the review and reduction of the number of ambulances and first-aid posts in the light of present experience. Severe criticism is passed on the Emergency Hospital Scheme for the absence of information which would enable any judgment to be reached as to whether nursing staffs are excessive, and the interchange of nursing staff between standing-by and hard-pressed hospitals is recommended.

Other severe criticism is passed on the shelter policy, the absence of standards, and the giving to the regional commissioners of a discretion amounting to control of policy. The amount of shelter, public and domestic, to be provided in less vulnerable areas should be clearly laid down according to a standard, and the places where shelter is to be provided should be determined on a definite classification of areas according to vulnerability. The administrative responsibility for the provision of all kinds of industrial shelter should be placed upon the regional commissioner and his technical staff.

These recommendations alone indicate how close and searching a scrutiny the Select Committee has made of the organization of civil defence, and how truly thinking minds have surveyed these problems. The Report indicates, indeed, that the right type of organization has been evolved, in the regional commissioners, to deal with the emergency problems which arise in heavy and sustained raids, calling for rapid, decisive directions. It is for our representative institutions to attest once more the swiftness of their capacity to respond to constructive criticism, to remedy proved weaknesses, and to strengthen and extend where required to such fields as food supply, housing, evacuation, transport and other services which may be required to deal with the social effects of severe attack, the co-operation and co-ordination which regional and central authority have been proved able to secure. Democracy must prove its fitness by its ability to learn from experience and its swiftness in applying that experience to meet changing needs.

RUTHERFORD—THE HERO AS MAN OF SCIENCE

Lord Rutherford
By Dr. Norman Feather. ('O.M.' Series.) Pp. x + 195 + 8 plates. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1940.) 5*s.* net.

RUTHERFORD'S grandfather had been one of the early settlers in New Zealand. His father owned and lived upon a flax farm in a rural district of South Island. Ernest, born in 1871, was the second son and fourth child in a family which was large, even by the more exacting standards of seventy years ago. At the time of his birth the white population of New Zealand was little over a quarter of a million, and twenty years earlier it had been little more than a tenth of this. Nevertheless, owing to the progressive spirit of the early settlers and to their interest in education, Rutherford was able to receive a more than adequate grounding in science, and even to undertake original research, before he left the country at the age of twenty-four.

He entered Nelson College in 1887 from the State school at Havelock, as the holder of a Board of Education scholarship, and in 1890 he proceeded to Canterbury College, Christchurch, with a scholarship awarded by the University of New Zealand. In 1895 he arrived at Cambridge, the award of an 1851 Exhibition Science Scholarship having enabled him to seek wider opportunities for research. He had then already carried out promising experimental work in electromagnetism, and begun experiments on Hertzian waves, using an ingenious magnetic detector of his own designing.

Rutherford resumed these experiments in Cambridge, with outstanding success, but soon became attracted to the new subject of gaseous ionization and a little later to radioactivity, which became his life-work. The pioneer work on gaseous ionization, which he did in collaboration with J. J. Thomson, was important enough in itself; to Rutherford, however, its main importance was that it provided a natural stepping-stone to the study of the α- and β-rays, which he discovered in 1898. At this stage his work was interrupted—but, characteristically, only by the barest minimum of time required for travelling—by his departure to Montreal, where he succeeded Callendar in the Macdonald research professorship of physics at McGill University.

The rest of Rutherford's life was spent in the successive occupancy of three important chairs—nine years at McGill, twelve in Manchester, and just over eighteen in Cambridge as Cavendish professor. The outstanding contributions he made to physical science in these three periods are now well-known chapters in the history of science; McGill saw the birth of the theory of radioactive transformations and the elucidation of the main radioactive series, Manchester the beginnings of the nuclear atom and the first experiments on nuclear disintegration, and Cambridge the development of the large-scale attack on the problem of nuclear structure.

Rutherford came at an unusually early age to be recognized as one of the great leaders of physical science. He was a tremendous worker, and his unflagging enthusiasm served as an inspiration to steadily increasing numbers of physicists who were attracted to his laboratories, and to generations of students whom he trained for research. Much of the experimental work which established his views on atomic and nuclear physics was carried out in his own laboratories—in the earlier days a great deal with his own hands and with the simplest of apparatus. He was above all a great experimental genius, and he seemed to progress without effort from the use of electroscopes made with cigarette tins to the large-scale heavy electrical apparatus necessary for modern nuclear research. He had a genius, too, for acquiring money and materials for the work he wanted to do, and perhaps in his later years too much of his time and energy were occupied in getting and spending of this kind. This was in striking contrast to his lack of interest in money for its own sake; so far as concerned his personal finances, he was uncovetous and disinterested almost to the point of eccentricity.

The progress of his scientific work was punctuated by an unusually large share of academic and official honours—and Rutherford quite frankly and fully enjoyed all that came to him, and liked his friends to rejoice with him. Honorary degrees and memberships of learned societies from all over the world were showered upon him. He was elected to the Royal Society in 1903 (serving as president during 1925–30), he received the Nobel Prize (for chemistry) in 1908 and he was knighted in 1914. He was awarded the Order of Merit in 1925 and raised to the peerage, as Baron Rutherford of Nelson, in 1931, thus receiving the highest heritable honour accorded to pure physics in England (so far accorded very infrequently, and never yet to a physicist with male issue). He was president of the British Association in 1923, and but for his tragically sudden death he would have served as president of the Indian Science Congress in January 1938.

A career like Rutherford's lends itself obviously —indeed, too obviously—to biographical treatment in a wide variety of styles, from the coldly scientific to the sensational pseudo-scientific, passing by the way the morally uplifting (Samuel Smiles and "Log-Cabin to White House" are models which leap to the mind). The "O.M." series, to which the present volume belongs, dictates a moderately severe, though not too technical, kind of treatment, and does not entirely exclude the element of moral uplift. The author is at pains to point out that his "emphasis all through is on Rutherford the Scientist". This is obviously where Dr. Feather's preference would in any event lie, especially as the details of Rutherford's life, and much of his correspondence, are already available in Eve's official biography published by the Cambridge University Press (see NATURE, March 2, 1940).

By following the plan thus indicated, Dr. Feather has succeeded in compressing into a quite small volume a remarkably complete account of Rutherford's main achievements and, more important still, a connected study of the development of Rutherford's ideas and of the way in which he contributed so largely to the changing of the whole face and trend of atomic physics. Chapter i, on "The Outlook of the Scientist", is an excellent introduction which will help the general reader to an appreciation of the ways in which Rutherford's work impinged upon and modified contemporary scientific thought.

Fortunately, in spite of obvious restrictions of space, Dr. Feather has not entirely suppressed "Rutherford the Man" in favour of "Rutherford the Scientist"; indeed, as Sir William Bragg hints in his foreword, in Rutherford the complex of man and scientific worker was never very completely dissociated. The reader should therefore get from this little book a very fair impression of the combination of qualities which made of Rutherford so inspiring a leader. Indeed, much may be learnt from the well-chosen illustration facing page 186, a snapshot of Rutherford in the laboratory, "discussing the day's results" with two research men. This (fortunately) is much more characteristic of Rutherford than the portrait facing page 128.

Dr. Feather's interest in the history of science and his intimate knowledge of, and association with, much of Rutherford's work have enabled him to do full justice to his theme. It is one of the most fascinating stories in the history of physics—all the more so because Rutherford's mind, far more than that of most men of science, seemed at times to work quite intuitively. Nearly all his life he was doing pioneer work in virgin forests, and the magnitude of his completed performance would have been much less if he had not possessed a remarkably shrewd physical insight which preserved him from wasting time and effort in 'barking up the wrong trees'. Dr. Feather has said this, and more, in much more elegant fashion; the reviewer has ventured to express it in the words which he thinks Rutherford would himself have chosen.

This is a book that was well worth writing, and Dr. Feather is to be congratulated upon and thanked for the way in which he has written it.

H. R. ROBINSON.

EDUCATION OF THE FUTURE

The Future in Education

By Sir Richard Livingstone. (Current Problems.) Pp. ix+127. (Cambridge: At the University Press, 1941.) 3*s*. 6*d*. net.

SIR RICHARD LIVINGSTONE has made a notable contribution to educational thought, although he himself would disclaim any suggestion of originality in his views, since his inspiration comes principally from the writings of Plato, Aristotle, Shakespeare and Milton, together with the main teachings of Christianity. He is concerned only incidentally with the organization of education, but in a style remarkably pleasant and illuminating he deals with those problems which are almost eternal. Work in the schools, he says, is merely preparatory for what should come later as experience accumulates and as the mind expands to comprehend ideas which are complex in themselves and of deep significance, such as we find particularly in social questions, policies and philosophy. He attaches great importance to the fertilizing influence which experience exerts upon knowledge. Too many ideas, which Whitehead would term inert, are plastered on to the young mind, only to fall off again; while even undergraduates are not yet mature enough in their experience of life to comprehend fully the information with which their minds are loaded.

Many of the views to which the author gives expression in his earlier chapters should be taken to heart by teachers of science. Only too frequently their conception of what should constitute a liberal education becomes lost beneath a mass of facts and of abstract principles which fall right outside the student's own experience, and which have no immediate bearing on human life, whether we are thinking of their technical application, or more especially of the wider field of general thought. Whole masses of detail might be jettisoned from science text-books, making room for broader and more entrancing vistas, with a great gain in educational efficiency, and considerable relief to the mind, particularly in the case of those students who will never take up science in any vocational sense ; and, after all, these pupils are the real testing-ground for the educational value of science.

Having indicated what in his opinion are the chief deficiencies in our present system of education, Sir Richard Livingstone then proceeds to suggest possible remedies. A first essential would seem to be part-time education for all until about the age of eighteen. But a far greater need is for the expansion of facilities for the education of adults who from their own experience are in a position to appreciate the ideas and forces which control and determine their existence. Something of this kind has already been achieved by such organizations as the Workers' Educational Association, the Women's Institutes, the Community Centres and the various Guilds, but at present their work is conceived on too narrow a basis, lacking both cohesion and continuity. In their place the author would like to see something analogous to the People's High Schools in Denmark, which, designed entirely for adults, are residential, non-vocational and essentially a spiritual force. Yet, in attributing much of the recent social and economic progress in Denmark to the People's High Schools, Sir Richard Livingstone has not given sufficient weight to the special conditions obtaining there, particularly when the schools were first set up. As he admits, they have made little progress in the towns only a few miles away, and there really is a good deal less work on the farms in Denmark in winter. Besides, Holland has experienced a similar economic development without the aid of such schools, and in Great Britain the public schools with comparable educational ideals have done little to foster any spirit of co-operation.

Nevertheless, the idea of establishing some form of adult schools in Great Britain deserves careful consideration. Industrial conditions now stand in their way, but they might develop most easily as an outgrowth of our Summer Schools. Liberal ideas are more likely to take root in a residential and social atmosphere, with a tinge of the recreational, and one in which the needs of exact scholarship are not so pressing. It might then be possible to link these schools up with other organizations catering for the already educated adult. The present system of summer schools and conferences for professional people the author would like to see extended to cover all those who, passing beyond middle life, and often holding important offices, are in danger of mental ossification and need to be kept abreast of the times.

So far Sir Richard Livingstone has won and retained our admiration for the lucidity with which he has presented his thesis, the major part of which has our unqualified support. It is when he turns to the means and ends of education that grave doubts arise. While not wishing to banish science, mathematics and modern languages from the curriculum, he accords to them a subordinate role, particularly for adults, since, he maintains, they are concerned more with the means by which man lives than with man himself. But "before the student of literature, philosophy, and history are displayed *all* the forces and ideas that governed man, personal, religious, or political". Here his judgment seems to have deserted him. History, literature and politics we can only see through the window of the present, in colours ever changing with the progress of scientific investigation. In isolation these subjects have no personal centre of gravity. What poem or poet are we to take as our standard, what character in history, or philosophical principle as our guide ? That a poet enriches life everyone will concede, but that he sees more deeply and more nearly to the truth than other men is a very doubtful proposition, for on such a subject as a sunset in Italy there could be as many different poems as there are poets. No one has yet discovered what poetry really is.

This leads us on to a consideration of the final ends in education. These the author maintains have been stated many times in the world's history, and are to be found at their best in Greek thought and in the Christian faith. They might be summed up in the conception of the Supreme End, something similar to what Milton had in mind when he wrote, "To know God aright and out of that knowledge to love him, to imitate him, to be like him as we may the nearest, by possessing our souls in true virtue." Here Sir Richard Livingstone presents his case with a serenity of mind singularly out of touch with the profound spiritual questionings which beset the modern world. To many of us Milton's words appear as great literature, but their relevance to present-day problems is distressingly vague. For centuries now scientific investigation has been at work altering the basis of fact upon which the general principles of politics, philosophy and moral conduct are based, and with them the detail of their application. As the reviewer of J. S. Huxley's latest book recently stated in *The Times Literary Supplement* of April 12: "Naturally the science of theology needs restatement from time to time in the light of new facts." Where then is the tangible basis, except in the facts, which themselves are subject to constant revision? Faced with the spiritual morass of the present times it is hopeless to look for salvation to the past. Parents and children cry for new subjects in the curriculum, while the Churches empty, not because the people have gone astray, but because the interpretation of knowledge fails to keep pace with its accumulation. Sir Richard Livingstone, who expresses a great admiration for Masaryk, would find this point elaborated far more ably if he would turn to Masaryk on "Thought and Life".

R. Weatherall.

THE SPIRIT OF ANALYSIS

A Text-Book of Qualitative Chemical Analysis
By Dr. Arthur I. Vogel. Second edition. Pp. xi+486. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1941.) 10*s*. 6*d*.

Students of chemistry usually begin their working lives with the study of qualitative analysis, carried out too often in crowded laboratories with inadequate equipment: it is the equivalent to "grubbing weeds from garden paths with broken dinner knives". Such education is supposed to make "better men than you or I" doubtless because of its practical basis, but to-day we are sufficiently enlightened to wed practice with theory from the beginning and to realize that the more one understands what one is doing the greater the interest in the task becomes.

The writer, like many others, began to learn analysis with an unknown substance before him and a set of tables full of horrible abbreviations which was followed meticulously. He learnt many facts but little manipulative skill and there was no time for reasoning. When Ostwald's famous and best book came into his hands a few years later it was a revelation; nearly everything had been missed during a dull period when chemistry had appeared unattractive. Manipulative skill, the first essential of a would-be researcher, had to be learnt during organic preparations.

The moral of all this is that qualitative analysis has a true spirit and it must be taught in such a manner as to cultivate this. The reviewer is evidently not alone in holding this view for it is the basis of Dr. Vogel's text-book, which has passed into a second edition in little over two years and has been praised by teachers and reviewers. The new edition contains many additions which add to its completeness and value, such as extended accounts of spectroscopic and of microqualitative analysis and of spot tests, all of which are proving helpful in days when the chemist ventures greatly with the smallest possible quantities of materials.

Analytical chemistry, though the oldest branch, and forming a profession of its own with proprietary rights and a society of high standing, is yet neglected academically. There is no professorial chair in the subject in England, as the President of the Institute of Chemistry has just emphasized, announcing at the same time that the subject now forms a branch in which candidates for the associateship of the Institute can be examined. We have emphasized the importance of skill at the bench and it is much more so in these days when work is on the microscale in relation to the natural substances which are being studied. The many Englishmen who worked in Germany forty years ago, often with the aid of an 1851 Exhibition, were almost without exception far more skilled in bench dexterity than the German students whose education in analysis had been on similar lines. In passing, it is interesting to note that nearly all the young men who to-day appear as authors of outstanding researches or books of merit are on record as holders of one or other of the various research fellowships now available. There is much evidence that these are fulfilling their purpose.

There is no point in any detailed reference to Dr. Vogel's pages—practice and theory are so intermixed that one can open the book almost anywhere and read a few pages or paragraphs with interest. The subject is shown to have a soul, a purpose as well as a body—the manipulations take on the guise of an art and a craft instead of being mechanical operations. We have the feeling we would like to begin chemistry all over again.

One last word—these necessities, for they are far more than ideals, mean bigger and better laboratories and perhaps smaller classes. Governing bodies must be educated that laboratories are more useful than lecture theatres, and that theory may be taught at the bench though practice is not learned by listening to lectures alone.

E. F. Armstrong.

(1) Some Problems in Adsorption

By J. K. Roberts. (Cambridge Physical Tracts.) Pp. x+120. (Cambridge: At the University Press, 1939.) 7*s*. 6*d*. net.

(2) Magnetism and Very Low Temperatures

By H. B. G. Casimir. (Cambridge Physical Tracts.) Pp. viii+94. (Cambridge: At the University Press, 1940.) 6*s*. net.

(1) THE first of these little volumes deserves notice because its author writes with first-hand knowledge of his subject and because it is such a helpful survey of experiments and results which do not appear to be conveniently collected elsewhere. Our views on adsorption processes are changing so rapidly that this tract might well be used as an introduction to the more recent treatment of the subject by the author in his article in the current issue of "Reports on Progress in Physics", vol. 7. This combination will provide the reader with an excellent account of the present state of the subject.

(2) The second tract is likewise written with expert knowledge of its subject-matter. It reviews the methods of producing and results of adiabatic temperature changes obtained by demagnetization processes with paramagnetic salts at very low temperatures. It includes a valuable theoretical discussion of the behaviour of paramagnetic ions with special reference to the Lorentz and Onsager fields, and a short account of the theoretical aspects of relaxation phenomena in paramagnetics.

L. F. B.

University Physics. Part 2: Heat

By Dr. F. C. Champion. Pp. vii+148. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1940.) 5*s*. 6*d*. net.

AS the second volume of a series of books primarily intended for students taking a first- and second-year course in physics at a university, one scarcely expects to find space taken up with references to elementary work which has no doubt been done by a student at a much earlier stage; such space could probably have been used to better advantage. Thus in the first chapter mention is made of various types of thermometers, but a description and discussion of these types is deferred to a later part of the book; surely this must be a little irritating to students. Also the table on pp. 8–9 comparing the various thermometers would probably be better appreciated after all the thermometers had been dealt with. The treatment of the various topics follows a logical order, though probably the chapter on radiation could have followed immediately that on conduction.

The above observations are not meant to detract from the merits of a really useful book, which is sound and attractively produced. The diagrams throughout are good and clear, and the chapter on thermal conductivity is especially good.

Dr. Champion makes an excellent point in stressing the importance of reading widely to acquire experience of different methods of treatment, and it is good to realize that there is a tendency towards less formal lecturing, and more study on the part of students; the art of study should be developed and encouraged.

Experimental College Physics: a Laboratory Manual

By Prof. M. W. White. Second edition. Pp. xvi+383. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 19*s*.

THIS rather high-priced book, which is beautifully bound and produced, is a laboratory manual not apparently designed to cover any special examination course, but it appears to be quite suitable for students of post-matriculation standard. All branches of physics are represented in the course (though the section on sound is rather thin), and if a student has the time and the facility to deal adequately with the point raised in each experiment, the course should prove a most valuable one. The book is not merely a compilation of directions for performing experiments, but it includes also the theory underlying each experiment, a description of the apparatus needed, and suggestive questions and problems. An especial emphasis is quite rightly placed upon the evaluation of errors involved in the various experiments, and the whole course certainly encourages a student to appreciate the possibilities and limitations of the scientific spirit and method of investigation.

In some experiments rather specialized apparatus not likely to be found in all laboratories is used, but such apparatus, which in certain cases is rather ingenious, is designed for precision results; in a course of this standard this may not be altogether a desirable aim.

One is struck by the thoroughness with which the task has been attempted, and there can be no doubt of the tremendous enthusiasm of the author for his work.

Economic Geography of South America

By Prof. R. H. Whitbeck, Prof. Frank E. Williams, assisted by Prof. William F. Christians. (McGraw-Hill Series in Geography.) Third edition. Pp. xi+469. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 24*s*. 6*d*.

SOUTH AMERICA offers great scope for economic development from the European point of view. Too much that is written about that continent has a commercial bias or a political colouring. Thus a purely objective study has much value to students. The present volume is nominally a second edition, but in reality is largely a new book. The survey has been done with much care, with due emphasis on the physical and climatic background, which explains much of the economic geography of the South American republics. Most of them are exporters of raw materials and food and importers of manufactured goods, and thus are of great importance to industrialized lands. Lack of population and undeveloped power resources so far restrict manufacturing activity, but even this is tending to develop, and in time to come South America may be more self-contained than at present.

The book is well balanced and well informed, though perhaps more space might be devoted to an account of the racial ingredients of the population. Surely also the little colony of the Falkland Islands merits a few pages.

BIOLOGICAL ADAPTEDNESS AND SPECIALIZATION OF INSTINCTIVE BEHAVIOUR*

By Dr. E. S. Russell, O.B.E.

INSTINCTIVE behaviour is to be regarded, from the biological point of view, as one of the means through which the animal fulfils the biological ends of development, maintenance and reproduction. Now as each species of animal fulfils these ends in a particular way, being after its kind a functional and ecological specialist, we may expect to find that its instinctive equipment, its predisposition to particular perceptions and actions, is also specialized and adapted to its functional requirements, and to the particular environmental complex in which the species normally lives, at different stages of its existence.

It is usual to think of 'adaptation' or adaptive specialization in terms especially of the visible 'characters' of the animal such as its protective coloration. But this is clearly a very superficial view. It is, quite obviously, the animal as a living entity, throughout its entire life-cycle, including reproduction, that is 'adapted' to environment, and if a sufficient number of individuals were not so adapted, the species could not survive.

Adaptation, or adaptive specialization, is therefore not simply a matter of superficial 'characters', such as may be supposed to have 'survival value', but of the behavioural, physiological and morphogenetic activities of the animal throughout its whole life-cycle. Adaptive specialization rules throughout the whole life-history. There must be no weak link in the chain, otherwise the species disappears.

Consider the main points in the life-history of parasitic Hymenoptera (families Chalcididæ, Braconidæ, Ichneumonidæ). These insects having taken up a highly specialized mode of existence, have occupied a very special ecological niche, for they pass their larval stages in the living bodies of various insect hosts, parasitizing them in the caterpillar or chrysalis stage and in some cases in the egg itself.

If the parasite species is to survive, the sexes must be able to find one another and effect the fertilization of the egg; the female must be able to find and oviposit in a suitable host—a host in which her larvæ can survive and develop. She must have the necessary organ for inserting her egg into the body of the host, a sharply pointed ovipositor, and the impulse to plunge it in. In its turn, the larva must be adapted in structure and physiological functioning to live and grow in the very special conditions afforded by the interior of the host. That it is so adapted and specialized is well illustrated in the excellent description given by Cameron[1] of the larva of the ichneumon *Glypta hæsitator*, a parasite of the caterpillar of the pea-moth *Cydia nigricana*, in which he directs special attention to the adaptations in the cephalic skeleton and jaws. This apparatus is more developed in the first and fourth stage larvæ than in the second and third; in the first stage it is required for the act of eclosion from the egg, and in the last stage for feeding on solid food. "In the earlier stages," he writes, "the parasite larva obtains nutriment in a fluid condition, but in the last instar it has to live mostly on solid food, consisting of the remaining tissues of the host, such as the fat-body, etc., and for this work it requires stronger mandibles and a stronger supporting skeleton. Stronger mandibles are also useful when the time comes for it to break through and cast off the skin of its host. The arduous task of cocoon spinning is carried out in this stage. The latter function is specially provided for by the transformation of the salivary gland and its opening into a silk gland and a spinneret, respectively. . . . In the second and third stages the cephalic skeleton is present, but the parts are only weakly chitinized, from which it would appear that it has no special function to perform save that with each moult the parts get successively larger in preparation for the work awaiting them in the final stadium."

Here we have an excellent example of that proleptic or anticipatory formation of special structures to meet coming needs which is so striking a feature of the directive process of development; and it seems clear that without these special provisions, and many others of an adaptive kind, the larva could not successfully carry through its development.

Turning now to the behavioural adaptations concerned in the finding of a suitable host, we see at once their vital importance for the continued existence of the species. From the very fact that a parasite species continues to exist we can infer that a sufficient number of females manage regularly to find and oviposit in suitable hosts. They must have therefore the impulse to seek for such hosts, and the power to recognize them in some way, by their specific smell, or by their size and shape and texture, or by some other characteristic. Every species that persists and maintains itself successfully must be, as regards its females, biologically adapted and specialized to find and parasitize a host or hosts in which its offspring can develop normally. Some species limit themselves to a single kind of host ; others successfully parasitize a large number. There are therefore degrees of specialization or restriction.

---

* Substance of the presidential address before the Linnean Society of London on May 24.

Let us consider the nature of this instinctive predisposition. It seems unreasonable to suppose that the ovipositing female is guided in her choice by explicit knowledge that such and such a host is a suitable one for the development of her egg, and acts with intelligent purpose. She knows nothing of her egg *qua* egg, that is, as something which will develop into a larva and adult ; it is to her merely 'something to be laid'. She can know nothing of the nutritive relations that will be set up between her larva and the host. The animal seems inconceivable that the female can have such knowledge ; she is an insect, not an entomologist. The fact that instinct can err and is easily led astray in abnormal or unusual situations is sufficient to show that no supernatural faculty of direct intuitive knowledge is involved, as Bergson believed.

We see then that instinctive behaviour is not a matter of the intelligent and purposive pursuit of ends ; it is a matter of specialized and pre-adapted capacity—the capacity or predisposition to perceive certain things and events, and to act in a particular manner with reference to them. It knows what to do about them, though it does not know why. As Spaier[2] has well said, instinct is characterized by *savoir faire*, as distinct from *connaissance*.

Instinct is specialized on the perceptual side as much as on the executive. The female having the instinctive disposition to seek out a particular host is guided by some perceptual clue which is normally associated with that host alone, and this clue may be both simple and normally adequate—a specific smell for example, associated with an object of a certain size and shape.

The chalcid *Microplectron fuscipennis*, for instance, is restricted in her attacks to the resting larva of the saw-fly Diprion, which is enclosed in a cocoon[3]. She does not, however, seek what we think of as 'a cocoon of Diprion' ; she cannot form a concept such as this ; she simply seeks an object (or manipulandum, as Tolman would call it) which is attractive to her as 'something to be pierced' with her ovipositor, an object that has this particular functional valence.

She is able to distinguish this object from other similar objects, by means of a few sensory characteristics, such as smell, shape and texture, which are not necessarily those which we perceive as diagnostic of a Diprion cocoon. She is adapted and specialized in her sensory capacities in such a way as to perceive and be attracted to certain specific objects (which are biologically suitable for the development of her eggs), and to be impelled to oviposit in them, in preference to other similar objects. Such objects alone have for her oviposition valence.

This specialization and adaptedness of instinctive behaviour on the perceptual as well as on the executive side is obviously just one aspect or expression of the adaptive specialization which characterizes the individual and the species as a whole.

Correlative with the fact that animal species are adaptively specialized is the fact that they normally live in a more or less definite and specialized environment or ecological norm, which is optimal for their vital requirements. This may be extremely restricted, as in the case of caterpillars which feed on one kind of plant, or live in a specialized environment, as do the leaf-miners ; or it may be very wide, as in the case of many far-ranging birds and fishes. It is impossible to define it except in terms of the functional needs and requirements of the species, with which it is correlative. It may alter radically in the course of the individual life ; many teleostean fish completely change their habits and habitat when they change over from a free-floating planktonic existence to a life on the bottom of the sea, and drastic changes in life-habits and the ecological norm are notoriously shown by holometabolic insects.

It is a very interesting problem of animal behaviour to determine how a species finds and remains in the ecological norm appropriate to each particular stage of its life. This is too big and comprehensive a question to be tackled here in detail, but I propose to consider in outline some of the ways in which animals contrive to lay their eggs in the special ecological norm which is suitable for their development.

In the simplest case, the animal deposits its eggs within its own ecological norm ; the pond-snail Lymnea, for example, lays its gelatinous masses of eggs on the vegetation of its home pond ; many shore fish, like the blennies and gobies, fix their eggs in crevices of the rocks within their normal habitat. But it often happens that the ecological norm for the eggs and larva is quite different from that of the adult ; especially is this the case with insects that undergo metamorphosis, and with marine animals that have pelagic larvæ. In such cases the female usually selects for oviposition either the ecological norm required by the larvæ or a place from which this norm can be reached. An insect, for example, may oviposit directly on the food plant of its larva, or on the substance, such as dung or carrion, on which the larva feeds. If it has an aquatic larva it may oviposit on the surface of the water, like many dragonflies, or it may insert its eggs in plants growing in or near the water. Many marine fish normally spawn up-current, in such a position that their floating larvæ are usually drifted down towards an area in which they find suitable conditions for their later development and growth[4].

Here are two examples of the selection by insects of the *general* environmental conditions required by their larvæ. A species of tsetse fly, *Glossina palpalis*, found on the shores of Victoria Nyanza, feeds by preference on reptilian rather than mammalian blood; it is most numerous on the open beach and banks of streams which crocodiles and Varanus frequent. Here also are found its pupæ in greatest numbers, adjacent to the food supply when they hatch out. Hale Carpenter[5] made a careful study of the exact locations where the females deposited the mature larvæ they produce. He concluded that they sought out with great accuracy areas of loose, dry soil, well shaded, with a surface exposed to the air, within a few yards of high-water mark, but beyond the reach of the water.

Similar care in the selection of a suitable place in which to lay her eggs is exhibited by the flying imago of the ant-lion, *Myrmeleon formicarius*. On warm summer evenings in the twilight the females are to be found flitting round the sun-warmed sandy spots where were situated the funnels in which they lived as larvæ[6], and in these areas they deposit their eggs. These spots must be warm and dry and sunny, preferably sheltered from the rain by an overhanging bank or tree, and floored with sand or dust in which the larvæ can dig their conical funnels. If the female chooses an unsuitable spot, the larvæ on hatching will move about until they reach their proper ecological niche, guided by light and temperature.

Selection of a position for egg-laying from which the young will normally reach their ecological niche is well illustrated by the cicadas. In their immature state, which may last for many years, as in the famous 'seventeen year locust', these insects live underground, in narrow vertical shafts, getting their food by sucking the juices of roots. When the time comes for metamorphosis, the nymphs emerge from their burrows in the late spring, and immediately seek out some plant or tree, which they climb and to which they cling, while they burst out of the nymphal shell as fully formed imagos. *Magicicada septendecim*, according to the careful investigations of Andrews[7], treks steadily and persistently towards the nearest tree—which it perceives visually, not as a complex thing such as a tree appears to us, but "as an area of greater or less light contrasted with the background". If it is prevented from reaching a tree it will climb up some other vertical object, like the palings of a fence, chicken wire, or tall grass stems, and metamorphose on them. "If it encountered a man lying down," writes Andrews, "it surmounted him and walked on over him to the tree, but if the man were standing up beneath the tree the cicada might climb up him and even transform fastened to his clothing, without reaching the tree" (p. 281). So what this species of cicada seeks is not "a tree", but some vertical object, standing out against the visual background, which it must climb. In natural and normal conditions this object is, generally, a tree, and for another purpose, that of oviposition, a tree is for the female the biologically suitable object. This is reached through very simple, but normally adequate, behaviour—behaviour adapted to a normal environment, which contains more trees than, for example, posts.

All the kinds of cicada insert their eggs in the tissues of plants, to the number of several hundreds, either in the twigs and branches of bushes and trees, or in the stems of herbs or grasses. They are not very specific in their choice, though the European *Tibicen plebeia* often selects the dry stems of the asphodel for oviposition. With respect to *M. septendecim*, Andrews tells us that they "commonly work upon twigs of about the thickness of a lead pencil and often of last year's growth. When they use smaller twigs this frequently works disaster as the twig breaks off and hangs with dead leaves or falls to the earth" (p. 287), and the eggs laid therein do not develop. Sometimes cicadas will lay eggs in quite unsuitable places; *Melampsalta cingulata* has been known to oviposit in an apple[8], *Tibicen erratica* in the boards of a shed roof, and on the handles of hoes left standing during the dinner hour. More remarkable still, *M. septendecim* has been seen trying to insert eggs in the iron rod of a bridge, extruding seven.

These scattered observations suggest that the instinct of the female when ready to lay is simply to climb upwards; normally this means climbing up a tree or a bush or a stem, and normally this action will lead her to a suitable site for oviposition. When she comes across man's handiwork her instinct to ascend does not lead her to a suitable spot—but she oviposits all the same. Instinctive behaviour is adapted to the normal or most usual situation to be encountered by the species, and takes no account of the unusual.

The cicadas do not lay their eggs in the ecological niche inhabited by the larvæ or nymphs, which, as we have seen, is underground in proximity to the roots of trees and other vegetation on which they feed. They lay their eggs, however, in places from which this habitat can be reached, by the simple device of falling to the ground and burying. The larvæ hatch out as tiny sheathed nymphs, the size of a flea, and climb out of the egg-nest towards the light, moving outwards or upwards to the ends of the twigs; then after a varying period of time, a quarter of an hour to several hours, they let themselves fall to the earth, where they immediately creep down any crevice or actually dig themselves in.

Snodgrass[9] gives the following description of the behaviour of newly hatched *Magicicada septendecim* which he placed in a pan of earth. "These at once proceeded to get below the surface. They did not dig in, but simply entered the first crevice that they met in running about. If the first happened to terminate abruptly, the nymph came out again and tried another. In a few minutes all had found satisfactory retreats and remained below. The avidity with which they dived into any opening that presented itself indicates that the call to earth is instinctive and imperative with them once their feet have touched the ground" (p. 408). Andrews[7] describes how the newly hatched nymphs of the same species squeeze themselves into crevices and cracks in the ground, fall down or climb down the holes left by their parents on emergence from their seventeen years sojourn below ground; he found that they could actually dig into the ground, slowly but surely.

Active burrowing has been observed also by Fabre and by Myers. Fabre's specimens (*Tibicen plebeia*) ran around for two hours before burying; when they were dug up they re-buried themselves immediately. Myers's young nymphs of *Melampsalta leptomera* placed on moist sand buried at once, twelve disappearing under the surface in ten minutes; after twenty-four hours some were three inches down.

Another example of oviposition in a place from which the newly hatched insect can, usually, reach its ecological niche is afforded by the dragonfly *Lestes viridis*, the larva of which is, like those of all dragonflies, aquatic. The female lays her eggs in the autumn on the underside of sallow or osier stems, forming galls. In the spring the larva hatches out, enveloped in its pro-nymph sheath. "By a strong bending of the body it jumps clear of the stem, and usually falls into the river. If, however, it falls on to the ground, it skips vigorously about, until, aided by the slope of the ground towards the river, it eventually jumps into the river"[10]. There it floats back downwards until it emerges from its sheath and takes up life on the bottom.

Deposition of eggs directly on the food plant or on other objects or substances suitable for the growth of the larvæ is of course a widespread phenomenon in insects. Here are a few examples.

In the Lepidoptera the female generally lays her eggs on the food plant or plants of the larva, and this is often found by its smell. The following examples I take from Hering's book[11].

The goat moth *Cossus ligniperda*, the caterpillars of which live in the woody tissues of willow and other trees, seeks out injured parts of the trunk on which to lay her eggs. The wound tissue being rich in nutritive substances forms a good spot for the larva to begin life, and from such spots it later burrows into the wood. Generally fermentation occurs at the wound, with production of acid and a characteristic smell. It is this smell that attracts the moth. One has been observed to settle down on a streak of vinegar on the tree trunk and attempt to find the wound in which to lay its eggs.

The butterfly *Papilio demoleus* normally oviposits on the orange-tree. It has been seen to lay eggs on various plants and on the ground to leeward of a strongly scented tree, these being so strongly impregnated by the smell as to be for the butterfly functionally equivalent to the parts of an orange-tree.

Females of the moth *Acronycta auricoma* kept in a box with their food plants were found to lay, not on the plants, but on the sides and bottom of the box, which was presumably impregnated with their smell. A similar state of affairs was found by Thompson and Parker[12] when studying host selection in the corn-borer *Pyrausta nubilalis*; females confined in cages with their food plant laid a considerable proportion of their eggs on the wood-work and the plant pots. These observations suggest that the chief valent characteristic of the food plant is its smell.

The fruit-fly *Drosophila ampelophila* lays its eggs in fermenting fruit, which it finds by smell. The experiments of Barrows[13] have shown that it exhibits an optimum response to a mixture of ethyl alcohol of 20 per cent and acetic acid of 5 per cent, which are about the strengths found in fermented apple juice.

A very interesting case has been described by Miss Ilse[14] from which it appears that the female cabbage white butterfly *Pieris brassicæ* may be guided in part by colour sense in finding the cabbage and other plants on which it lays its eggs. When hungry these butterflies give a specific feeding response to red, yellow, blue and violet colours such as occur in flowers; when they are set on egg-laying, however, they give a peculiar 'drumming reaction' with the first pair of legs, and this is elicited by any object which shows colours ranging between emerald green and greenish blue. During this phase yellow and pure blue colours are disregarded; the drive to egg-laying shifts attention to greens and greenish blues, characteristic of the leaves on which it normally oviposits.

A similar case was described by Knoll in 1922, whose observations are summarized by Bodenheimer[15] as follows: "The colours to which the hawk-moth *Macroglossa stellatarum* is attracted, change, in the gravid female, to that of chlorophyll, and this attraction, coupled with the smell of etheric oils of *Galium*, guarantees the proper oviposition and development of the caterpillars" (p. 48).

Regarding the choice of suitable hosts for their eggs by the parasitic Hymenoptera and Diptera a great deal of interesting work has been done, especially in the field of applied entomology. These insects lay their eggs in, or on, a great variety of Arthropod, chiefly insect, hosts, and their choice of a host may be highly specific, being limited to a particular stage—egg or caterpillar or pupa—of one species or of a narrow range of species. The Chalcid *Ooencyrtus kuvanae*, for example, limits her attacks principally to the eggs of the gypsy moth *Porthetria dispar*, though in the laboratory she will parasitize the eggs of eight other species of Lepidoptera[16]. Or the species may be 'polyphagous', attacking a wide range of hosts; *Compsilura concinnata*, a dipterous (Tachinid) parasite, injects its living larvæ into caterpillars of more than fifty species, including saw-fly 'caterpillars'.

But whether the choice is wide or restricted, the hosts chosen are in general such that the young can develop successfully in them; the choice is adaptive —and may be highly specialized.

That a parasite species in natural conditions rarely oviposits in a host unsuitable for its progeny has been conclusively shown by Thompson[17]. He has examined many thousands of hosts of all kinds, and has found that, with insignificant exceptions, they contained only parasites which are known to be capable of development in the hosts in which they occurred. The evidence indicates, he concludes, "that the choice of the host by the parasite is, in general, both *specific* and *adaptive*. The parasite is restricted to certain kinds of hosts; these kinds are, generally, the kinds suitable for the offspring" (p. 355). The instinctive activities of the parasitizing female are therefore, like most instinctive actions, both adapted and specialized. In normal and natural conditions the parasite will usually choose the right or biologically adequate host. In abnormal conditions, as when it is prevented from access to its normal hosts, it may oviposit in hosts or in objects which are unsuitable.

How does the insect, in natural conditions, find a certain kind or kinds of hosts? We cannot suppose that it knows by intellectual process that such and such hosts are suitable, and we have no reason to think that instinct is a magical faculty which gives the animal intuitive insight into the nature of things. It seems then, as I have indicated before, that the insect must be guided by perceptual clues, to which it is predisposed or pre-adapted to respond, and that these clues, or "sign posts", as Thompson calls them, are normally adequate to indicate the suitable object.

Summing up, we may provisionally conclude that each animal species has an innate predisposition to perceive, and act with reference to, particular objects and events, which alone have valence for it. It appears also that these objects and events are, in normal circumstances, biologically significant in relation to its special mode of living, of satisfying its needs and requirements, and of perpetuating its kind. We have clear indications too that in many cases the biologically suitable object, such as for example the right kind of host in which to oviposit, is distinguished in perception from others less suitable by means of a few valent characteristics, such as a specific smell, size or shape, often linked with one another. These are, for the animal, perceptual or sensory clues or signs, to which it is predisposed, or pre-adapted to attend, and they normally indicate, sufficiently well, the biologically suitable object. These signs are, therefore, *normally adequate*.

The possibilities of perception are of course limited by the animals' sensory equipment. What an animal *can* see depends upon the nature of its visual receptors; one does not expect fine visual perception from a frog or a mouse, or vision at all from an earthworm. The general character and scope of an animal's sensory and perceptual field is clearly determined by its sense organs; an orb-spider lives in a sensory world in which tactile and vibratory impressions are all-important, a bee in a world of specific scents, colours and shapes.

But the point of interest is not so much the sensory limitation and specialization of the possible perceptual field, but the fact that not all the potentially perceptible objects and events in the sensory field are valent, but only, as a rule, those that are biologically significant. Thus the honey-bee is specialized to attend instinctively to the scents of flowers, and cannot be trained to other scents, although its olfactory sense is highly developed; also it pays particular attention to images or figures that resemble or suggest flowers, and much less to images of unbroken contour (refs. in K. von Frisch[18])—it has an instinctive predisposition to seek out flower-shapes.

To many objects and events in its physical environment the animal remains behaviourally neutral; it does not notice them; they possess no valence for it. Only a few events will rouse it to attention and action. Here is an example. The slow-worm *Anguis fragilis* is, according to Wood-Jones and Porteus[19], singularly irresponsive to what goes on around it, "but let anyone who wishes to test its powers of vision . . . arrange that a little grey slug shall wander into the picture and note the instantaneous effect that this produces on the Blind Worm. The little grey slug is a biologically relevant stimulus, since in the ordinary way *Limax agrestis* forms the elected article of diet of *Anguis fragilis*." Now what the blind-worm perceives is not a slug, as we perceive and recognize it, but merely something of a particular size, shape and mode of motion, which has food-valence. We must carefully guard against the fallacy of assuming that animals perceive objects in the detailed and complex way that we do, as continuing 'things', recognizable by a large number of associated characteristics ; the evidence tends to show, on the contrary, that animals may attend to and perceive only one or few characters of objects. That is why their perception sometimes leads them astray.

Many of the so-called aberrations of instinctive behaviour are quite understandable when we realize these two things : (1) that the animal's sensory or perceptual field is often a very simple one, and (2) that *in normal conditions* the events and the objects possessing valence are *usually* objects and events that are biologically significant. 'Aberrations' occur when, in unusual circumstances or by exception, the valent characteristic or clue crops up as a character of a biologically unsuitable object. But the animal does not necessarily confuse the two different perceptual objects—the suitable and the unsuitable ; it may perceive only the valent characteristic which is common to both, and fail to perceive the differentia of the two. Within the limits of its instinctive perception, then, it does not err or make a mistake ; it is misled.

The fact that the sensory or perceptual field is usually a fairly simple one helps in some measure to reduce the mystery of instinctive behaviour ; we have no need to assume that an animal is attuned by heredity to recognize, without prior experience, a highly complex and specific object, such as it appears to us.

STABILITY OF MINERALS IN SEDIMENTARY ROCKS*

BY PROF. P. G. H. BOSWELL, O.B.E., F.R.S.

AS the rocks which form the continental masses are disintegrated by the action of weathering and other geological agents, their detritus accumulates to form sedimentary rocks, ultimately on the sea-bed. In most instances, the constituents of these sedimentary rocks afford a clue to the character of the parent material and furnish information about the probable source and direction of transportation of the detritus (provided, of course, that the investigation is carried out over a sufficiently wide area). In the majority of sediments, especially the coarser types, the bulk of the grains consist, however, of the common mineral quartz, which yields little evidence of a particular source, for it is widely distributed throughout almost all types of rocks. It is able to survive many cycles of erosion because of its high resistance to chemical alteration and mechanical disintegration. But certain other constituents, usually of rarer occurrence, known as the heavy detrital minerals because of their higher density ($>2{\cdot}9$), are of much greater value as clues to origin, for many of them are characteristic of particular rock-types.

Of the many interesting problems that have arisen from the study of the occurrences of these minerals, that of the relative chemical stability of various detrital species is perhaps the most important and urgent at the present time. Deductions about the origin of sedimentary rocks, based on the varying proportions of constituent minerals, rest on the assumption that their present distribution either does not differ greatly from the original distribution (when the sediments were deposited) or has suffered changes which have affected all the minerals to a similar extent. In some cases, at least, such an assumption is unwarranted, for we have good reason to believe that the less stable species gradually decompose in the course of geological time. We find it necessary, therefore, to devise some means of assessing the extent of post-depositional changes in mineral assemblages. Obviously, we can call to our aid experimental work in the laboratory; and the results of such work have shown that minerals vary considerably in their resistance to attack by weak reagents like dilute mineral acids, humic acids, carbon dioxide saturated water and alkalis, although the effects, especially on detrital grains, have not yet been fully investigated. Natural conditions are difficult to imitate, for geological time is not available in the laboratory: we attempt to compensate for this by increasing the concentration of the reagents, but there are obvious objections to such a course. Nevertheless, we can reasonably hope to throw light on the natural processes by making the period of attack as lengthy as is humanly possible; also, we can try to simulate the field-conditions by adjusting the composition of the reagents to that of various ground-waters, and to imitate the resurgent action of their seasonal rise and fall.

---

* Abridged from Part 2 of the presidential address to the Geological Society, March 1941.

Apart from experimental work of this kind, evidence bearing on the question of the post-depositional stability of detrital minerals can be obtained from field-studies. It is furnished by (*a*) the comparison of the varying incidence of mineral occurrences throughout the stratigraphical column, especially the comparison of Recent with older sediments, (*b*) the quantitative study of the various minerals of an assemblage from a particular formation throughout its lateral and vertical extent, and (*c*) the alteration-phenomena, especially as regards the form and surface features, exhibited by individual mineral grains.

Our experience of the considerable resistance usually offered by rock-forming minerals to solution and our familiarity with the ubiquitous occurrence of detrital minerals may lead us unconsciously to over-emphasize their durability. We may find it a useful corrective, therefore, to bear in mind the significance of two important factors, first, the almost unlimited draft on geological time that is available and, secondly, the relatively large surface area that is open to attack in the case of these minute grains. The work of several investigators, including Tamm, Stevens and Brammall, gives point to this latter consideration, for they found that most of the rock-forming minerals are hygroscopic when finely powdered, and are partially dissociated, the water then giving an alkaline reaction. The importance of these examples of hydrolysis at ordinary temperatures and pressures is manifest, for they suggest that, once such minerals are reduced by natural mechanical action to the size of the clay grade, their decomposition will probably be rapid; and, even in their coarser state, the grains are scarcely likely to escape corrosion under the action of ground-waters.

It is axiomatic to say that, other things being equal, the longer the time available for percolating water to act on minerals, the greater will be the amount of decomposition and the more complete the elimination of vulnerable constituents. Several investigators have directed attention to the fact that the relative abundance of certain minerals (such as andalusite, kyanite, the pyroxenes, the amphiboles, etc.) decreases with the increasing geological age of the sediments. Most striking, in this connexion, is the contrast between the mineral assemblages of the Recent or Pleistocene deposits and those of more ancient sediments. The former assemblages are rich in heavy constituents, both as regards variety and abundance, and the grains are often exceptionally beautiful. The number of species identified from an individual sand may be forty, sixty, or even more. In all, about a hundred and sixty rock-forming minerals have been found in sedimentary rocks, that is, practically as many as are known to occur in the parent crystalline rocks, if we exclude species of great rarity. But about forty of these, including the rarer species, can be found only in geologically youthful deposits. As they occur in ancient crystalline rocks, which have undergone erosion in the normal course of events in past epochs, their absence from the corresponding ancient sedimentary formations must be attributed to subsequent decomposition.

Passing to the consideration of the evidence furnished by the quantitative study of the occurrence of various minerals in a particular sediment, I may recall that, when the character of the mineral assemblage was used as a clue to the provenance of the detrital material, the progressive changes in relative abundance and size of grains of significant minerals, as the deposits were traced laterally, were interpreted as an indication of the relative distance from the source-rocks and thus of the probable direction in which they lay. This deduction followed from the assumption that, as the source became more and more distant, the less stable minerals were gradually eliminated in the reverse order of their resistance to abrasion, fracture and chemical decomposition. But any complacency we might have felt about the correctness of conclusions based on such evidence must have suffered a shock when R. Dana Russell published recently the results of his detailed researches on the lengthy transportation of minerals by the River Mississippi. Here we might have expected to get clear evidence of the gradual disappearance of the less stable elements. However, Russell found that the eliminatory effects appear to have been greatly over-estimated, at least with respect to the sand sizes.

The concept that even such 'weak' minerals as the pyroxenes, amphiboles and the felspars are unable to survive more than a few hundred miles of transportation because of abrasion during the journey is quite erroneous. Abrasion produces only minor changes in the mineral composition of Mississippi River sands in 1,100 miles of transport, and even these changes are largely offset by other factors, especially progressive sorting according to size. Similarly, chemical decomposition during transportation also plays but a minor part. The net result is that sands reaching the Gulf of Mexico have nearly the same composition as those at Cairo, Illinois. In order that the general applicability of his conclusions may be tested, Russell pleads for similar investigations of other river deposits, and of beach and dune sands ; we shall await these new results with great interest for, although it has been claimed that the gradual elimination alongshore of certain minerals has been established, the investigations have been less intense than Russell's and the area covered in each case was more restricted.

As the challenge thus thrown out must be met we may find it desirable also to re-investigate in at least the same detail those ancient sediments from which deductions have been made about the source of the material. Although, in certain instances, we may have erred on the side of boldness in framing our postulates, I am by no means convinced, after a fresh study of the European literature, that we have depended on them to such an extent that we have in consequence been led into serious error. In those cases where we have relied on the progressive diminution in size of significant detrital minerals, with or without reduction in variety of constituents (and such cases are numerous), and have taken due account of the grading of the sediment, we have doubtless gone but little astray. Also, for some time past, we have been less inclined to be dogmatic in our inferences about the source of detritus, based on records of mineral frequencies, largely because of our conviction that the potency of post-depositional processes should not be underestimated. In those instances where the grade of a sediment remains approximately uniform as the formation is traced laterally, the question of variation of frequency with grain-size obviously does not arise. The same is true if the grading varies, provided that all grades of the sediment have been subjected to mineral analysis. In either of these cases, a progressive change in the abundance of particular minerals may depend on one or both of two factors, distance of transportation and effects of post-depositional processes. Recent work (for example, that of F. Smithson, referred to below) bids fair to enable us to distinguish between the operation of these two factors.

It is a common experience that heavy minerals are often rare in coarse sands, other than natural concentrates, but are plentiful in less coarse sediments down to the clay grade, their distribution in the various grades being determined by their equivalent hydraulic value. As disintegration proceeds and the deposits become finer as a whole, the heavy minerals may be lost to sight because they have passed into the finest grades. The opportunities afforded for investigating all the grades of a present-day sediment are obviously much greater than in the case of a 'fossil' sediment, for portions of the latter have usually become inaccessible as a result of erosion or burial. Our conclusions must then be based on a part only of the deposit, but it has yet to be proved, from studies of Recent deposits, that they are thereby invalidated.

The survival of minerals after they have been incorporated in a sediment clearly depends on the ease or difficulty with which water can percolate through the deposit. Having regard to its slower passage through fine-grained rocks, we might expect such rocks to remain richer mineralogically, were it not that there is the offsetting tendency for clays, because of their mode of origin as the finest products of decomposition of other minerals, to be deficient in mineral variety. The conditions under which the differential effects of percolation are likely to be greatest are those where sands are protected by an impermeable cover. Not only should we then expect that a considerable proportion of the less resistant minerals would be retained in the sands, but also a vulnerable species (such as apatite, for example) would survive in quantity. Actual observations in Great Britain and the United States have shown this to be the case. The contrary state of affairs should be found in sands lying in a basin of clay, with the resurgent effect of ground-waters in full play.

By intensive study of the petrology of a specially chosen sediment, directed to a comparison of the relative abundance of particular minerals in relation to their 'pathology' and the grading of the sediment, light may be thrown on the efficacy of the post-depositional processes. The formation selected for study should preferably have a well-defined and fairly characteristic heavy mineral assemblage, and have been accumulated in such a way that all parts of its outcrop are approximately equidistant from its source-rocks. Even if these conditions are not exactly fulfilled, valuable results can be obtained from the investigation of a suitable sediment, as witnessed by F. Smithson's attack on just such a problem recently. Briefly stated, his method has been to study theoretically the variations in proportion shown by the heavy minerals as a result of sorting, of mineralogical changes such as decomposition and reconstitution, and of other processes. He has compared these results with the data obtained from the quantitative investigation of natural deposits. The similarities in the results, which are clearly demonstrated by graphical expression, seem too marked to be fortuitous. From his detailed studies of the Estuarine Series of the Jurassic of Yorkshire, he has been able to prepare maps showing changes in a number of mineral characters in 'contour' form.

Among the features thus represented in Smithson's work are the diminution in the richness of the mineral assemblages, in the percentage of samples containing garnet, in the estimated frequency of garnet and in the actual percentage of the mineral, as the middle of the Yorkshire basin is approached. The result of plotting the frequency of apatite is somewhat similar. On the other hand, the frequency of ilmenite + leucoxene, the frequency of authigenic pyramidal anatase and the percentage of zircon showing outgrowths (all secondary features and doubtless post-depositional) increase regularly towards the middle of the basin. Thus the pattern of the maps suggests that, along the tectonic axis (where the rocks are downfolded), there is an oval belt in which certain processes have been most active, leading to decomposition of garnet, the general impoverishment of the mineral assemblage, and certain secondary changes such as the production of outgrowths and new minerals. If all the mineral characters (including size and relative dimensions of grains) are treated statistically one by one and recorded on maps, an interesting result appears. Had the characteristics been preserved as they were when the sediments were laid down, all the maps should have presented, as it were, a picture of the palæo-geographical conditions prevailing at the time of deposition. Instead, we find that, owing to somewhat localized mineralogical changes, many of the maps present a generalized picture of the tectonics of the area, and in some, doubtless, both pictures are confused. If in some cases, then, impoverishment increases in proximity to the middle of structural basins rather than basins of deposition, we can understand how it was that the frequent coincidence of the two types of basins contributed to the widespread belief that progressive elimination of minerals increased with transport and afforded a clue to the distance and direction of the source.

Turning now to the third line of evidence, that furnished by the form of mineral grains, we recall that faceting, notching and fraying of detritals have frequently been recorded from many ancient sediments. These features have been imitated in the laboratory by Bramlette (who treated garnet with hydrofluoric acid) and Mackie (who subjected various minerals to the action of acid potassium sulphate). Although, as compared with natural processes like the attack by ground-waters, such treatment was drastic, its duration was very short. Naturally corroded grains are especially characteristic of certain stratigraphical horizons, presumably where the environment was exceptionally favourable. The type of corrosion, and therefore the form of the grains, differs according to the properties of the particular mineral, and the general composition of the sediment and the ground-water, although at present the relationship is far from obvious.

The angles, where measurable, of the notching or etching are peculiar to the particular mineral, and are related to the directions of crystal axes, optic axes, cleavage, or other determinable properties. Edelman and Doeglas, after investigating a large number of these corroded grains, are convinced that the features are closely related to the etch-figures of the minerals, where they are known, and are 'relict-structures' marking a stage in the process of gradual elimination of the minerals. The features are certainly post-depositional, for their delicacy and fragility are such that they could not possibly have withstood the rough-and-tumble of transportation.

As examples of British stratigraphical formations in which corroded grains are well developed, I may refer to the remarkable etching of garnet in the various sandy horizons of the Carboniferous system, the raggedness of the staurolite in many beds of the Permian and Triassic (in which the garnet is most frequently sub-angular or rounded), the frayed kyanite, saw-edged staurolite and lunate garnet of the Lias - Inferior Oolite sands, and the carious kyanite of the Northampton Ironstone. Numerous other examples could be cited to illustrate the selective character of the corrosion. Probably the phenomenon is related to the composition of the local ground-waters, and its manifestation depends on favourable conditions in the lithology and tectonic arrangement of the rock-succession, but until such relationships have been investigated in detail at particular localities, any discussion of the manner in which the post-depositional processes operate must be largely conjectural.

P.S. Since the above was written, a paper by M. N. Bramlette has appeared in the *Journal of Sedimentary Petrology* for April 1941 on "The Stability of Minerals in Sandstone", which contains many new observations and amplifies the above remarks in several important particulars.

OBITUARIES

Dr. Annie J. Cannon

ANNIE JUMP CANNON, who died on April 13, was born at Dover, Delaware, on December 11, 1863. While still a very little girl her curiosity was attracted towards the stars; and many evening hours were spent with her mother learning the constellations. When she left school, her father, despite the prejudice in those days against the university training of girls, sent her to Wellesley College where she graduated B.S. in 1884. Later she returned to Wellesley as a graduate student and studied physics under Prof. Sarah F. Whiting. After specializing in astronomy for two years at Radcliffe College she was appointed an assistant at the Harvard College Observatory under the inspiring directorship of E. C. Pickering. It was natural that here her interests should have become focused on variable stars and on the study of stellar spectra, the subject which was to become the great work of her life. In 1911 Miss Cannon was made curator of astronomical photographs at Harvard, and in 1938 was appointed William Cranch Bond astronomer, a post created in honour of the first director of the observatory. Though she officially retired from the staff of the Observatory in the summer of 1940, she continued with active work in her old department until a few weeks before her death.

Miss Cannon received many academic honours. Honorary degrees were conferred upon her by the University of Delaware, her own State; by the University of Groningen, Holland; by Wellesley, her Alma Mater; by Oxford, by which university she was the first woman to be honoured with a doctor's degree; by Oglethorpe University; and by Mount Holyoke College. In 1931 she was awarded the Draper Medal of the National Academy of Sciences, and in 1932 the Ellen Richards Prize. In 1914 she was elected an honorary member of the Royal Astronomical Society.

Although much the greater part of Miss Cannon's work consisted in the study of astronomical photographs and in the compilation of her own and other people's results, she was herself a very able observer. She made regular visual observations of variable stars, especially during the early years at Harvard; and many of the photographs used in her investigations were taken by herself. In 1922 she spent six months at the Harvard station at Arequipa, Peru, photographing the spectra of the southern stars with the 10-in. Metcalf telescope. Her work on variable stars alone was very prolific. She was one of the pioneers in the photographic study of stellar variability. She discovered 277 variable stars and 5 new stars, and published several extensive catalogues of variable stars. Perhaps her most important contribution to this branch of astronomy was her compilation of a bibliography of variable stars comprising more than half a million separate cards, which she always kept up to date, and which has been of immeasurable value to all workers in this field.

By far her most important work was the production of the "Henry Draper Catalogue", which in nine volumes of the *Harvard Annals* gives the spectral types and magnitudes of 225,300 stars completely over the whole sky down to about the ninth magnitude. Not only was Miss Cannon responsible for the examination and classification of the spectra and for the preparation of the material for publication, but it was mainly due to her that the system of classification adopted in the catalogue was developed and ultimately defined. The classification was first described by her in 1900, and again, with slight modifications, in 1912; most of the work of classifying the spectra was carried out between 1911 and 1915; the first volume of the catalogue was published in 1918; and the ninth and last volume was published in 1924. It was in 1922 that this same system of classification was adopted by the International Astronomical Union as the official system for the classification of stellar spectra. Since the publication of the main catalogue Miss Cannon had been working on its extension to fainter stars, down to about the 11th magnitude, in the Milky Way and other special regions. She was occupied with this work up to the time of her last illness; and already one volume of the "Extension" had been published.

Miss Cannon did much to further the study of science among women; and in 1933 she founded the Annie J. Cannon Prize to be awarded every few years to some outstanding woman astronomer. But there are other reasons why women of science are indebted to Miss Cannon; for through her lectures, through the example of her own work and enthusiasm, and through the help and encouragement which she so freely bestowed, she was an inspiration to all whom she came across.

Miss Cannon was not only one of the greatest of women astronomers, she was also a woman with a great personality and wide interests, yet withal she was one of the kindest, simplest and happiest of women. She had friends all the world over, among the highest and the humblest, among the oldest and the youngest; and when she was at home surrounded by her work she was never too busy to welcome them. In the death of Annie J. Cannon astronomy has lost one of its most valued workers and countless people a devoted friend.

R. L. WATERFIELD.

Prof. Edmond Leplae

NEWS has just reached Great Britain of the death of Prof. Edmond Leplae, professor of agriculture in the University of Louvain, and director-general at the Belgian Ministry for the Colonies, which took place at Louvain on February 2. He had been staying with his daughter and son-in-law in England not long before the War, but unfortunately returned to Belgium and, when the German invasion occurred, he and his wife fled to France, without being able to reach Great Britain; after the collapse of France they returned to Louvain. It was the second time he had been made homeless by the Germans, but in the War of 1914–18 he had been able to get to Britain and continue his work.

He studied at Louvain, and after making agricultural journeys in North Africa and Brazil, he returned there in 1901 to initiate a course in tropical agriculture. In 1910 the Belgian Government recognized the necessity for developing the agriculture of the Belgian Congo and appointed him director-general. He visited on a study mission the Dutch Indies and the British tropical Empire, and used the experience thus gained in organizing the agriculture of the Congo. It was necessary to provide schemes covering the needs of both Belgian colonists and native cultivators. One of the features which was being watched with interest was the introduction of certain compulsory crops into the native agriculture for the benefit of the native.

Prof. Leplae was one of the leading Continental authorities on tropical agriculture, and his papers issued by the Belgian Ministry include some of the best published on the Belgian Congo. He became favourably known in Great Britain as the result of a report of an agricultural journey in the Congo showing the marked progress that had been made since the Belgian Government had taken over the country in 1908. Native agriculture had been much developed by the extension of rice, oil palm, cotton, rubber and other crops, and although few Belgians had gone out as planters, the living conditions had been so improved as to make possible a considerable extension of plantation industry. A Botanic Garden and Experiment Station had been established at Eala on the equator, and there were other experimental farms in other parts of the country, among them, at Api, a station for the study and the rearing of elephants.

Prof. Leplae's special interests were the conservation of the soil and the development of livestock. He published several important papers on the latter subject and did pioneering work on the conditions necessary for the healthy growth of the animals. The best known is his long report "Organisation et exploitation d'un élevage au Congo Belge", the first edition of which was published in 1926 and the second in 1933; this dealt mainly with cattle; a later report dealt with sheep.

Others of his papers dealt with coffee and with quinine; he early realized the danger of allowing the Congo to become too dependent on the Dutch Indies and advocated a wider culture of cinchona in the Congo.

Leplae will long be remembered both for his contributions to scientific agriculture and for his charming personality. He was an ideal president of an international gathering; at one of the last of these before the War, the Congress of Tropical and Sub-Tropical Agriculture, held at Tripoli in March 1939, he presided with great distinction, and, in spite of the strained situation and the haunting fear at the back of everyone's mind, he carried the meeting through with complete success. He had a perfect command of English, and understood well and deeply sympathized with English ideals without abating in any way his profound affection for his own country.

E. J. RUSSELL.

Dr. R. P. Hobson

BY the death of Dr. R. P. Hobson at Bangor on April 12 at the early age of thirty-nine, agricultural science and biochemistry have lost a very able research worker. Dr. Hobson came to Bangor in 1934 to work on the sheep maggot problem in co-operation with the late Dr. Maldwyn Davies. His previous researches at Rothamsted and the London School of Tropical Medicine fitted him admirably for this work, funds for which were provided by the Agricultural Research Council. His publications dealing with this subject included ten studies (two in the Press) in the *Annals of Applied Biology*, and, in addition, contributions were made to the *Biochemical Journal*, NATURE and *Agriculture*.

The advances Hobson made in these studies are of fundamental importance, and his technique for attracting flies to oviposit on sheep, developed from a study of the chemotropism of the flies and the chemistry of the fleece, has been universally adopted. Workers in Australia, where sheep maggot research has proceeded for much longer and on a much bigger scale than in Great Britain, held Dr. Hobson's work in high esteem, and I know that they will regard their loss as being as great as ours. His more recent work on the effect of suint on sheep dips and the toxicity of calomel to blow-fly eggs is of far-reaching importance. Proposals for developing the ecological side of blow-fly investigations are being examined by the Agricultural Research Council. It was intended that this ecological work should run parallel with Dr. Hobson's researches, and his death at the present juncture is an incalculable loss.

Although not physically strong, Dr. Hobson's health improved after coming to Bangor, and his death after undergoing a major operation came as a great shock to all his friends. His colleagues at the School of Agriculture have suffered a grievous loss, and they offer their deepest sympathy to his widow, who is a member of the same staff. I. THOMAS.

WE regret to announce the following deaths:

Mr. John Crompton, O.B.E., former president of the Textile Institute, Manchester, on May 31, aged seventy-eight years.

Mr. R. L. Hobson, C.B., keeper until 1938 of the Department of Oriental Antiquities and of Ethnography in the British Museum, on June 5, aged sixty-eight.

Admiral Sir Frederick Learmonth, K.B.E., C.B., hydrographer of the Navy during 1919–24, on June 3, aged seventy-five.

NEWS AND VIEWS

The Manchester School of Pure Mathematics

THE Council of the London Mathematical Society has awarded the De Morgan Medal for 1941 to Prof. L. J. Mordell, professor of pure mathematics in the University of Manchester, in recognition of his many important contributions to the theory of numbers. The Adams Prize of the University of Cambridge has been awarded to Dr. H. Davenport, lecturer in mathematics in the University of Manchester, for two essays, (1) "On Waring's Problem", (2) "On the Geometry of Numbers". This double award is a very welcome and well-deserved recognition of the growing of the Manchester school of pure mathematics. Prof. Mordell has been the founder and leader of this school, and Dr. Davenport, formerly his pupil and now his colleague, is the most distinguished of its younger members. He has also attracted a considerable number of foreign mathematicians. His activities have always centred around the theory of numbers, and there is probably no other mathematical school which has contributed so much to the development of that theory during the last ten years.

Aircraft Research Appointments

SIR HENRY TIZARD, rector of the Imperial College of Science and Technology, has been appointed an additional member of the Air Council. In this capacity, and as a member of the Aircraft Supply Council, he will have special responsibility for studying and advising on scientific and technical policy.

Air Vice-Marshal F. J. Linnell, an Assistant Chief of the Air Staff, has been appointed a member of the Aircraft Supply Council in executive charge of research and development. He will be promoted to the acting rank of Air Marshal and will become an additional member of the Air Council on taking up this appointment.

The responsibilities of Sir Frank Smith as the executive head of the Department of the Ministry of Aircraft Production which deals with telecommunications equipment are unaffected by these appointments.

The R.A.F. Food Supplies

THE Air Ministry has appointed Dr. Thomas F. Macrae, a biochemist, and Squadron Leader W. P. Stamm, a specialist medical officer, to watch over the food supplied to the Royal Air Force to ensure that the greatest nutritional value is obtained. Dr. Macrae will investigate foodstuffs in use, and Squadron Leader Stamm will watch for the earliest signs of food deficiency in the health of the men. Both will study the preparation and cooking of food at the various units, the planning of a balanced ration from the available supplies, and the prevention of waste.

The Director-General of Man-Power

MR. G. H. INCE has been appointed by the Minister of Labour and National Service to fill a new post of director-general of man-power. Mr. Ince will take charge of the National Service, Labour Supply, and Military Recruiting Departments of the Ministry. Sir William Beveridge will relinquish the charge of the National Service and Military Recruiting Departments and will act as chairman of a committee, which will also include Sir Charles Craven and Mr. J. C. Little, to examine, in consultation with the three Service Departments, the employment of skilled men in the Forces.

Surgical and Hospital Spirit: Economy Necessary

FOR the good reason that the less the quantity of alcohol absorbed by uses for which alternatives can be substituted the more there will be available for the manufacture of munitions, the authorities are exploring the avenues by which economy in the employment of spirit can be effected. One of the channels through which extremely large quantities of alcohol flow in the course of a year is connected with surgical and hospital practice, and the attention of the Government departments concerned with the conservation of supplies of material is focused on this channel at the present time. It may well be that official instructions will be issued shortly to medical and hospital officers and nursing staffs of Service and other departments to exercise strict economy in the use of spirit for medical and surgical purposes as well as in nursing practice. Action will not stop at the Navy, Army and Air Force Services, for a strong appeal is likely to be made to surgeons and hospital staffs generally to use alcohol as sparingly as possible; it is probable also that recommendations will be issued by a body of recognized experts on the ways in which the use of alcohol may be avoided without prejudice to patients. The sterilization and storing of instruments, the habit common among surgeons of using alcohol for their hands before the gloves are put on, the use of tincture of iodine for the preparation of the patient's skin for operative incisions, the custom of swabbing spirit over the suture line when stitches are removed and the use of methylated spirit for preventing bed sores are the chief outlets of alcohol in surgical work and nursing methods.

There are alternative ways of producing the desired effects efficiently and they will probably be described in an authoritative memorandum. The use of dry heat is an appropriate substitute for spirit for the sterilization of the most important surgical instruments composed solely of steel or glass; if that method is not available, another effective means of sterilizing many types of instruments is by boiling them immediately before use. The risk of blunting the edges of surgical knives through boiling has been proved by recent experiments to be negligible. Where it is impracticable to boil instruments immediately prior to use, they may be stored in a dry state in a covered sterile receptacle instead of in spirit, or, alternatively, in a watery antiseptic solution to which a small amount of borax should be added to prevent rust. Such articles as hypodermic syringes and needles might still be stored in spirit since only a small quantity is needed. If alcohol is used in drying the hands of surgeons it could be applied economically, but adequately, by the use of a spray after the hands have been thoroughly washed and dried with a small sterile towel. Instead of using tincture of iodine for the patient's skin before operation, the area of the operation could be painted with a watery solution of iodine or of one or other of the antiseptic dyes. For swabbing the suture line when stitches are removed after a clean operation, the application of sulphanilamide powder can be recommended in suitable cases, or failing that an antiseptic soap may be used. For treating the backs of bedridden patients an effective method is light massage with zinc oxide and castor oil after the skin has been washed and thoroughly dried; in a small number of clinical conditions, however, the use of spirit for this purpose would be still desirable. More complete instructions will be given, no doubt, when the recommendations are issued.

Electronic Engineering

DURING the past quarter of a century, a prodigious advance has taken place in the development and application of devices utilizing free electrons, either alone or in association with positive ions, including the wide variety of radio valves, gas-filled rectifiers and cathode ray tubes, as used nowadays in communication and electrical engineering. Technical progress in this subject has hitherto been recorded as an important and ever-growing side-line in journals otherwise devoted mainly to radio communication and television, or to electrical engineering in general. As from the June issue, the Hulton Press, Ltd., has incorporated its previous monthly publication entitled *Electronics, Television and Short-Wave World* in a new periodical named *Electronic Engineering*, which is to be of such a scope as to cover the whole field of research and application of electronic devices in general.

The new journal will provide all those engaged in research and industry in this subject with a medium for interchanging ideas and learning the progress which is being made in all parts of the world. Original articles by specialists will appear regularly, and special features will include patent abstracts, reviews of books and instruments and novel circuit arrangements. An important feature, which may be expected to contribute notably to the success of the new periodical, is that Mr. G. Parr, who has been appointed editor, has been closely associated with the electrical and radio industry for more than twenty years. He is the author of a book on the cathode ray tube, and has played an important part in demonstrating the versatility of these tubes as recording and measuring instruments for laboratory and other purposes. The June issue of the journal contains the first of a series of data sheets for the use of design engineers, as well as articles on amplifiers, oscillation generators, quartz crystals and other audio- and radio-frequency problems of current interest.

Cancer and Occupation in Denmark

IN a paper on this subject read before the Danish Medical Society on November 5, 1940 (*Nordisk Med.*, **9**, 869; 1941), Dr. Johannes Clemmesen, of Copenhagen, maintains that cancer research has lost contact with practical medicine and that the etiology of the disease is almost exclusively studied in laboratories, while clinical mass observations are far too uncommon. The following results were obtained by him on examination of the mortality from cancer among males in various occupations in Denmark during the period 1935–1939. In agriculture and similar occupations deaths from cancer in the age-group 45–64 were fewer than would be expected from the average of cancer deaths among the population as a whole. In industry the cancer mortality was higher than the average in accordance with the higher mortality from all causes for this group. After the sixty-fifth year the cancer mortality was the same for all occupations, but the localization varied in the different occupational groups. The cancer mortality among males and females in Denmark showed the following characteristics. In the age-groups 25–44 and 45–64 it was highest among females. In the older age-groups it was highest among males, but this excess for males was highest in Copenhagen, less in the provincial towns and not definite in the rural areas. The total cancer mortality was also highest in the capital, probably owing to the lower mortality from that cause in the agricultural than in the industrial group.

Excavation of Growing Trees with Earth

FOR purely horticultural purposes it is often required to remove trees and shrubs with a ball of earth for transference elsewhere, and considerable care and ingenuity must be exercised if success is to be achieved. Mr. F. A. F. Schmid and Mr. F. J. Nutman, of the East African Agricultural Research Station, Amani, Tanganyika Territory, have described (*Soil Science*, **49**, No. 6; June 1940) a method devised by them during research on the water relations of coffee, for which they required large plants several years in age which could only be obtained in the field. The authors state that by their method a growing tree together with about two tons of soil has been successfully transplanted, and that only the outbreak of war has prevented further excavations. There appears, it is said, to be no limit to the size of the soil block that can be isolated in this fashion save only the size of the vehicle available for transport.

Their work was done in a district with a very light, friable, volcanic ash soil, with few stones. It is admitted that the presence of stones might make this method difficult if not impossible. The apparatus required is simple. The method consists of the preparation, by mechanical means, of an accurately cone-shaped pillar of soil, of a known and definite angle, of the fitting to this pillar of a metal container designed to have the same angle, and of the undercutting and removal of the soil block. Since the container fits the block exactly, and since the lift is *via* the sides, the authors state, of the cone-shaped receptacle, no soil disturbance is possible. The paper, with diagrams, explains the method in full.

Hygiene of the Garden

D. E. GREEN has seized the opportunity of war-time need to survey those plant diseases which are transmitted or aggravated by lack of hygiene in the garden (*J. Roy. Hort. Soc.*, **66**, Parts 1–5, Jan.–May, 1941). This series of papers focuses attention upon the simplest and most economical methods of combating plant maladies, namely, by removing sources of infection and contributory causes. Incomplete removal of diseased material from previously infected crops, the presence of uncontrolled rubbish heaps, the use of contaminated soil for composts, sowing disease-bearing seed, unskilful watering, unbalanced manuring, and even undue handling of the plants by the gardener are all potent factors in the relative incidence of parasitic fungi. The list of diseases which are subject to hygienic control is an impressive one, and includes club root, several root-rots, footrots and damping-off, many virus diseases, leaf spots and rusts; in fact, all diseases should in some measure be subject to this form of control. Mr. Green describes numerous maladies with the help of excellent photographs, and it is difficult to escape the conclusion that phytopathologists and gardeners should direct far more attention to this efficient but unspectacular method of raising healthy plants.

The British Ecological Society

REFERRING to the note in NATURE of May 31, p. 669, on his award of the Linnean Gold Medal, Prof. A. G. Tansley writes: "In the notice of my work which appeared in NATURE of May 31 there is a small error which should, I think, be corrected. It is stated that in 1917 I took over 'the secretary's work and editorship of the Society's *Journal*'. It was not I, but Dr. (now Prof.) E. J. Salisbury, who became secretary of the British Ecological Society in the autumn of 1916, and he held the post until 1932. The guidance of the Society through the critical years of its development was thus shared by the two of us."

The Ray Society

THE annual general meeting of the Ray Society having been omitted for the current year, with the consent of the members, the present officers and council will remain in office, with the exceptions that Dr. E. S. Russell, president of the Linnean Society, has been co-opted as a vice-president and Dr. Stanley Kemp as a member of council. In the annual report, which has just been circulated, the Council states that the accounts show a much more satisfactory state of affairs than might have been anticipated under war conditions. The second volume of Dr. Bristowe's work "The Comity of Spiders" is nearly ready for publication. A volume on "The Larvæ of Decapod Crustacea" by Dr. Robert Gurney is in the printers' hands and will form the issue to subscribers for 1941. The Council will be glad to consider suitable works for early publication. Authors are requested to communicate with the secretary of the Society. The official address of the Society remains "c/o The British Museum (Natural History), Cromwell Road, London, S.W.7", but personal communications for the Secretary should be addressed to Dr. W. T. Calman, "Willowbrae", Tayport, Fife.

Automatic Equipment in Trunk Telephone Working

UNTIL a few years ago, practically all trunk telephone working was done on a delay basis. The principle involved an extravagant method of operating, namely, the segregation of trunk mains into small groups, each of which was controlled by a telephonist. In the Engineering Supplement to the *Siemens Magazine* of March, Mr. H. E. Humphries gives an instructive discussion of the whole subject, laying stress on automatic equipment as an aid to trunk switching. With such an aid, a telephonist can occupy her time fully with other switching duties during a waiting period, and need concern herself with a waiting call only after receiving a signal that a free trunk is available. Remotely controlled automatic switches provide the telephonist with access to a multitude of all trunks. An analysing device in the automatic unit automatically determines which course should be followed. The telephonist leaves the circuit in this waiting condition and proceeds with other work, the supervisory lamp on the trunk side of the connexion giving a fleeting signal every six seconds to remind her that there is a call awaiting completion.

An automatic trunk exchange initially costs more than its manual counterpart, and the natural question arising is whether or not the additional expense of automatic working is a sound investment. Mr. Humphries states that the normal busy-hour load on the Capetown Trunk Exchange demand suite is approximately thirty-six calls per position. This figure is appreciably higher than any equivalent operating procedure could produce on a manual system. Another way of viewing the matter is that an automatic system, with its increased facilities, gives a better and faster service, which is the first necessary step of any administration towards active development of its trunk system.

Meteor Observations in India during 1940

MOHD. A. R. KHAN, of Begumpet, Deccan, who has communicated the results of his observations of meteors for several years to NATURE, has sent an account of his observations during 1940. From this it appears that during the year a total watch of 103¼ hours was maintained on 152 nights and the paths of 1,390 meteors were recorded. The great majority of these belonged to the sporadic class—a result in agreement with that obtained by the Harvard Expedition to Arizona in 1931. The month of December was most prolific, yielding a total of 472 meteors, and on some nights the hourly rate was about forty. An analysis of the magnitudes of the meteors observed is interesting and the table given below will show the relative paucity of very bright meteors. Eight were so faint that no definite magnitude could be assigned to them, and 117 had magnitudes between 4·5 and 5·5. The others were classified as follows:

No.	Mag.	No.	Mag.	No.	Mag.	No.	Mag.
207	4	208	2·5	5	−2·5	6	−4
182	3·5	190	2	6	−3	3	−5
188	3	268	1·5 to −2	1	−3·5	1	−7

Of the bright meteors, 17 were observed after midnight and 5 before midnight, the meteor of mag. −7 being included in the former class. It was observed on March 22d. 15h. 42m. U.T. and gave off a number of sparks during its flight. It is suggested that some of the debris may have fallen to the earth. The usual shower meteors were badly represented, only thirty-six being recorded. Some very bright meteors had low apparent speeds and one in particular is worth mentioning. On Oct. 19 a reddish meteor, mag. 0, took half-a-minute to cover its track of 25°. Another interesting point is that, while meteors of 2·5 to 3 mag. occasionally gave persisting streaks, brighter meteors failed to do so in many cases even when they were appearing to move swiftly. It is suggested that streaks are produced only in certain definite regions of the atmosphere if the meteor has a high geocentric velocity.

Seismological Data from Australia

Valuable data concerning earthquakes during the period October–December 1940 have just been received from the Riverview College Observatory, New South Wales (director, D. J. K. O'Connell, S.J.). During this period sixty-three earthquakes were registered and interpreted, eleven giving a maximum amplitude greater than 2 mm. The greatest amplitudes were on November 27, 1940, when an amplitude of 7·3 mm. was recorded by the north–south component seismograph and 9·0 mm. by the east–west component. This earthquake was felt at Neinduk, at North Baining with intensity 6 on the Rossi-Forel scale, at Kavieng *R.F.* 5 and at Rabaul *R.F.* 4–5. The earthquake of November 22, 1940, which only gave a maximum amplitude of 0·5 mm. at Riverview was felt at Rabaul, New Britain *R.F.* 4, Neinduk *R.F.* 3, Pondo *R.F.* 5 and Kuridui *R.F.* 4. Microseisms prevented the interpretation of some seismograms on which the earthquakes only recorded with small amplitude.

Antonio Pacinotti (1841–1912)

On June 17 occurs the centenary of the birth of the Italian physicist Antonio Pacinotti, who contributed to the early development of the dynamo. Born at Pisa, where his father, Luigi Pacinotti, held the chair of physics, he worked in the physical laboratory of the University, and it was while a youth of eighteen serving in the Garibaldean wars that he pondered over electromagnetic problems. At the age of nineteen he devised an electric generator with a ring armature which he described in *Il Nuovo Ciminto* of May 3, 1865. Though, unlike his contemporaries Jedlik and Hjorth, he did not conceive the possibility of self-excitation, his machine had outstanding results. When twenty-one Pacinotti became assistant astronomer at Florence and afterwards held professorships of physics at Bologna (1864), Cagliari (1873) and Pisa (1882), to which place he returned on his father's death. His achievements were recognized in many ways, and in 1902 the Institution of Electrical Engineers elected him an honorary member. He died at Pisa on March 25, 1912. The seventy-fifth anniversary of his invention was commemorated at Pisa in 1934. A life of Pacinotti has been written by Prof. Polvani, of the University of Milan.

Raymond Vieussens

This year marks the tercentenary of the birth of the celebrated French anatomist Raymond Vieussens; the exact date of his birth is not ascertainable. He was born at a village of the same name in Rouergue, the son of a lieutenant-colonel. He received his medical education at Montpellier, and at the age of thirty became physician to the Hospital of St. Eloys. During the first ten years of his service there he performed five hundred autopsies not only to find out the cause of death but also to discover the normal structure of the brain and spinal cord and follow the nerves from these organs to their insertions. In 1684 he published the results of his investigations in a work entitled "Neurographia Universalis", which contained the most complete description of the brain and spinal cord hitherto given and won him a great reputation throughout Europe. He was elected fellow of the Royal Society in 1688 and a member of the Royal Academy of Sciences in Paris.

In 1685, shortly after being summoned to Paris by Louis XIV to attend the Marquis de Wardes, Vieussens was appointed physician to Madame de Montpensier, cousin to the king, and held that office until her death in 1693 when he returned to Montpellier. In 1705 he published his "Novum vasorum corporis humani systema" which contained a record of several interesting autopsies. In 1715, the year of his death, he brought out a "Traité nouveau de la structure et des causes du mouvement naturel du cœur", which is remarkable for a description of mitral stenosis and of the pulse of aortic incompetence. In addition to his works on the nervous and cardiovascular systems he was the author of an important work on the structure of the ear (1714). He also discovered the fermentative effect of the saliva and the presence of an acid in the blood. Vieussens's name was formerly attached to a number of anatomical structures, but was omitted in the Basle nomenclature introduced in 1895, so that it is no longer familiar to the rising medical generation.

Chlorazol Black *E* as a Vital Dye

THE use of chlorazol black *E* as a stain for general purposes in ordinary microscopical technique was suggested by Prof. H. Graham Cannon in NATURE some years ago[1]. This nearly black substance agrees with many vital dyes in being a sulphonated acid azo-compound; but whereas trypan blue, trypan red, vital new red, diamine fast scarlet, benzopurpurine 4*B*, the various Niagara blues, new Bordeaux *L*, Congo rubine, afridol blue, Baumwoll-rubin, etc., all possess two azo-linkages, chlorazol black *E* has three. It was thought interesting to try the trisazo compound as a vital dye, and the results suggest that it may be a useful one.

A 1 per cent suspension of chlorazol black *E* (No. 581 in the Colour Index) in distilled water may be sterilized by bringing to near boiling-point, cooled, and injected subcutaneously into mice in doses of 1 c.c. Injections may be made every day or nearly every day for a week, and the animal killed the day after the last injection. The dye will have spread locally under the skin and coloured it in the vicinity of the injections, but there will not be that general staining of the skin of the whole of the body which occurs with trypan blue and other disazo dyes. Some slight discoloration of the muzzle may be noticed. The internal organs will be found almost to have retained their ordinary colours. If various organs are fixed in Zenker's fluid, embedded in paraffin and sectioned, it will be seen, however, that the dye has been circulating in the blood; for the elements of the reticulo-endothelial system will have taken it up strongly. Striking preparations may be made by staining chromatin with safranine and cytoplasm with orange *G*, against which combination the black particles of the dye show up sharply. The Kupffer cells in the liver will be found to have their cytoplasm loaded with the dye, while the liver cells themselves are free from any particle of it. No trace can be found in any of the kidney cells and the urine is of the ordinary colour; so the dye is apparently not excreted and one can therefore load the reticulo-endothelial system to capacity. Sections of the subcutaneous tissue in the vicinity of the injections show that the histiocytes and fibrocytes have taken up the dye in large quantities.

The difference between the trisazo and disazo compounds in relation to vital staining cannot be attributed simply to the relative sizes of the molecules, for the disazo compound trypan blue has a molecular weight (961) that is actually considerably greater than that of the trisazo chlorazol black (782). One must suppose that particle size rather than molecular weight is concerned, in accordance with the recent findings of Gordon and Chambers[2] on the penetration of acid dyes into cells.

Chlorazol black seems to combine the selectivity of such vital dyes as isamine blue with the rapidity of action of the disazo compounds, and may therefore merit trial by other workers. The specimen used was from batch number 244541 of the British Drug Houses, Ltd. Dr. H. M. Carleton has kindly examined my slides and given me the benefit of his comments on them.

Parathyroid Glands and Lactation in the Rat

REMOVAL of the thyroid gland together with the associated parathyroid tissue was reported by Nelson and Tobin[1] to have no deleterious effect on lactation, as measured by the growth-rates of litters, in the rat. Contrary results were, however, reported by Folley[2] who, moroever, failed to improve lactation in thyroidectomized rats by injections of thyroxine and small doses of parathyroid extract. Nelson[3] has since confirmed the original findings of Nelson and Tobin. A re-examination of the question in this laboratory, partly in collaboration with Miss H. M. Scott Watson, has reaffirmed the almost total failure of thyroidectomized rats to rear their young and has also shown that administration of much higher doses of parathyroid extract than were previously used results in a significant improvement in lactational performance, which however is still below normal. Typical results are shown in the accompanying table.

Group	No. of rats	No. of pups at 6th day of lactation	No. of pups at 21st day of lactation (weaning)	Mean wt. of pups at 21st day of lactation (gm.)
A	5	38	5	17·4
B	4	30	27	25·6

Group *A*: rats thyroidectomized on 6th day of lactation.

Group *B*: rats thyroidectomized on 6th day of lactation and given daily subcutaneous injections of 10 units of Para-thormone (Lilly) from days 6–9 inclusive and 20 units from days 10–20 inclusive in two cases and from days 10–16 inclusive in the two remaining cases.

These results indicate that the suppression of lactation following removal of the thyroid gland and associated parathyroids is partly due to parathyroid deficiency, a result not altogether surprising in view of the large drainage of calcium from the body during lactation. It must therefore be concluded that the integrity of the parathyroid glands is essential for normal lactation. These experiments are continuing and will be fully reported elsewhere.

I am indebted to Dr. S. K. Kon for generous facilities for working with rats and to Messrs. Eli, Lilly and Co., Ltd., for part of the 'Para-thor-mone' used.

Glycolysis, Hydrolysis and Phosphorolysis in *Corynebacterium diphtheriæ*

THE two culturally distinct types of *Corynebacterium diphtheriæ—gravis* and *mitis*—differ biochemically in that only the former glycolyses glycogen although both glycolyse simpler carbohydrates such as glucose and maltose. On examining the hydrolysing capacity of these bacterial types *in vitro* we found that both gravis and mitis yield cell-free extracts or autolysates which convert glycogen into fermentable reducing sugar. In view of the differential desmolytic behaviour of the living cells towards glycogen it is necessary to conclude that in glycolysis the glycogenase of living cells does not necessarily come into play. It seems probable rather that gravis achieves the degradation of polysaccharide into lactic acid through a reaction path in which hydrolysis takes no part.

The only difference in enzymic outfit between gravis and mitis *in vitro* so far observed by us, is that whereas extracts of gravis contain an active phosphatase, this enzyme is absent in extracts of mitis. It seems natural to connect the difference in glycolytic behaviour with the noted difference in the phosphorylation-dephosphorylation apparatus. Our findings support the theory[1] that the desmolytic degradation of complex carbohydrates *in vivo* by muscle, yeast and bacteria may proceed not through hydrolysis but by a direct attack on the saccharide molecule through phosphorolysis (2–5).

A detailed account of this investigation will be given elsewhere.

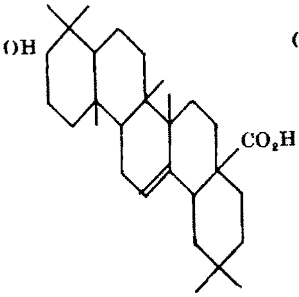
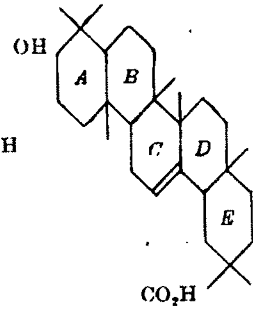
Position of the Carboxyl Group in Oleanolic and Related Acids

MEASUREMENTS recently carried out on monomolecular films of β- and γ-oleananic acids and esters[1] show that these compounds occupy areas very much smaller than those which are calculated on the basis of Haworth's triterpene formula (I), the limiting values for the two acids being 52 and 45 sq. A. respectively. In these two compounds there are no water-attracting groups, apart from the carboxyl group, which could be responsible for the effects observed, as in oleanolic acid itself[2]; the results suggest that the carboxyl group must occupy a position in one of the terminal rings. Of the possible formulations, the structure (II) for oleanolic acid satisfies the principal requirements.



(I)



(II)

The ready formation of lactones from oleanolic and related acids appeared at first to present a difficulty, but examination of models shows that lactonization should be possible with certain stereochemical arrangements of rings *C*, *D* and *E*, and a *cis* or a *trans* fusion of the last two rings. A *cis* fusion of rings *D* and *E* has already been suggested to account for certain reactions of quillaic acid[3].

Effect of Caffeine and Bromide on Dark Adaptation

DURING the past two years we have been making an investigation of dark adaptation of the central region of the retina with special reference to the recovery occurring during the first minute after the end of light adaptation. The work has included some experiments on the effect of doses of potassium bromide and of caffeine on the subject. With doses of potassium bromide up to 25 grains no effect on the rate of adaptation or on the scatter of the observations was observed. With one subject who was used to drinking strong coffee and tea frequently no effect was produced with a dose of 8 grains of caffeine. With another subject whose consumption of tea and coffee may be regarded as at least average, a definite, though rather small, increase in the rate of adaptation was noted when doses of caffeine of up to ten grains were given. The increase was appreciable with 6 grains. In view of these results it is not surprising that at no time were we able to observe any effect due to fatigue or to minor ill-health.

It should perhaps be stated that the effect of a comparatively short period (17 days) of vitamin A starvation was considerably larger than any of the effects observed with the caffeine. The subject returned to nearly the original rate of adaptation as the result of a single large dose of vitamin A (24,000 I.U.).

These results in so far as they refer to fatigue are in agreement with those recently published by Semeonoff[1]. The rather small effects obtained with caffeine may be compared with experiments[2] which appear to show that taking alcohol raises the vitamin A content of the blood considerably.

We wish to express our thanks to the Medical

Research Council of Ireland for a grant in support of this work, and also to Prof. D. S. Torrens for helpful advice.

Infestation of Manufactured Food by Insects

IN summarizing the "Report on a Survey of the Infestation of Grain by Insects"[1], Dr. A. D. Imms[2] has stated that the important result of the survey is the demonstration that the infestation occurs throughout all the industries. In Dr. Imms's opinion the major problems appear to be the regulation of humidity and temperature.

Another side of the problem which is no less important and which has not been dealt with by the Committee is the presence of infestation in manufactured cereal products which are exported from Great Britain to the tropics. It was brought to our notice that a large number of bottles in different consignments of a proprietary invalid food manufactured in England had become infested with beetles.

The food was prepared from malted cereals and wheat flour and the process of preparation was a complicated one in which the article was subjected to heat not exceeding 170° F. and was also subjected to drying *in vacuo*. On examination, the seals of the bottles were apparently intact, although beetles, a large number of them being dead, were noticed inside the bottles. They were two distinct species, *Tribolium castaneum* Linn. and *Sylvanus surinamensis* Linn. The solidification of the food was an inevitable consequence of infestation and in a few samples solidification occurred without the presence of beetles.

With special regard for the manufacturers, we made some experiments with the view of determining if possible how these beetles invade the food. The two main propositions were: (1) if they enter the food in the egg or larval stages before this is put into the bottles; (2) or if they get in afterwards. The former presumption is groundless as a temperature of 125° F. over a period of one hour has been found fatal to eggs, larvæ, pupæ and adults. That it is more probable that the infestation takes place after bottling is supported by the statement made by the local representative that an absolutely fresh consignment is very rarely infested.

It is therefore quite apparent that the beetles get in through the sealing and this is supported by the fact that sometimes the food has been found to solidify without the apparent presence of beetles, which suggests that in these cases there has been connexion with the outside air. In one bottle in which we carefully examined the attachment of the circular disk and waxed paper with a hand-lens, we found the cover loose in two places. This, however, may not have represented careless packing, but the work of the beetles or their larvæ. We therefore suggested the possibility of the beetles, whether larvæ or adults, making a way for themselves through the sealing. With this possibility in view we set up an experiment to see whether larvæ and adults which were previously starved could invade a bottle of the food through a well-sealed cover and we found that they could not or did not. When placed inside a sealed bag made of thin paper without any food, which was then buried in flour dust, the larvæ and adults were not able to eat their way out and died of starvation inside the bag.

The weight of evidence therefore inclines us to the belief that the insect gains ingress to the food through crannies left in the sealing of the covers and not by gnawing a way through for itself.

Regarding the country of origin of infestation, both the species being cosmopolitan, there is no reason why invasion of the food should not take place anywhere either in England, on the sea, or in India. However, as larval and pupal skins were detected in the solidified material and especially on the inside of the waxed paper used for sealing, it is highly probable that the invasion takes place in the larval stage. The smallness of its size and its flattish form allows it to penetrate apparently tightly wrapped packages.

It is indeed surprising that the beetles showed no signs of any attempt to multiply, although both sexes were present. In temperate climates there are normally 4–5 generations a year, but in the tropics the breeding of both the species is continuous.

The matter of using the proper kind of seal is therefore extremely important and sealing wax should be preferred to ordinary wax, the attachment of which is likely to be loose due to shaking on the journey.

"The Physical Condition of the Planets"

READING Sir James Jeans's most interesting and informative lecture at the Royal Institution (see NATURE, May 3, p. 526), one is, I think, brought up short by the following statement "The greater part of both atmospheres [of Jupiter and Saturn] will be at a pressure of more than a million terrestrial atmospheres. Under such pressures, no known substance remains gaseous." This latter statement is so far contrary to what I, in common no doubt with most chemists, have been taught "from my youth up", that I cannot believe it represents Sir James's considered opinion.

If Sir James Jeans really thinks that the general acceptance for the past fifty years of the 'critical temperature' as a definite property of all gases is erroneous, and that the observations of Andrews and of Amagat have been incorrectly interpreted, surely he would have taken some other opportunity than a semi-popular lecture to announce his conclusion to the scientific world.

Another point in Sir James's lecture which appears difficult of acceptance is the postulation of low temperatures in the interiors of these large planets. It is, I think, generally accepted that in a planetary atmosphere in which convection occurs, of which there is ample observational evidence in these cases; the temperature will rise in the layers of increasing pressure in accordance with the known laws of adiabatic compression.

Sir James quotes the observed temperature of the visible cloud surface of Jupiter as −138° C. or 135° K. Published estimates of the ammonia content of the atmosphere above this layer suggest a somewhat higher temperature, as the vapour pressure of ammonia falls to very low values about 145° K.

Assuming the pressure at this level to be one terrestrial atmosphere (it is likely to be much lower) and that the ratio of the specific heats of the gases concerned is only 1·33, the temperature of the part of Jupiter's atmosphere which has a pressure of a million terrestrial atmospheres would be 13,000° K., a temperature probably above the critical temperature of all substances. As a large part of Jupiter's atmosphere presumably consists of helium and the ratio of the specific heats of more complex gases rises quite rapidly with increasing pressure, the average value of this ratio is probably greater than 1·33, in which case the high temperature quoted will be reached at a lower pressure.

The observations of the low temperature of Jupiter's visible surface show that there is no perceptible loss of heat by radiation from matter at high temperatures, so the whole of the mass of the planet within a layer, say, 6,000 miles below the visible surface must be at a temperature of tens of thousands of degrees absolute. If this conclusion is correct, it would make the explanation of the low average density of the larger planets much easier.

JOHN PHELPS.

Royal Mint,
London, E.C.3.

I HAD not meant to express any special views about critical temperature. It is true that the atmospheres of Jupiter and Saturn are above the critical temperatures of some substances, but I imagine critical temperatures become completely unimportant when the pressure is 10,000 or more times the critical pressure; the a/v^2 of Van der Waals becomes insignificant compared with the p, so that the equation of state reduces to $p(v-b)=\alpha T$. Consequently I should expect all substances to behave similarly, whatever their ordinary critical temperatures may be, and in a way which will certainly be very different from that of the usual gas.

In this part of my lecture I was not expressing my own opinions, but describing the conclusions reached (admittedly rather speculatively) by Wildt and H. Jeffreys. These conclusions are based, among other things, on the extent to which Jupiter and Saturn are flattened by their rotation. As I explained in the spoken lecture, this tells us something as to the internal distribution of mass in these planets, although not enough, I think, to rule out Mr. Phelps's suggestion. It would be interesting to see this worked out in detail, although personally I find it hard to reconcile the observational facts (persistence of red spot, etc.) with the possibility of Jupiter's atmosphere being convective down to a pressure of a million atmospheres.

The Rarer Constituents of South African Fireclays

SOME time ago I discussed the occurrence of vanadium and molybdenum in clays[1]. In their comprehensive and often neglected work on the refractory clays of Great Britain, Ennos and Scott[2] reported the presence of various uncommon elements. Vanadium, barium, lithium, manganese, phosphorus, etc., are mentioned. Cobalt, nickel and chromium oxides were reported in traces. Apparently all the work was done chemically.

The following is a résumé of work on two clays and is typical of what is obtained on South African specimens.

Element	Lines examined (A.)	Fireclay from Middelburg, Transvaal	Fireclay, Boksburg
V	3183·42	Distinct	Distinct
	3189·41	Distinct	Distinct
Be	2348·62 3130·56	Very faint	Very faint
Cu	3247·55	Very faint	Nil

Care was taken that impurities in the carbon rods did not vitiate the results. A large automatic quartz spectrograph was used and a great deal of experimenting done to ensure that exposures and current strengths were adequate. In this work barium, tin, etc., were carefully looked for, but were not found. In fact, the ultimate chemical composition of these fireclays is very simple.

Manganese was tested for, both chemically and spectrochemically. Ennos and Scott reported manganese in British fireclays in amounts from a trace to 0·31 per cent MnO. Only in one case was this element noticed in a South African clay, and this was due to local deposition from downward percolating waters which had leached out the manganese oxides from the soils above. Mixed oxides of iron and manganese were deposited along the cracks and joints of the fireclays. However, away from the contaminated zones the same clays did not contain a trace of manganese. It was also noticed that the wet and dry tests for this element were very much more sensitive than spectrochemical ones.

Ennos and Scott reported the presence of chromium in Scottish clays in amounts up to 0·11 per cent Cr_2O_3. This element has so far not been detected in the clays of South Africa.

From the numerous analyses made it is evident that the detection of many of these elements requires special technique. For example, the heavy residues should be separated, and zirconium, barium, chromium, etc., looked for there. The extraction of vanadium and molybdenum after calcination has already been discussed. Spectro-chemical analysis in itself is not sufficient to report the absence of an element. It must be confirmed chemically.

Sulphur and phosphorus have always been found to be present in South African fireclays, by chemical means. Carefully made blanks are absolutely necessary in any work of this kind.

RESEARCH ITEMS

Anthropological Connexions between America and Siberia

A. Hrdlička discussed this connexion at the annual meeting during April 28–29 of the U.S. National Academy of Sciences. Since 1926, under the auspices of the Smithsonian Institution, systematic anthropological researches and excavations have been carried on in Alaska. It was possible in 1939 to supplement the study of the collections, thanks to the Soviet authorities and men of science, with that of approximately 600 crania of various Siberian populations, from the Neolithic times onward. As partly reported to the Academy at its last annual meeting, the Neolithic skulls from the Angara and upper Lena region showed remarkable similarities with the oblong type of skull of the American Indian. It is now possible to supplement this with more evidence. The total is based on approximately 4,000 normal adult crania, the essential metric data on which are now ready for publication. These data show definitely a close affinity between the aboriginal Siberians and Americans. In some instances the relation between a Siberian and an American group is so close as practically to amount to identity; and similarly some of the Old Alaskan resemble certain mainland American groups. The evidence now available makes it possible, in brief, and besides the Neolithics who have already been discussed, to identify the Eskimo with the Chukchi, and the Aleuts with the broader headed type of the Tungus; nor do the resemblances stop there. In addition, the crania of the newly discovered Pre-Aleuts are seen to show a very near resemblance to the Siouan type; those of the similarly newly found Pre-Koniags of the Kodiak Island to the Algonkin type; and those of the Koniags, the people found on Kodiak at the advent of the Russians, with the southern Indian Alaskans. Thus, from the physical point of view, which alone can be reliable in the classification of human groups, America may now be definitely connected with Siberia, and Alaska with the rest of America.

Hormones Capable of Increasing Liver Fat

These hormones were discussed by O. Riddle and D. F. Opdyke on April 29 at the annual meeting of the U.S. National Academy of Sciences. Hormones derived from the ovary, pancreas, adrenal and especially from pituitary glands have been studied with reference to their ability to increase the storage of fat in the livers of young pigeons and rats. Since unlike results were obtained with these two species, this report is restricted to effects produced in pigeon livers following daily treatment during 2–4 days. Neither luteinizing hormone, adrenotrophin, intermedin, nor the inseparable mixture of gonadotrophin and thyrotrophin increases liver fat when those hormones are used in the purest form now available. Prolactin usually, but inconsistently, increases the liver fat in pigeons (not in rats), though it regularly increases the size of hepatic cells in pigeons. Insulin, desoxycorticosterone acetate and œstrone all increase liver fat. Anterior pituitary fractions obtained by ammonium sulphate precipitation, with dialysis of precipitates formed at one-third (and one-half) saturation, have resulted in appreciable concentration of liver fat activity in the water-soluble portion of the precipitate formed at one-third saturation. This fraction contains notable quantities of adrenotrophin, thyrotrophin, gonadotrophin and (traces of) posterior-lobe hormone, but it is almost free from prolactin. The 'pseudoglobulin' fraction (that is, the water-soluble part of the precipitate formed at one-half saturation) obtained in this series (done according to Young, 1939), though contaminated in fairly equal degree with all the hormones listed above for the highly potent fraction (and likewise almost free from prolactin), is practically free of liver fat activity. Pituitary extracts apparently show liver fat activity in all or many species, but it is not probable that this activity is produced by a single substance and not yet proved that an extract which is effective in one species is widely effective in others.

Sex-determination in the Earwig

Forficula auricularia has eleven pairs of autosomes (H. G. Callan, *J. Gen.*, **41**, 349–374; 1941), and there are two types of males: x, Y, and x_1x_2Y, and three types of females: x_1x_1, $x_1x_1x_2$, and $x_1x_1x_2x_2$. In the x_1x_2Y there may be a trivalent or a bivalent and univalent. The Y chromosome is dicentric and aids in the orientation of the trivalent during meiosis but may sometimes fragment and nondisjoin during the spermatogonal mitoses. The Y chromosome may be lost with high frequency. The prevalence of the twenty-five chromosome male x_1x_2Y in a population may have a selective advantage in giving rise to more females than males; in a dense population, one male may be sufficient for many females. The evolution of the sex-determining mechanism in Anisolabis and Forficularia is traced, and the presumed homology of the chromosomes x_1, x_2 and Y is suggested.

Polydactyly in the Fowl

D. C. Warren (*J. Hered.*, **32**, 3–5; 1941) has reported a further case of inherited polydactyly in the fowl. The character has been named duplicate, since in extreme cases the foot and shank are doubled. There is considerable variation in this dominant character, ranging from an appearance similar to that of a normal five-toed race to an almost complete duplication of the foot. Matings between a homozygous dominant and a heterozygous individual gave 2 normals in 144 individuals, indicating that as in the classic type of polydactyly the heterozygous individual may not show the abnormality. From crosses involving duplicate and polydactyly, it is believed that duplicate is an allelomorph of polydactyly.

Hybrids of the Maple

O. M. Freeman has crossed *Acer rubrum*, the red maple, and *A. saccharinum*, the silver maple (*J. Hered.*, **32**, 11–14; 1941). The hybrids were intermediate in rates of growth between the parents and had a dense amount of foliage. The leaves of some of the hybrids have holes in the leaves corresponding in position to the deep sinuses of the leaf of the silver maple. Of fourteen plants which flowered, ten were staminate and four were pistillate. The chromosome number of the red maple may be 36, 54, or 72, whereas the silver maple has 26 chromosomes. Several second generation plants are being raised.

Relative Position of Cell Walls in Developing Plant Tissues

THIS topic was discussed by E. W. Sinnott and R. Bloch on April 28 at the annual meeting of the U.S. National Academy of Sciences. In growing plant tissues the position of new cell walls is not fortuitous but has a definite relation to the position of walls already present in adjacent tissues. There are two main types of relative wall position: (1) Most commonly, a new wall avoids intersecting an old one at a point directly opposite the point of insertion of an adjacent partition wall, so that the walls alternate or 'break joints' and only three meet at a point. This type can best be studied in tissues where the cells are in parallel rows and all new walls are in one plane. In such cases the degree of avoidance can be shown graphically. (2) In certain tissues just the reverse condition occurs, a new wall being formed directly opposite the point of insertion of a previous one, so that four walls meet at a point. This is frequently found in the cortex of roots, in polyderm and in normal and regenerative periderm. Developmental studies show that the factors determining the position of the wall do so very early by controlling the position of the plate of cytoplasmic strands, or phragmosome, long before the wall itself is laid down. For this and other reasons the liquid film hypothesis, commonly invoked to explain the alternating type of wall position, is regarded as inadequate. The opposite type of wall position seems to be related to local changes in the character of the mother-cell wall. Apart from their bearing on the general appearance of plant tissues, these facts are of significance in problems dealing with tissue cohesion, the production of aerenchyma, and the number of faces of contact between cells.

The 'Great Dyke' of Southern Rhodesia

THE mystery of the geological structure of the 'Great Dyke' has been a challenge to geologists ever since 1870, when this immense intrusion was first recognized. A summary of our knowledge of the 'Great Dyke' has been given by B. Lightfoot in a recent presidential address (*Proc. Geol. Soc. S. Africa* for 1940; 1941) in which he suggested that geophysical methods might supply some of the missing information. As a result of this call for specialized research, O. Weiss and his colleagues have carried out gravimetric and earth-magnetic measurements (*Trans. Geol. Soc. S. Africa*, **43**, 143–151; 1941). The gravity anomalies are the largest ever published over similarly narrow widths on any continent, their maximum being 46·7 and 54·0 milligals on the two traverses made. The evidence proves the existence of a heavy, slowly tapering and very deep linear core below the exposed rocks. The core has an average density of about 3·3, and it is considered to be peridotite or possibly pyroxenite. It is suggested that the name 'dyke' is not appropriate and that the term 'abyssolith' would more accurately describe this enormous injection. It is remarkable that over the core of the abyssolith no major magnetic anomaly has been found, indicating that the core contains no appreciable proportion of magnetic minerals. Since magnetite is abundant in the serpentines of southern Africa, including those of the surface exposures of the abyssolith, the evidence supports the conclusion that serpentinization has not affected the core. Weiss suggests that the superficial serpentinization was due to hydration by waters of meteoric origin. It is to be hoped that similar geophysical exploration may be extended to the Bushveld Complex, with a view to the discovery of the location and structure of the feeder or feeders of that still more amazing assemblage of igneous rocks.

Radioactivity of Ocean Sediments

SINCE Joly's early investigation of the radium content of samples of deep-sea deposits from the *Challenger* Collection it has been known that such deposits are extraordinarily rich in radium, the concentration being four to ten times that found in average granite. Later work has shown that there is much less radium in ocean water and much more in the abyssal sediments than is appropriate to the uranium present in the same materials. C. S. Piggot and W. D. Urry have studied core samples of abyssal deposits, several metres long (*Amer. J. Sci.*, Feb. 1941). It is found that the high concentrations of radium are purely superficial and do not extend to any appreciable depth below the ocean bottom. At a point but a few metres down, the radium falls to a value which corresponds to the amount in equilibrium with the uranium present, an amount which is of the same order as that in ordinary sediments. Thus, there is no greater generation of heat by radioactivity over the ocean floor, to blanket the flow of heat from below, than there is in the continental rocks. Evidently there is some mechanism whereby radium, and also its immediate parent ionium, is abstracted from the ocean water, leaving most of the uranium behind. The ionium produces more radium, and the excess of these two elements in the bottom sediments, unsupported by uranium, eventually disappears. Various mechanisms that have been proposed to account for the abstraction—biological, chemical and physical (adsorption or base exchange)—are critically reviewed, and it is shown that while some are inadequate, others, notably the physical, have not yet been given the consideration they deserve. More data are essential before the problem can be solved.

Disintegration of Boron by Slow Neutrons

THE disintegration of boron by slow neutrons has been investigated by R. S. Wilson (*Proc. Roy. Soc.*, A, **177**, 382; 1941) using an ionization chamber filled with boron trichloride in conjunction with a linear amplifier. Evidence is found for two disintegration energies. Assuming that the greater energy release corresponds to the formation of the ^{7}Li nucleus in the ground state and is therefore 2·99 Mev., then the smaller energy, which is released in about 93–94 per cent of the disintegrations, and is 2·57 ± 0·05 Mev. An explanation is offered of the contradiction with the results of Maurer and Fisk. The γ-radiation associated with the reaction has been detected, and a rough measurement of its quantum energy has been made.

Magnet for Cosmic-Ray Cloud-Chamber Studies

THE design and characteristics of a magnet for cosmic-ray cloud-chamber studies were described by R. B. Brode on April 28 at the annual meeting of the U.S. National Academy of Sciences. The study of cosmic-ray mesotrons requires a magnet that will appreciably deflect particles of an energy of 10^{10} electron-volts. The operation of a Wilson cloud-chamber requires long periods of operation at constant temperature. The design and dimensions of a magnet for this purpose were determined by studies on small models. In the final magnet 5,300 pounds of steel were used in casting the yokes and 2,700 pounds of copper wire were used in the coils. To reduce the saturation in the steel, the poles were coned from a diameter of 18 in. to a diameter of 12 in. in ten inches distance. The front pole has a conical hole in it that permits the cloud-chamber to be photographed directly without the use of mirrors. The hollow centre of the front pole throws flux from the centre towards the outside so that the flux-density as measured in the illuminated plane of a cloud-chamber 30 cm. in diameter is constant to within 5 per cent. The coils were wound with No. 6 square double-glass-covered copper wire. The turns were cemented together with an air-drying binder. Cooling is provided by the circulation of water in four layers of copper tubing in each coil. Six kilowatts obtained from the direct-current supply system produced an average field of over 9,000 gauss. In spite of the large hole in the front pole the equivalent air-gap of the magnet is only 14 cm.

Experiments with Mesotrons in a Large Wilson Chamber

STUDIES bearing upon the production and disappearance of mesotrons have been made by R. P. Shutt and T. H. Johnson in a large Wilson chamber containing three lead plates. These were described by the latter on April 28 at the annual meeting of the U.S. National Academy of Sciences. Since the observational data consist of the directions and the densities of the tracks before and after the traversals, whereas the processes of interest occur within the lead plates and are not observed directly, the method is essentially statistical. A pair of mesons, originating in a lead plate with no visible particle entering above, would be evidence of the production of mesons by gamma rays, but no events of this nature have been observed although many would have been expected if the hypothesis were tenable that gamma rays in the upper atmosphere are the principal producers of mesons. The ratio of the number of slow mesons with dense tracks in the gas to the number stopped by the lead plates agrees with expectations based upon the ionization losses and gives no indication of other absorptive processes. The scattering of the mesons by the lead is also that predicted for the coulomb forces, and gives no indication of extraordinary forces acting between mesons and lead nuclei. If mesons are being stopped by processes other than ionization, the statistics obtained from 10;000 tracks traversing the lead are insufficient to put such processes in evidence, and it will be necessary to adopt a technique in which the individual events are observed directly in a dense gas. For this purpose the authors are constructing a cloud chamber 12 in. in diameter to operate at a pressure of 200–300 atmospheres. This chamber will be immersed in a transparent oil contained in a thick-walled steel tank. Photographs will be made through a thick glass window the size of the camera lens, and the chamber will be illuminated by arcs placed inside the tank. When filled with argon this chamber will have a cosmic-ray stopping power equivalent to 7 cm. of water or nearly 1 cm. of lead.

Phosphoryl Bromide

THIS compound, $POBr_3$, has previously been obtained with difficulty, some of the reactions leading to explosions. C. R. Johnson and L. G. Nunn (*J. Amer. Chem. Soc.*, **63**, 141; 1941) have found that phosphorus tribromide vapour may be oxidized rapidly yet non-explosively to the oxybromide by gaseous oxygen in the presence of nitric oxide. It is concluded that the oxidation is catalysed by N_2O_4 and not by NO_2. The effect of various factors on the velocity of the oxidation was studied but the paper omits to give any practical details for the isolation of the phosphoryl bromide.

Gratings and Replicas for Astrophysical Research

AN account of the improvements made in reflecting gratings which have resulted in their adoption in place of prisms in the large spectrograph of the 100-in. telescope on Mt. Wilson and elsewhere was given by R. W. Wood on April 28, at the annual meeting of the U.S. National Academy of Sciences. Batteries of large replica gratings have been made and tested on the 18-in. K. Schmidt star camera on Mt. Palomar with excellent results, and 18-in. disks of glass are now in preparation which will carry elementary gratings 4 in. × 6 in., covering the entire aperture of the instrument. Excellent photographs of the spectrum of Arcturus were obtained in ·10 seconds with a replica having 7,500 lines to the inch, covering a Schmidt camera of 3-in. aperture and 5-in. focus, and one of the ring nebulæ in Lyra in 10 minutes. A new combination of two gratings and two prisms, covering the objective of a telescope, gives two spectra of each star, in coincidence, one above the other, and displaced in opposite directions by Doppler shift due to stellar velocities. Gratings of both types have been made giving as high as 85 per cent of the light in a single spectrum.

Reddening of Stars near the North Pole

THE scale of normal colours of the stars is based on observations of the stars in the North Polar Sequence. It is unfortunate but not irremediable that when these stars were selected as standards it was not known that interstellar absorption near the pole appreciably reddened their light. The 1938 report of the International Astronomical Union estimated this reddening to amount to 0·10 mag. A paper by Keenan and Babcock, however (*Astrophys. J.*, **93**, 64; 1941), suggests that at least part of the reddening is only apparent: that it is not due to absorption, but occurs because the polar standards have been classified from 1 to 2 spectral subdivisions too early. They reclassify on spectrograms taken specially for the purpose 75 stars in the polar cap, and compare their photo-electric colours with those of 37 bright stars of such high galactic latitude that they can be regarded as unreddened. The colour excesses thus found can best be represented by assuming that absorption does not set in until a distance of about 200 parsecs is reached, the reddening then increasing to 0·04 mag. at 400 parsecs. Nevertheless, the data do not preclude the possibility of an absorption coefficient increasing linearly with distance. Whichever interpretation is finally accepted, however, the paper makes available for future research a valuable list of polar standard stars the deviations of which from normal colour are now accurately known.

THE ACCRA EARTHQUAKE OF JUNE 22, 1939

THIS earthquake, which caused the deaths of seventeen people and injury to upwards of 135 others, besides doing damage to buildings to the extent of hundreds of thousands of pounds in Accra, the capital of the Gold Coast and the surrounding country (NATURE, 144, 18; 1939), has recently been the subject of comprehensive research*. The Gold Coast as a whole is a relatively stable region and earthquakes are rare, though the Accra district and the coastal area to the east and west are subject to earthquakes. Major shocks occurred in 1862, when every stone building in Accra was razed to the ground and Christiansborg Castle and the forts at Accra taken over by the British from the Danes twelve years before, were rendered uninhabitable; in 1906 when on November 20 Government buildings in Accra were damaged though no casualties were reported; and in the present instance. Recorded minor shocks occurred in 1636, 1858, 1863, 1883, 1907, 1911, 1918–19, 1923, 1925, 1930 and 1933–35.

There are no records of any minor precursor shocks to the 1939 earthquake since the operation of the seismograph at Accra had been discontinued a few years previously on the grounds of economy; but between 1932 and 1935 cracks began to appear in substantial Government buildings in Accra and in the ground near the buildings. At the time Dr. Junner directed attention to the possibility of earthquakes occurring within the next 10–15 years. The earthquake of June 22, 1939, occurred at approximately 7.20 p.m. (G.M.T.) and was felt for about 20–30 seconds at Accra. There is no doubt that casualties were fewer than might have been expected from the severity of the shock since at the time many people were out of doors and there were no subsequent outbreaks of fire. The earthquake was felt by persons over an area of approximately 300,000 square miles and at places more than five hundred miles from Accra. As the epicentre was probably out to sea some twenty-five miles from Accra it is likely that it would have been felt over an area of 600,000 square miles if the whole of the area had been populated land.

According to a geological and engineering survey conducted immediately after the shock and a study of the answers to a questionnaire circulated in the area, it appears that the maximum intensity reached on the modified Mercalli scale was 9 (probably 10 at the epicentre). Accra experienced intensity 8. The villages within isoseismal 9 consisted almost entirely of swish buildings or of grass huts. In Aplaku, situated on Akwapimian quartzite near the Sakumo lagoon, ten houses were razed to the ground and most of the others lost walls facing north-west or south-east. Nyanyanu, similarly situated, was almost completely ruined, and in addition the north-west sides of all the cylindrical fish-drying kilns in the village were forced out. The small villages of Amanfro, Tokuse and Tetegbu, situated on alluvium, suffered much damage. A line of fissures in alluvium and earth with, in places, a downthrow to the south-east of 9–16 in. stretched from Fete to Weija, and another series of fissures was formed in the sand on the sand spit south of Sakumo lagoon. Near Tokuse the fissures were, in places, up to 15 ft. wide. Villages on the north-western side of the fissure were only slightly damaged while those on the south-east side of it were ruined. Small cracks also occurred in several places in made-up ground and rarely in weathered Akwapimian quartzite. Scores of vents and fissures from which water, sand and mud poured for several hours occurred along the western and southern sides of the Sakumo lagoon. The water works at Weija (intensity 8) were seriously damaged.

At Accra during the earthquake a loud and sustained rumbling was heard and some found it difficult to walk. The sea is said to have become rough and fishermen at Labadi and Teshi say their canoes shivered and that they lost control for a time. The earthquake was just short of world shaking according to the evidence of seismographs. As a result of the examination of the seismograms obtained at about sixty observatories throughout the world where the shock was recorded, a least squares solution using the P waves alone gave:

Initial time = 19h. 19m. 25·8s. ± 1·0s. G.M.T.
Latitude = 5·18° N. ± 0·03°
Longitude = 0·13° W. ± 0·03°
Depth of focus = 13 km. ± 2 km.,

probable errors being given. These results were checked by statistical methods, by readings of other pulses, and by the macroseismic evidence. The energy of the earthquake was of the order of 10^{19} ergs. From June 22, 1939, until July 11, 1940, ninety-four aftershocks have been recorded, these showing a distinct diminution in frequency as time progressed, with the possible exception of February 12, 1940, when eight occurred.

In view of the seismic history of the district, the geological evidence concerning the 1939 earthquake and the engineering aspects of the earthquake, which showed that failures in structures were often due to poor materials, poor construction or poor design, certain recommendations have been made for the rebuilding of Accra. It has been suggested that Government headquarters should be transferred to a more central and more suitable site than Accra. The advantages of such a transfer would probably outweigh the disadvantages except that the initial cost would be very great. If it is impracticable to move from Accra it is of the greatest importance that rebuilding and future building should be, so far as is possible, on sites favourable from the geological point of view to withstand earthquake shocks, and that buildings and other structures should be designed and constructed in such a way that the effects of earthquake shocks will be reduced to a minimum. It should not be necessary, however, to build special earthquake-proof structures except for large buildings on unfavourable sites, and for essential public works such as reservoirs and power stations. From the geological point of view the area east and north-east of a line from Christiansborg police station to Okplonglo is considered to be the most suitable for rebuilding and future building programmes. Stricter control and supervision of the design and construction of all buildings other than single-story, inferior-type buildings is advocated, and the following facts, together with others, based largely on the experience gained in regions subject to severe earthquakes, should be taken into account when permanent rebuilding at Accra is being considered:

---

* Gold Coast Geological Survey Bulletin 13: 'The Accra Earthquake of 22nd June 1939'. By Dr. N. R. Junner and other authors. Pp. 67. (Accra: Geological Survey; London: Crown Agents for the Colonies, 1941.) 3s.

(*a*) A building should be of simple design and should be so constructed that it will move as a whole in an earthquake.

(*b*) Buildings should be as nearly square and as low as is conveniently possible.

(*c*) Foundations should be strong and deep.

(*d*) All unnecessary ornamental work should be avoided.

(*e*) Walls should be light and strong. Arches and windows are a source of weakness.

(*f*) Roofs should be light and rigid and should not be steeply inclined.

(*g*) Piers may be a great source of weakness. Arched piers should not be used, and all piers should be constructed to withstand an acceleration of at least 3 ft. per second from any direction; in other words, the width at the base of the pier should be at least one tenth of the height of the pier. Tapered piers are advisable in seismic areas and stronger cement may be used near the base of a pier.

(*h*) Well-constructed wooden buildings will oscillate greatly but will withstand anything but very severe earthquakes unless the structures are built on unconsolidated materials.

(*i*) Good-quality building materials and workmanship are essential.

(*j*) Inferior-quality buildings should not be of more than one story.

RECENT RESEARCHES ON RUBBER

RUBBER FRACTIONS

PUBLICATIONS Nos. 3–6 of the British Rubber Producers' Research Association follow a well-beaten track with interesting new details. On the general principle that rubber is a mixture of molecules of different lengths, several previous investigations have attempted to sort the molecules out either by fractional precipitation from solution or by fractional dissolution. A division into 'sol' and 'gel' rubber on these lines has become more or less standard. G. F. Bloomfield and E. H. Farmer (*Inst. Rubber Ind. Trans.*, **16**, 69; 1940) have adopted fractional extraction as their mode of approach, using mixtures of petroleum ether and acetone as extractant, differentiating the fractions in relation to the increasing proportion of petrol in the extracting mixture. Oxygen was rigidly excluded at all stages, but it may have been unfortunate to add β-phenylnaphthylamine to the extraction mass; this compound is an anti-oxidant for vulcanized rubber, but may act in some conditions as an oxidation promoter for raw rubber.

Four distinctive fractions were taken at arbitrary points—a first small one containing appreciable combined oxygen; a second fraction comprising a pure hydrocarbon of relatively low molecular weight; a third, also pure hydrocarbon, of higher molecular weight; and a fourth containing appreciable combined nitrogen. There was also an insoluble residue. Different types of raw rubber gave different proportions of extract, and at various compositions of the mixed solvent, so that there is little that can be said of a conclusive nature about the make-up of rubber in relation to this extractant.

However, G. Gee and L. R. G. Treloar (*Inst. Rubber Ind. Trans.*, **16**, 184; 1940) have examined several properties of some of these fractions with results of considerable interest. Using methods previously described (Gee, *Trans. Faraday Soc.*, **36**, 1162, 1171; 1940), the molecular weights of the four fractions, in a particular case and from viscosity data, were found as 63,000, 240,000, 350,000 and 360,000. Experimental technique is not yet available to decide whether these, or some of them, represent well-defined classes of uniform length molecules, or merely average 'cuts' in a continuous range of molecular lengths. Several of the properties measured varied in a systematic way with the molecular weight, as for example, the plastic flow, tensile behaviour, crystallization phenomena, and extensibility range. Properties independent of molecular weight seem to be the temperature at which retraction occurs after extension to produce crystallization, and the low-temperature elastic limit. It is particularly interesting to observe that the physical properties of the third fraction are remarkably similar to those of normal crêpe rubber, indicating clearly that the usual elastic properties of (raw) rubber are not dependent on the presence of either low-molecular constituents or 'gel-skeletons'.

PROTEINS IN HEVEA LATEX

Publication No. 2 of the British Rubber Producers' Research Association brings out a marked resemblance between rubber latex protein and typical leaf proteins. The following table, from G. R. Tristram (*Biochem J.*, **34**, 301; 1940), compares his analyses with leaf protein analyses by Chibnall:

	Amino-acids as percentage protein	
	Latex	Various leaves
Ammonia	1·46	0·97– 1·17
Arginine	6·90	7·1 – 8·2
Lysine	5·68	4·6 – 6·2
Histidine	0·63	1·0 – 1·6
Glutamic acid	13·68	11·4 –14·0
Aspartic acid	10·5	7·9 – 8·8
Tyrosine	7·24	4·8 – 6·1
Tryptophan	1·49	2·1 – 2·4
Methionine	1·12	2·2 – 2·7
Cystine	1·02	1·4 – 2·2
% Total nitrogen	14·95	12·8 –15·0

The similarity in the two sets of figures undoubtedly suggests some relationship between the proteins in the leaves and latex of *Hevea brasiliensis*, and the question is being pursued by way of analyses of proteins from Hevea leaves themselves.

J. McGavack and C. E. Rhines (*Ind. Eng. Chem.*, **32**, 1072; 1940) recently showed that the nitrogen content of "whole latex" is approximately constant at 0·25 per cent, the analyses being of 117 samples, collected in a single month (thus avoiding seasonal variation) from many types of tree. There is a suggestion in this constancy that the tree produces some nitrogenous compound to an optimum concentration, either as an auxiliary to the synthesis of caoutchouc or as a side product of that synthesis. Tristram's results thus throw an interesting light on such a suggestion, indicating the place of these reactions as in the Hevea leaves, a natural site for photosynthetic transformations. Further results in this field will be awaited with impatience.

THE 200-IN. TELESCOPE

THE twelfth Thomas Young Oration was delivered before a meeting of the Physical Society by Dr. H. Spencer Jones, Astronomer Royal, on May 30. He described some features of the 200-in. telescope now being constructed for the California Institute of Technology.

This telescope was made possible by a grant of six million dollars from the Rockefeller General Education Board. The design and construction of a telescope of double the aperture of the largest telescope previously built required careful consideration of a large number of problems. The primary problem was the construction of a 200-in. mirror. If made, in accordance with previous practice, of a solid block of plate glass, annealing for nine years would have been required. Mirrors of stainless steel or of metal coated with glass of the same coefficient of expansion were considered but were regarded as too experimental; fused quartz with a surface coating of clear quartz was tried but abandoned, not because the difficulties were insuperable but because the cost would have been too great. A special pyrex glass of high silica content, with a coefficient of expansion only three times that of quartz, was finally decided upon. The disk was cast, by a special technique evolved after much experimental work by the Corning Glass Company, with a ribbed honeycomb structure at the back to reduce the weight without sacrifice of rigidity. Annealing for ten months proved to be adequate for this special glass. The disk weighs 14½ tons and its optical figuring is well advanced.

The mounting embodies many new features. It is of a modified yoke type, the upper bearing being in the form of a giant horseshoe, 46 ft. in diameter, within the throat of which the telescope can lie for observations at the north pole of the sky. Only one machine in the world was large enough to machine this bearing. The yoke arms are hollow cylinders, 10 ft. in diameter, joined by a bent box girder 46 ft. long, which carries the hemispherical thrust bearing, 7 ft. in diameter. An oil pad flotation system enables the 450 tons of the moving parts to be turned with a torque of only 50 lb.-ft. The primary focus is at $f/3 \cdot 3$ and the observer makes his observations within a 6-ft. diameter cylinder, supported from the upper cage of the tube. The Cassegrain focus is at $f/16$ and observations can be made either at a focus just below the central hole of the 200-in. mirror, where there is a platform for the observer, or, by the interposition of a diagonal flat mirror, within either of the hollow yoke arms. The Coudé focus is at $f/30$, and observations with high dispersion spectrographs can be made within a constant-temperature room just south of the telescope. At the primary focus, coma would be serious at a small angular distance from the axis; two special correcting lenses of zero power have been designed to eliminate coma. For observations of faint objects, with low-dispersion spectrographs, two special short-focus camera objectives of great relative aperture have been constructed; one of these, with relative aperture of $f/0 \cdot 35$, on the principle of the oil-immersion microscope objective, is of British design and construction. The ingenious image-slicer, designed by Dr. Bowen, will give a greatly increased efficiency in all spectrographic observations.

All auxiliary mirrors are permanently carried on the mounting and can be operated by remote control. The telescope drive is of an elaborate nature; the effects of changing refraction, of differential flexure and of errors in the gears are automatically allowed for by a system of 'computers'. A quartz-crystal oscillator provides the fundamental control of the rate of drive. A complicated system of Selsyn or interlock motors enables the telescope to be set rapidly to any predetermined position, the position of the dome and of the windscreen being automatically adjusted.

WIRED RADIO BROADCASTING

WIRED broadcasting has already appeared in service in Europe and other parts of the world. An article written by N. Shinohara and Y. Hirano, of the Ministry of Communications, Tokyo, in the January issue of the *Nippon Electrical Communication Journal*, a summary form in English of the journal of the Institute of Electrical Communication Engineers of Japan, discusses the subject, stress being laid on experiments and the basis of network design.

In one method, a wireless radio receiving and wired radio transmitting station is located at a position near a crowded area of listeners or in a suburban district, where there is little electrical disturbance. The programme received at this station is converted to audio-frequency and sent over special lines to the listeners. This method is known in Japan as an ordinary form of common broadcast reception. The programme is distributed at a fairly high level of volume, so that it is only necessary for the listener to instal a loudspeaker. The resulting low cost of the receiving apparatus is an advantage. The disadvantages, however, accompanying radio-broadcasting cannot be avoided, because this method has an intermediate wireless system. Also a large expenditure of money and materials is needed for the installation of special lines to listeners.

A second method makes use of telephone lines, to which the broadcast programme is supplied at audio-frequency. While this method greatly increases the efficiency of utilization of the telephone lines, the programme is subject to interruption by telephone calls, and it is found that a high level of broadcasting power, such as is used in the first method, cannot be transmitted directly through the lines.

A third method makes use of telephone lines, or lighting and power distribution lines, on which the programme is superimposed by means of a high-frequency carrier wave. In Japan this method has been adopted as the basic principle on which a wired broadcasting network may be established. While the percentage of telephone installations in Japan is low, the percentage of electric lighting is very high, being about 90 per cent, which is second to Switzerland's 99 per cent. The use of lighting and power lines together with telephone lines, therefore, would make it possible to develop an almost complete country-wide network.

Experiments on wired broadcasting in Japan have been going on since 1926 in the form of a carrier system over power and lighting lines. In 1935, broadcasting on high-frequency carriers was proposed by the Ministry of Communications. It is interesting to note that when wired broadcasting on high frequencies was introduced, the aims stressed were the relieving of the congestion in allotted wave bands due to the development of broadcasting, and the distribution of clear, stable, high-quality programmes. In the present crisis, the mission of wire broadcasting has been extended to the important tasks of protecting broadcasts from outside interception and preventing false broadcasts.

In surveying the possibilities in Japan of telephone lines as circuits for wired broadcasting it is found that the number of telephones per 100 persons is 3·80 in cities having populations of 50,000 or more, and 0·84 in towns of smaller population; hence the reception of broadcasts over telephone subscribers' lines is effective only in cities having a high percentage of subscribers. The use of telephone lines is especially necessary in cities where power cables are employed for supplying electricity. Thus telephone lines ought to be utilized as much as possible in the busiest sections of a city and in districts where power cables are used, whereas overhead power and lighting lines ought to be used in the suburbs, in towns and villages, and in cities having overhead power distribution lines. It was considered best to standardize the carrier frequency at 130 kilocycles. This value would be the frequency for the distribution of wired broadcasts to listeners all over the country.

FORTHCOMING EVENTS

[*Meetings marked with an asterisk are open to the public.*]

Tuesday, June 17

INSTITUTE OF PHYSICS (London and Home Counties' Branch) (in the Lecture Hall of Messrs. Kodak, Ltd., Harrow), at 6 p.m.—Dr. D. A. Spencer: "The Applications of Photography in Engineering".

Wednesday, June 18

BIRKBECK COLLEGE (Bream's Buildings, Chancery Lane, London, E.C.4), at 6 p.m.—Foundation Oration by His Grace the Lord Archbishop of York: "Education and Peace".

Thursday, June 19

CHADWICK PUBLIC LECTURE (at the Chelsea Physic Garden, Swan Walk, London, S.W.3), at 4 p.m.—Dr. J. Ramsbottom: "The Inter-relation of Man and Fungus in Health and Disease".*

ASSOCIATION OF SCIENTIFIC WORKERS (Birmingham Branch) (at the University, Birmingham), at 7 p.m.—Prof. J. D. Bernal, F.R.S.: "Science and Society".*

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

HEAD OF THE ELECTRICAL SECTION of the Engineering Department of the Oldham Municipal Technical College—The Director of Education, Education Offices, Oldham (June 20).

BOROUGH ELECTRICAL ENGINEER—The Town Clerk, Town Hall, Woolwich, London, S.E.18 (June 21).

LECTURER IN GENERAL SCIENCE including BIOLOGY and GARDENING—The Principal, St. John's Training College, York (June 23).

DEPUTY BOROUGH ENGINEER AND SURVEYOR—The Borough Engineer and Surveyor, Town Hall, Barking, Essex (June 24).

PRINCIPAL OF THE CAMBRIDGESHIRE TECHNICAL SCHOOL—The Education Secretary, Cambridgeshire Education Committee, Shire Hall, Cambridge (June 24).

LECTURER IN THE MECHANICAL AND CIVIL ENGINEERING DEPARTMENT—The Secretary, Technical College, Sunderland (June 28).

ASSISTANT TO THE ENGINEER-IN-CHIEF—The General Manager and Secretary, Mersey Docks and Harbour Board, Dock Office, Liverpool (June 30).

PROPAGANDA IN EUROPE

IN the recent debates in Parliament, with their striking vindication of parliamentary institutions, and in particular of the value of the House of Commons as a direct supervisor of departmental activities, there have been two main points of criticism or concern. The first of these, the question of man-power and production, has already been discussed in these columns. The second, that of propaganda and the work of the Ministry of Information, including the British Broadcasting Corporation, acquires greater importance with the abandonment by Allied troops of their remaining foothold on the mainland of Europe, no less than with the latest agreement of the Vichy Government with Germany.

Much has been heard in the last seven months of the 'New Order' which Germany will introduce, or is introducing, in Europe. That design for a new economic order is becoming clearer and its features have been admirably outlined in recent publications*. There can be no question as to the urgency of meeting that challenge now in the diplomatic field as well as in that of arms, of exposing the real nature of the German 'New Order' and of expounding the alternative which we have to offer. To allow that challenge to go by default and to fail to refute emphatically and authoritatively the insinuation that we stand for the old order or disorder, and that our only aim is to restore the *status quo* in Europe and to maintain it at home, may do irreparable harm to our cause, both in Europe and overseas.

The publications already mentioned afford invaluable equipment for at least a part of that task. Mr. Duncan Wilson shows clearly how the new order has already meant the wholesale robbery of occupied Europe for the benefit of Nazi Germany, even to the point of actual starvation, and the forced mobilization of labour for Nazi war purposes. The scheme is to be forced on the world by ruthless war, for the exploitation of industry, capital and man-power from one end of Europe to the other, solely to increase the wealth and to strengthen the arms of the Nazis. The 'New Order' is only the old order of exploitation, successively manifested in Germany, the Balkans and the occupied territories of Western Europe since 1933.

Mr. Wilson, however, does not leave it at that. He points out how carefully this 'New Order' propaganda campaign, since Germany gained control of Western Europe in June 1940, is timed to fit in with a strategic plan. The Germans are playing skilfully on the general desire in Europe and America for economic stability, which they promise the 'New Order' will achieve. They do not mention the price of complete political subjugation to be paid by its victims in Europe, or the dominating position it would give to Germany in the markets of the world. They carefully conceal its weaknesses—the reaction in Germany and the occupied territories, and the strain which resistance is already placing on German administration, so that it is already fair to conclude that Hitler can no more bring peace to Europe than he cares to bring it freedom.

The Royal Institute of International Affairs fully corroborates, with its detailed analysis, Mr. Wilson's conclusions. Its careful examination of the German long-term plan for an economic new order in Europe and of the probable effects of its application with reference to the central trends and problems of European economy and the place of that economy in the world as a whole, is searching and authoritative, and is substantiated by an account of the German exploitation of the occupied countries which leaves no room for doubt as to the real nature of the oppression masquerading under the name 'New Order'.

The evidence thus assembled shows clearly that the German policy is to incorporate in the Reich, or, where this is not expedient, to buy up, all the main manufacturing capacity of the Continent, and to trade on terms which may be pushed far in her own favour, with the purely complementary and raw-material producing countries outside her new boundaries. This policy involves the growing impoverishment of the rest of the Continent and the permanent exploitation of 70 per cent of the population of continental Europe, excluding Russia. Moreover, this policy is only part of a scheme for world domination. It appears to envisage putting Africa under the same subjugation, and its attitude to the western hemisphere is clearly that the new Europe is to be independent of the western hemisphere, trading on Germany's own terms purely as a means of raising standards of living above the necessary minimum.

"Europe under Hitler" shows clearly enough how the American peoples would suffer from this system, which would be no better for the outside world than for Europe. Fortunately, it has already been made plain that the United States are fully alive to the implications of such a permanent organization of 325 million people for the support of a war machine having at its disposal material resources almost as great as their own, and headed by men prepared to use it ruthlessly for any purpose which their ambition may suggest. It is by no means clear, however, that the British Government is alive to all the implications arising out of the facts and position disclosed in these analyses.

In the first place, it is of the utmost importance that we should expose to the utmost of our power the weaknesses and the fallacies of the German plan for Europe. Our propaganda must be as widespread and effective as the Nazis', exposing its falsehoods and encouraging the resistance in the occupied territories, which are already taxing Nazi strength and thwarting its purpose. Recent uneasiness about the Ministry of Information and British broadcasting has largely been due to doubts as to whether such propaganda is being carried out on a wide enough basis, and with sufficient purpose and skill to achieve its objective. There is insufficient evidence that it has been given its proper place in our war strategy and directed and executed with the vigour and enthusiasm essential to success.

The second point concerns the elaboration of British proposals for a new Europe. It would be most unwise to concentrate exclusively on exposing the negative sides of the German plan for Europe, glaring as they are. It would not even be an effective reply to his propaganda about our own exploitation of Europe and pretence that he is liberating Europe from the economic tyranny of Britain. Nor can we assume that liberating Europe from Nazi domination means reversing the whole process of economic integration which has been set in motion. We need a more unified Europe, but must attain it by other methods and for other purposes than those of the Nazis. The new order in Europe must seek to create new ties, not to dissolve old ones; to build up, not to destroy.

This is the truth which lies behind projects like the United States of Europe or Federal Union; the practical issue at the moment, however, is not the discussion of legal forms but the consideration of the fundamental issues of European order, the problem of combining individual liberty with the authority essential for social cohesion. Without some measure of pooled resources and central control, European civilization cannot survive, and that concentration can only be achieved by the creation of common loyalties and by a sense of common values.

This has already been recognized by the small nations, as was shown by the acting Norwegian Minister for Foreign Affairs, Mr. Trygve Lie, in a recent broadcast from London to the Norwegian people. Mr. Lie recognized that the alternative to the tyranny of the Nazi 'New Order' is co-operation with the free peoples, and his courageous and heartening words indicate that this co-operation is not limited in Norwegian eyes to the immediate purpose of victory and liberation; but implies "a state which must and shall endure after the war".

Such a declaration implies further responsibilities for Great Britain. The abandonment of a policy of isolation and neutrality can be neither negative nor unilateral. We must be prepared to play our part in this new conception of European order and to continue after the War the planned co-operation already begun under its exigencies. In consultation with those countries which now share with her the fortunes of war, Great Britain must at least lay the foundations of a new economic order which will take account of their interests as well as her own, and will enable their industries and their agriculture to flourish side by side with her own.

Something more than this, however, is involved in an effective reply to the Nazi policy and tyranny. It is not enough to develop by persuasion and negotiation a European federation or system of freer trade, stable rates of exchange and greater economic regions. The democratic order implies indeed an international association with certain machinery, for which the League of Nations provides precedents and lessons. It implies participation by all countries which believe in freedom rather than tyranny, in persuasion rather than force, so that there is sufficient good will to outweigh any possible ill will. But to work the new machinery a new spirit is wanted.

The admirable article in the *Round Table* derives its special value from its insistence on this point. The new order towards which the free peoples are groping can only be brought forth under the dynamic inspiration of a great ideal, and the formulation of this ideal is indeed an essential part of our war strategy if we are to meet the almost fanatical devotion which Hitler has inspired for their ideal in the German people. To the courage, endurance, self-sacrifice and faith of the nations which believe in justice and liberty there are indeed clouds of witnesses. Their ideals await expression in prophetic utterance.

We have not, as the *Round Table* reminds us, developed the outlook demanded by modern conditions. While science has abolished distance, unified the world, and made five continents adjacent countries, we are still inclined to retain the isolated, provincial minds of an age to which steam and electricity were unknown. The next stage in human progress is to discard the idea that self-preservation and national interest should be the only principles which determine foreign policy; and to believe that all nations, within the limits of their powers, have a duty to help actively to make justice, mercy and freedom prevail, and that the iniquity of the sufferings of other peoples are not merely their own concern but even a disgrace to the world. Only when that day dawns shall we have acquired a mind adequate to the conditions of modern civilization, and discovered an ideal more inspiring and effective than that offered by the Nazi regime.

AFRICAN SURVEY

Focus on Africa

By Richard Upjohn Light. (American Geographical Society, Special Publication, No. 25.) Pp. xv+228 +145 plates. (New York: American Geographical Society, 1941.) 5 dollars; 3 dollars to Fellows.

DR. LIGHT'S book presents us with a new technique in the methods of study travel in Africa—the use of the private aeroplane. Travel by motor-car has many obvious advantages for the student of African conditions, but is subject to two serious drawbacks. In eastern and equatorial Africa and some parts of West Africa, the traveller is confined during the rainy season to a few all-weather roads. Moreover, the great distances impose on him at all times an irritating waste of time. One is apt to forget, for example, that the area of French West Africa is greater than that of the Indian Empire; that the Belgian Congo is five times the size of France; or that the Union of South Africa, including its mandate, has four times the area of Germany. Here the aeroplane certainly has the advantage. But there is at present a very grave obstacle in the paucity of landing grounds and of metereological information, away from the main routes taken by commercial airways. Dr. Light's journey took him from the Cape, through the Rhodesias, Tanganyika, Kenya, Uganda and the Sudan, to Cairo. Air facilities are good in the Union, and fairly well developed in Southern Rhodesia; in Northern Rhodesia and East Africa they are very limited. It would have been interesting had Dr. Light's journey allowed him the opportunity of comparing conditions in the Belgian Congo, where the authorities appreciated, at an early date, the value of internal air communications, and have for a number of years maintained an efficient local service through the Sabena organization.

Dr. Light, unlike many of his predecessors in African air travel, has brought a trained scientific mind to bear on what he has seen in Africa. He is a physician who has devoted himself to the surgery of the brain and spinal cord. But he has also had a long experience of flying, in the course of which he has made a photographic reconnaissance of parts of the Rocky Mountains, and has completed a seaplane voyage round the world. This combination of man of science and competent airman must be rare. It is characteristic of the spirit in which he made this journey that, before setting out, he had (as his work indeed amply proves), made a very thorough study of the conditions of the territories he was to visit. His statements of fact are well documented, and the reader has the advantage of a well-selected bibliography of works on the current scientific and sociological problems of Africa. He had the good fortune to enlist the interest of the American Geographical Society of New York, and it was doubtless its generosity which enabled him to furnish the reader with maps on a far more liberal scale than most contemporary writers have found possible. There are no fewer than three hundred aerial photographs in this volume. They are of unusual excellence, and Dr. Light was indeed fortunate in having in the person of Mrs. Light a companion who was obviously so skilled in the use of the camera.

Dr. Light would no doubt himself agree that his book is of the character of a reconnaissance rather than of an attempt to make any original contribution to our knowledge of Africa. But it has a somewhat subtle merit of its own, and one which gives it a very real value. At the end of an attractive and pleasantly told narrative (including an interesting account of a visit to the game reserves on the Serengeti plains), the general reader will find himself in possession of a knowledge of African problems which he himself would scarcely have sought in specialist studies, and would not have found in the lighter type of travel book. Dr. Light comes nearest, perhaps, to an original contribution to our knowledge of Africa in his aerial studies of Kilimanjaro (where his photographs afford a useful supplement to those of the Swiss aeronaut, Walter Mittelholzer), the Ngorongoro crater (which still offers problems on which geologists hold conflicting views), and, above all, of the Ruwenzori massif. Cloud and rain conditions have always given this mountain an elusive character. Though the neighbouring territories had frequently been traversed before 1888 by competent observers, it was not until that year that Stanley and Stairs proved to an incredulous world the existence of its snow peaks. Its physical features have since become well known through Sella's wonderful photographs (taken during the Duke of Abruzzi's expedition), and the accounts given by Humphreys, Tilman and Shipton, and by the later Belgian and German parties. But aerial photographs are limited to those which Humphreys, after many disappointments, succeeded in taking in 1931. Dr. Light had also some disappointments, but it is fortunate that in the end a clear day permitted him to give us the excellent views which form Nos. 193–213 of his series. HAILEY.

CAMOUFLAGE IN WARFARE

The Art of Camouflage

By Lt.-Col. C. H. R. Chesney. With four Chapters by J. Huddlestone. Pp. 252+12 plates. (London: Robert Hale, Ltd., 1941.) 8*s.* 6*d.* net.

TO the evolutionary biologist, especially if he is a field naturalist with tropical experience, there are few subjects more fascinating than the camouflage devices of the animal kingdom. It is only recently that NATURE reviewed what must remain for many a day the greatest comprehensive work on this subject, H. B. Cott's "Adaptive Coloration in Animals" (NATURE, 146, 144; 1940). I had the advantage in my early days in the Gran Chaco of coming into very intimate contact with the subject both as a biologist and as one depending for his food on his success as a hunter. This experience incidentally drove home the fact, by no means generally appreciated, that there is a fundamental difference between the camouflage of small animals and of large. In the former, such as insects or small lizards, the dominating principle is that of imitative colouring to resemble the background or surroundings and in this group occur by far the most perfect examples of animal camouflage. The most common of Nature's backgrounds—the chlorophyll green of vegetation—finds an astonishingly perfect match in many animals—for example leaf insects or tree frogs or certain parakeets. Even within the limits of the group of parrots the imitative coloration is no longer found in the larger representatives, such as macaws or cockatoos. Among the larger animals in general it is absent, even where green vegetation forms the normal background.

The explanation of this curious fact is that the obliterative effect of imitative colouring becomes in a larger animal overborne by the effect of light and shade in showing up the modelling or relief of the body, precisely as an artist would depict it by the shading of his pencil or pastel drawing. To secure effective camouflage, Nature simply obliterates these differences in shade: the high lights on the back by dark pigment; the shadow underneath by white; and between these two extremes by compensative or counter-shading so as to cancel out exactly the differences in intensity of illumination. This counter-shading is the basic factor in the camouflage of many wild creatures in which the bulging relief of the body, so conspicuous in an ordinary domesticated animal, seems entirely flattened out.

Apart from its relief, the nature of a large object is commonly recognizable from its forming a continuous patch of colour or tone bounded by a characteristic outline. This is effectively counteracted in certain animals by a method totally different from counter-shading, namely, the so-called 'dazzle', in which the body bears a pattern of violently contrasting tones, such as the black and pale yellow of the zebra or jaguar. The functions of this 'dazzle' are two, namely, (1) disruptive, in that it breaks up the apparent continuity of surface and outline, and (2) distractive, in that its violent pattern grips the attention so that the fleeting glance fails to call up the mental picture of the particular animal.

It was when present at the opening of the Kiel Canal in 1895 that the sight of the obliteratively coloured warships of Germany and France in their uniform 'battleship grey' led me to realize the extent to which man in his war camouflage falls short of what is attained by Nature in the animal kingdom. The effect of the grey coloration was obviously interfered with by differences in light and shade, which detracted from the obliterative effect not merely of the ship as a whole but still more so in the case of those details which on one hand betray the character of the ship and on the other hand, through their perspective, play an important part in showing how the ship is heading. No attempt had been made to counteract those disturbing effects by the application of counter-shading; nor had any attempt been made to obscure the form of the ships or of their details by destroying the obvious continuity of their surface and outlines by the employment of 'dazzle'.

It was this experience at Kiel, superimposed on the earlier experiences in South America, that led to my taking up seriously the subject of war camouflage and suggesting—apparently for the first time—that war camouflage, so far as camouflage by means of paint is concerned, must, to secure full effectiveness, be in accord with those principles, (1) counter-shading and (2) 'dazzle', to which is due the effectiveness of camouflage in the larger animals. These suggestions were communicated to the Admiralty and War Office during the War of 1914–18 and simple instructions as to carrying them into effect were promulgated to the Fleet in November 1914 and will be found reprinted in the *Nautical Magazine* of July 1940. The soundness of these general principles must be borne in mind by anyone criticizing either the carrying out of camouflage in practice or its literary exposition.

Lieut.-Colonel Chesney has produced a readable volume on the art of camouflage. Its contents are in some respects of an unexpected nature. The introductory section by J. Huddlestone deals with various general considerations (in which it is pleasant to note the tacit admission of the part played by the coloration of animals in providing the foundations for the subject). This section of some forty pages is followed by one of seventy-two entitled "Material Camouflage", and this in turn by the concluding section of some eighty pages devoted unexpectedly to "Strategic Camouflage"—the camouflage of military intention—including chapters on Napoleon, Stonewall Jackson, the Boer War, and the War of 1914–18.

Though the whole book is thoroughly readable, it is the section entitled "Material Camouflage" which will attract the ordinary reader desirous of obtaining information about war camouflage in the ordinary sense. For camouflage in Nature he will turn to the great work by Cott: for strategic camouflage he will consult the military historian. Parts of this section are excellent, more especially those parts which deal with the author's own valuable work during the War of 1914–18. In introducing his story of camouflage during that war, the author remarks that "camouflage in practice is not so much a matter of making dream pictures as of organization and practical adaptation of materials". There is much truth in this statement, which expresses quite fairly the attitude of those responsible for camouflage work during the former war. Its fault and theirs lay in the apparent unawareness of the teachings of Nature and her demonstration of the overwhelming importance of the principles of counter-shading and dazzle. In stressing the importance of organization it seems strange that there is no mention of Mr. Norman Wilkinson, who did so much in the way of organizing the large-scale application of dazzle to ships during the later stages of the War. This is not the only strange omission in Colonel Chesney's book: I find nowhere any mention of Dr. Hugh Cott, to whom the country owes the first demonstration—within the last year—of the marvellous potentialities of counter-shading when carried out under the supervision of a scientific expert.

The really valuable kernel of the book is to be found in the latter part of Chapter v, with its most interesting account of the use of net camouflage; in Chapter vi on civil camouflage; and in Chapter vii on military camouflage in the future. These are well worth perusal: they put clearly and effectively many considerations of importance which, embodied in an attractive popular work, may perhaps gain more attention from the powers-that-be than when urged privately by the scientific specialist. Such points are the importance of developing the use of smoke screens on land, the use of black paint, the reduction in height of hangars and other buildings, the use of growing trees (but the absurdity of merely painting trees upon the walls of an edifice), and the dispersal of accommodation in a number of small buildings irregularly sited.

The author is sceptical about the efficacy of ship camouflage, but it should be borne in mind that in the War of 1914–18 this was restricted to dazzle, without the necessary scientific supervision and unaided by counter-shading, and that even with these imperfections it was regarded as of distinct use by the mercantile marine and by hard-headed underwriters.

When a new edition is called for, no doubt the author will correct obvious slips and misspellings such as Kallina, Portorus and Sir A. J. Thompson; and he should really look up the history of the word 'camouflage'. JOHN GRAHAM KERR.

INTENSIFICATION OF BRITISH AGRICULTURE

The New Farming: Continuous Cropping by the Wibberley System
By Tom Wibberley. Pp. v+171. (London: C. Arthur Pearson, Ltd., 1941.) 8*s*. 6*d*. net.

DURING the War of 1914–18, the late T. Wibberley published his book "Farming on Factory Lines", in which he advocated more continuous systems of cropping than those generally in use. It was an interesting book, well written, showing on every page the writer's forceful personality; it certainly induced a number of people to examine the proposals even if they were not persuaded to adopt them. Much of the material had been collected while he was in Limerick as agricultural instructor, and later when he was appointed professor of agriculture at University College, Cork, the chair having been specially founded by the late Howard Harrington, who was attracted by the possibilities offered by the system.

Now in this War his son, also T. Wibberley, has revised and reissued the book in the hope that it may prove of value both in the present conditions and in the new ones that will arise when the War is ended. Under the old four-course rotation the arable land is cropped for about 38–40 months out of the 48, and is left bare or in stubble for the remaining eight to ten: broadly speaking for the space of two winters. During each of these it is very desirable that the land should be ploughed and exposed to the frost so that the soil may build itself into the crumb structure so necessary for securing a good seed bed. If the winters are dry and frosty all goes well, but often they are wet and mild and the soil becomes sticky and loses valuable nitrates by leaching. The essence of the "factory lines" methods is to grow crops during these months, so avoiding the loss of nitrate and adding to the total quantity of produce on the farm. The insertion of catch crops is an old device, and has been much practised by the arable sheep farmers on the South Downs and by other groups of farmers, but there were sufficient distinctive features about the Wibberley methods to justify some claim for novelty.

The methods were tested in Ireland and were said to give satisfactory results. In England, on the other hand, catch cropping and continuous cropping have never come into general use on any extensive scale. Autumn-sown crops make but little growth during winter in the drier arable regions of the east, and on the other hand sufficient time must be allowed for cultivation to kill weeds. Attempts at full time cropping have not usually succeeded in these regions, nor did they on Sir E. D. Simon's farm at Leadon Court, Herefordshire, although one readily agrees that if it could be done the results might be valuable. The author's statement on p. 52 that his father in one year turned out beef and mutton to the value of £5,188 14s. 7d., with a total expenditure of £81 2s. 2d. on purchased cakes and meals must make many farmers' mouths water, especially when one is told that this was largely done with tares and winter green crops. The farmers' reaction would almost certainly be: if this young man was brought up to such a lucrative system of farming, why did he ever leave it?

The old four-course rotation has been much altered in its details, and wherever possible it is certain that farmers will grow catch crops, and increase their output of fodder in every way possible. What, however, is needed in regard to the present proposals is not more writing or propaganda about them, but to put them into practice on some actual farm so that other farmers can see what they are like in operation. If the author could bring this about he would soon be able to show whether the returns justify the labour and money involved. E. J. RUSSELL.

The Moral Paradox of Peace and War

Conway Memorial Lecture delivered at Conway Hall, Red Lion Square, W.C.1, on March 23, 1941. By Prof. J. C. Flugel. Pp. xi + 52. (London: Watts and Co., Ltd., 1941.) Paper, 1*s*. net; cloth, 2*s*. net.

IN his highly suggestive and constructive Conway Memorial Lecture, "The Moral Paradox of Peace and War", Prof. J. C. Flugel gives us an acute analysis which is as pertinent to our plans for reconstruction as to the building of a world order from which war has been eliminated. Starting with an analysis of the moral qualities which are responsible for the real challenge of war and which have already led to a certain recognition of the need for a moral equivalent of war, he indicates concisely the points at which this challenge must be met in a progressive society in which full expression is given to legitimate desires and aspirations. Notably he stresses the spirit of adventure, with all it connotes of excitement, uncertainty, danger and tenseness or strenuous endeavour. Of this, as well as the social solidarity, the heightened sense of the individual being needed, and the identification with a nobler cause for which he or she is prepared to make any sacrifice, any stable order must take account of, and must seek to satisfy by discovering, a common purpose comparable in intensity with that induced by war. The great task that confronts democracy is to find a formula for integration in harmony with its own essential spirit, which will express our fundamental agreement as to the ultimate goal while preserving our present liberty of thought and discussion as to the best means of attaining this goal. As Prof. Flugel sees it—and in this most scientific workers will concur—we must learn to face the stark realities of man's place in Nature, and find in the challenge and opportunity they afford for the exercise of human genius, combativeness, courage and co-operation, the true moral equivalent of war. R. B.

Aids to Inorganic Chemistry

By R. G. Austin. Pp. x+348. (London: Baillière, Tindall and Cox, 1940.) 5*s*.

THIS small volume is not intended as a complete text-book of inorganic chemistry, but is designed to give students, who have already attended lectures on the subject, a condensed survey of the principal facts. The subject-matter covers the course required by students of pharmacy, medicine, dental and veterinary surgery.

The preliminary chapters are rightly devoted to general topics such as the atomic theory, acids, bases, salts and the periodic classification. Unlike the non-metals, the metals are considered in the same sequence as they occur in the periodic table, and this has enabled the author to stress their family relationships. The medical aspects of chemistry have been emphasized wherever possible, and the reader will find the notes on the physiological action of common inorganic substances both interesting and profitable.

The author states in the preface that "simple interpretations of the mechanism of chemical reactions have been given prominence in order that students may gain some insight into the principles of chemical change"; it is therefore surprising to find that the ionic aspect of inorganic reactions has been almost totally neglected. In spite of this omission, students of medicine and allied subjects, in search of a book containing a wealth of concise factual matter, should find the book a useful aid to their studies.

A. C. C.

This Living World

A College Course in Science. By Prof. C. C. Clark and R. H. Hall. Pp. x+519. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 22*s*. 6*d*.

THIS well-written and well-illustrated book can be recommended especially to those teachers in training who expect to teach general biology in primary or secondary schools. It displays an unusually expanded breadth of vision, thus covering all aspects of life and living. Though the book will not satisfy the needs of the student of biology, from the point of view of examinations, it would well form a supplement to his more academic reading.

In a form which combines accuracy with pleasant reading, the book presents the gist of modern knowledge about the living world, with special reference to the physical development of man and the structure and functioning of his body. Thus it is of cultural as well as simply academic value.

Radioactivité et transmutation des atomes

Par Dr Théodore Kahan. (Collection Armand Colin: Section de physique, No. 222.) Pp. 224. (Paris: Armand Colin, 1940.) 15 francs.

DR. KAHAN'S stimulating account of the more recent developments in radioactivity and the artificial transmutation of the elements will be welcomed by all students who require a short up-to-date survey of the subject. It gives a very satisfactory account of the state of our knowledge of α-, β- and γ-ray spectra which is easily followed, and also gives a discussion of the energetics of nuclear changes which is particularly clear and helpful. His treatment of nuclear reactions such as (α, p), (α, n), etc. covers all the more important aspects in a remarkably concise way. The reviewer hopes that this little volume may still be obtainable in Great Britain.

L. F. B.

The Study of the Soil in the Field

By G. R. Clarke. Third edition. Pp. 228. (London: Oxford University Press, 1941.) 6*s*. 6*d*. net.

THE third edition of this valuable little handbook of soil survey differs from the second edition only in having an appendix in the form of the instructions to surveyors, accepted by the Soil Survey Conference of Great Britain. This should add considerably to its practical utility. The author states that the time is inappropriate for a revision of the text; nevertheless it is to be regretted that, since the book is apparently (and deservedly) becoming a standard work on soil survey, the opportunity was not taken to remedy some inconsistencies in literary composition and the misuse of abbreviations which have been freely invented by the author and employed often without explanation, leaving their meaning to be guessed by the reader.

EVOLUTION OF FUNCTION IN THE MAMMALIAN ORGANISM*

BY SIR JOSEPH BARCROFT, C.B.E., F.R.S.

THE life of the mammal is a synthesis of many diverse functions. They range from the digestion of porridge to the performance of Brahms, from snoring to the niceties of mathematical analysis. Here I am concerned neither with the higher faculties of the mind nor with the lower vegetative functions of the body; but merely with that intermediate region of activity which concerns itself with the muscular movements—getting about and the like—these we share with our mammalian relations generally.

A child, for example, learns to walk. It is, so far as locomotion on its legs is concerned, capable of one kind of movement—crude, uncertain toddling. From that movement, however, quite a number of things develop, the initial ability to toddle turns unconsciously into the power either to walk or to run, and these more refined movements, when exploited by conscious intelligence, create the possibility of anything from tap dancing to tight-rope walking.

But instead of interesting ourselves in the variety and complexity of the movements into which toddling may develop, we may look the other way. We may ask: Can it not be that toddling, itself a highly complicated affair, is not a development or differentiation of some much cruder form of movement, and, if so, what is that movement and is it the parent of movements other than toddling, just as toddling is the parent of tap dancing and mastery of the tight rope? By way of parenthesis the words "just as" require a caveat. We ordinarily regard the development of walking from toddling as a question of practice. Can the same be said of intra-uterine movements?

These are the questions which I wish to attack:

(1) What is the most primitive form of movement of which the mammal is capable?

(2) Does this movement differentiate and develop into other and more complicated ones?

(3) If so, are they recognizable as the forerunners of the sorts of movement with which we are ordinarily familiar in life?

Studies of the earliest movements of which the mammal is capable have been made by a number of observers, mostly on small animals with short periods of gestation, and from several points of view.

The sheep, for example, has the advantage over small animals in that development in it is a comparatively leisurely affair and its steps are therefore easily recognizable. To quote Barron, "All the events which take place over two months in the sheep are telescoped into a single week by the rat."

The period of gestation in the sheep is twenty-one weeks—147 days; until the thirty-third day of embryonic life, the organism is not capable of any inherent movement apart from the beating of the heart. At this age it is about the length of the thumb nail and it has taken on the general mammalian form. Its eyes are well developed, its trunk, tail, fore-legs and hind-legs are all there, though in a rudimentary way. The fœtus at this age does not move except in response to a, for it, rather considerable stimulus. This stimulus is quite specific, it must be given in just the right place and the response is perfectly definite. Tap it firmly just under the eye and it will give a twist to its neck. This twist causes the head in the first place to go back, and in the second place to rotate, drawing its nose towards the point of the glass rod, or what not, with which it was tapped. Tapping no other place will elicit a movement.

Why, you may ask, is this particular point on the cheek so different from the rest of the body that a response can be elicited from it and from it alone? There is a very good reason. Here, just beneath the skin, is the end of a nerve. It is the fifth cranial nerve or, rather, a branch of it. It grows down from the brain and will ultimately supply the upper jaw and the nose with sensory fibres. This is the nerve which will impress itself on one's consciousness if one gets a spasm of toothache in the upper jaw or if one smells ammonia. It is perhaps worth noting that regionally it is the nerve which supplies the most anterior part of the body.

In case a sheep were to walk forward (the natural direction of progression) the first bit of it to run into an obstacle would be the tip of its nose, and the nerve which supplies the tip of the nose is the first sensory nerve to give a response. But by the thirty-third day the fibres of the nerve have not yet reached their destination, they have only reached the point under discussion. The reason why the face must be tapped rather sharply is because the immature endings of the nerve are definitely underneath the skin and not in it. The stimulus must be transmitted through the skin to the deeper structure.

---

* Substance of a lecture delivered at the Royal Institution on May 20. The lecture was in effect a description of a film illustrating the work of the lecturer in collaboration with Dr. D. H. Barron. Its format was dictated by that fact, especially as regards absence of documentation. Its documentation and its setting in relation to the work of other observers will be found in Dr. Barron's article "The Functional Development of some Mammalian Neuromuscular Mechanisms" (*Biol. Rev.*, 16, 1: 1941).

The nature of the movement is reflex, that is, it is caused by a peripheral stimulus, which is transmitted to the central nervous system, in this case, the brain, which passes thence to the motor nerve that supplies the neck muscle concerned. That the first movement should be a reflex, or even a movement which involves the nervous system, is not true of all forms of life. Seemingly there is a tendency in the higher forms for neurogenetic movement to appear earlier relatively to myogenic, until, as in the sheep, movements involving the nervous system occur as soon as, or even before, those of a purely muscular character.

So much for the very first movement. In the few days which follow, the principal alteration which occurs is an expansion of that. This expansion takes place in at least four different directions.

(1) The area of skin on the face, the stimulation of which will elicit the movement, becomes greater. Other branches of the fifth cranial nerve, the great sensory nerve of the face, develop, and as they do so the areas of skin which the nerve has reached become sensitive when stimulated and evoke the movement.

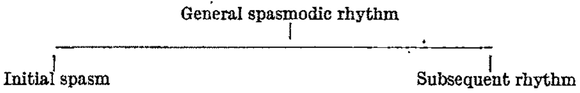
(2) The movement itself embraces an ever-increasing number of muscles, so that instead of being confined to the neck, it spreads within the next week or so to the mouth, the trunk muscles, the limbs and the tail, so that the movement amounts, not to a twitch of the neck, but to a trifling convulsion of most of the body.

(3) More than this, the response extends not merely in the number of muscles which are involved, but it also extends in respect of time. Stimulation causes not merely one spasm but a series of perhaps twenty spasms, one after the other, amounting to a rhythm.

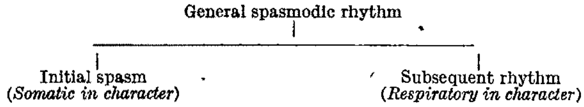
(4) A much less vigorous stimulus will suffice, as it were, to touch off the trigger of this mechanism—a drop of saline on the eye, the direction of a current of fluid into the nose or even a sharp tap on the outside of the sac within which the fœtus floats in its bath of amniotic fluid.

Up to the forty-second day (approximately) the fœtus has exhibited only one kind of movement, the spasm. This may have been more or less widespread, it may have been repeated more or less often, but fundamentally there was but one essential pattern.

Now, however, something quite new is seen. If the fœtus be stimulated, say by a tap on the nose, a rhythm of spasms follows, but the first or first two members of the rhythm differ from the subsequent ones. In the first spasm, the head is thrown back, in the subsequent ones it nods forwards. This is the commencement of differentiation of movement—for slight as is the difference between the initial and the subsequent spasms, that difference develops into something abundantly evident and of great importance. We have then :



To appreciate what has taken place, we have only to pass on a few days. The trifling difference between the initial and subsequent members of the rhythm is seen to denote a definite splitting of function. The initial spasm is shaping towards an indefinite body movement in which the limbs are largely represented whilst the subsequent rhythm affects principally those muscles which are ultimately concerned with respiration. The initial movement gives one the impression that the fœtus is trying to do something; though it is not at all clear what this 'something' may be, the subsequent rhythm gives the impression of the fœtus having been mildly out of breath as the result.



By the forty-eighth or forty-ninth day there is an obvious development of both the somatic and respiratory movements, though in rather different ways. The somatic movement becomes more purposeful in character, the respiratory movement becomes more regulated. Take these movements one by one.

One new element which enters into the somatic movement is gravitational response. When the fœtus is lying on its side, stimulation of the nose causes a twisting of the neck and body, the effect of which is to turn the crown of the head upwards towards the sky. This reaction to gravity is different in some respects from that with which we are familiar in the mature organism. In the latter the semi-circular canals play an active part, but all observers agree that this is not so in the fœtus, or rather in the fœtus at forty-eight days; the response is of a different nature. It is due to the unequal pressure on the two sides of the trunk and perhaps elsewhere. The side on which the fœtus is lying naturally bears its weight, and it seems to be the fact that the pressure on this side is the stimulus to the gravitational response. This may not be the whole stimulus, but whether it is or not, if a piece of cardboard be placed firmly on the upper side of the body so that both sides are pressed upon, the gravitational response disappears.

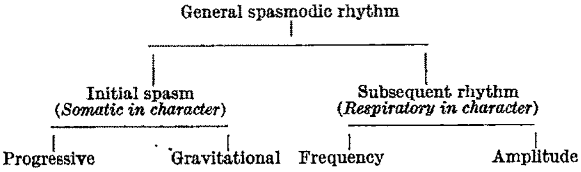
As regards the limb movements : those of the fore-limbs are not symmetrical either. Both are stretched forwards as far as the knee, but whereas the uppermost fore-leg is stretched right out, all the joints being extended, with the lower fore-limb it is different ; it is flexed at the knee and the toe is pointed backwards.

The whole movement in a crude way seems to be an effort on the part of the fœtus to rise from the ground, in just the way which it does shortly after birth. The hind-legs are gathered up underneath the belly of the fœtus. If, then, we may stretch the word progression to include rising from the ground, we may regard the movements seen on the forty-eighth day as containing the germ of progressive movement.

As regards the respiratory type of movement* on the forty-eighth–forty-ninth day, two alterations are taking place.

(1) The first is that the respiratory rhythm becomes daily more easy to evoke. By the forty-ninth day almost any muscular movement of the fœtus, however trifling, will touch off a respiratory rhythm ; indeed, if at this time the observer lays the fœtus in his hand it is scarcely possible to hold it sufficiently still to prevent stray alterations of tension in the muscles from evoking some response.

(2) The second advance in the evolution of function is the gradation of the respiratory rhythm to correspond with the force of the muscular movement which preceded it. Thus, if the fœtus be held very still, the respiratory responses due to adventitious movements will be relatively slow and shallow, but if the fœtus be given a sharp tap so that it makes a dramatic effort, that effort is followed by a rhythm which is not only more rapid but is also more powerful. We therefore have reached the following position.

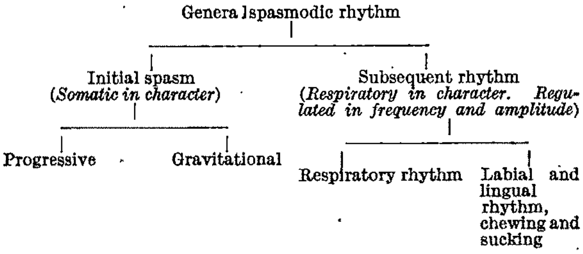


Somewhere about the seventieth day, the movements of the mouth are very prominent. If an object be placed inside the buccal cavity, powerful rhythmic movements are often seen. These resemble both chewing and sucking ; it is not quite accurate at this stage to describe them as either, nor is their relation to other movements clear. In this matter, as in many others, we have been helped by the following fact : on exposure or mild asphyxiation of the fœtus, its movements change ; those functions of the brain which have been developed most recently are first affected, and therefore as the fœtus during the progress of this experiment deteriorates in vitality, its movements tend to resemble those which it made at an earlier stage of fœtal life. A seventy-day fœtus as it deteriorates will tend in its type of movement shortly to behave like a sixty-day fœtus, then like a fifty-day one, and so on.

In such deteriorating embryos, it may be seen that the rhythmic mouth movements which at seventy days appear to be quite distinct from any others, gradually merge into the general respiratory, from which they have no doubt been differentiated.

I have spoken a great deal about the fifth cranial nerve, and I would end this part of my lecture by collecting some of the points which I have stated about it. The earliest reaction which it gave me was local ; as the fœtus grew, the reaction became widespread, but by the seventieth day it has become strictly localized again. I emphasize this sequence because, though exhibited in its most striking form by the fifth cranial nerve, it is true of all sensory nerves, the reaction to stimulation of them being, initially, local, becoming more widespread but finally settling to a local response.

The following chart sums up, so far as we can go here, the information at our disposal about the differentiation of actions of various sorts :



CHARACTER OF MOVEMENT

Hitherto I have spoken of the evolution of a number of actions, if I may describe them by that term, breathing, chewing, getting up and the like. But any of these actions may change in character ; it may be rapid, jerky and spasmodic, or it may be drawn out and gradual, or, again, it may even be a sustained movement in which there is an actual static phase, such as the Nazi salute. The evolution of the actions which I have described has all concerned itself with those parts of the central nervous system into which sensory nerves enter and from which motor nerves leave—the hindermost part of the brain (the medulla) and the spinal cord. In general, the organization of action takes place from above downwards, and it is initiated at the point of entry of the nerve which receives sensations from the face and nose and is modified later by influences entering the spinal cord from the arms, the trunk and the legs. But if in the central nervous system this evolution of function takes place from the point of entry of the facial nerve backwards, it takes place in a different sense from that same point progressively forwards. The forward development is concerned less with what the fœtus does, than with how he does it.

---

* It must not be supposed that these movements cause anything to go into or out of the chest at this age. The windpipe is not open, and owing to the softness of the chest wall no measurable negative intra-thoracic pressure is induced by the rhythmic movements of the diaphragm, the intercostal muscles and the throat muscles.

The first movement of all was a simple twitch or a minute spasm; when later it became necessary to expand this twitch into something which stretched over a longer time, the expansion consisted of the extension of a single twitch into a series of twitches—a rhythm, but the character of each individual jerk of which the rhythm consisted was unaltered; even when differentiation commenced the twitches were still twitches.

Between the forty-fifth and fiftieth days, however, the movements gradually assume a different character, namely, they take on an air of deliberation; if the arm is thrust out, the movement is less that of the boxer getting in his punch than that of the constable raising his hand to stop the traffic.

Just as the jerky movements obtained from the lower parts of the central nervous system gradually took on a certain appearance of purposefulness and became evidently the forerunners of the types of movement which we actually recognize, so these sustained movements also tend to fall into certain patterns which we recognize as postural. In association with the turning of the neck to which I have already alluded, there are harnessed the corresponding movements of the legs, that is, the fore-leg on the side to which the nose is turned is extended, whilst the other fore-leg tends to be flexed or partially so. At a later date, characteristic postural movements of the hind-legs, the trunk and the eyes are associated with this twisting of the neck. Indeed, it is only necessary to take the head between one's fingers and rotate the neck alternately in one direction and then in the other to produce this corresponding marionette-like movement of the eyes and limbs.

These postural movements are essentially those described by Magnus and de Klejn; the difference between their demonstration of the movements on the adult animal and our own on the fœtus is that they, in order to secure the movements, had to perform a surgical operation in which the mid-brain was relieved of the influence which dominated it, notably the semi-circular canals. In the case of the fifty-five day sheep's fœtus, no such surgical operation is necessary because what Magnus and de Klejn cut away has not at this age functionally developed. The alteration from the simple jerky type of movement to the more deliberate postural type is attributable to this development of the mid-brain and its influence on the centres below it.

The initial phase of postural movement soon disappears; by the sixtieth day, if the fœtus be delivered, it exhibits a different picture, the fore-legs are tensely stretched out side by side, the head and the tail are extended, and the fœtus presents the appearance of an animal suffering from what is known as 'decerebrate rigidity'—a condition which, again, can only be obtained in the adult by a surgical operation, that of severing the foremost parts of the brain from parts behind them, and so ridding these latter from the influence of the higher centres. But once more, in the case of the sixty-day fœtus, no surgical operation is necessary for the simple reason that the higher centres in question have not developed physiologically—function has developed upwards far enough, but only far enough to produce this rigidity.

The picture of rigidity does not last many days. From about the fiftieth day onwards a characteristic has been gradually creeping into the picture, slight at first, but quite evident; by the seventieth day it becomes dominant, namely 'inhibition'. During the eighth and ninth weeks, this growing inhibition amounts to no more than a certain evident restriction of movement associated with the postural patterns which I have described. On the seventieth day, however, if the fœtus be delivered, so far from exhibiting spasmodical or postural movements, it gives the impression of being dead or at all events soundly asleep. If mechanically stimulated, the stimulus must be strong if it is to be effective, and even at that the response is only very restricted. This suppression of movement means that function has progressed well up into the fore brain. That motility has not been abolished but only suppressed is easily proved. It is only necessary to leave the fœtus exposed for a while or to pinch the umbilical cord in order to uncover the functions which I have tried to describe. A more elegant proof is furnished by intra-uterine transection of the central nervous system. It is possible to cut across the brain or cord at any given point, between the fiftieth and seventieth days, without impairing the growth of the fœtus. If, at seventy days, the section consists in mere severance of the cerebral hemispheres from the rest of the central nervous system, no change in the behaviour of the fœtus can be seen, but if the section is lower down—about the middle of the fore brain—the lower parts are freed from 'inhibition' and the fœtus exhibits the 'rigidity' pattern of sixty days. If the section is just below the 'pons Varolii', the fœtus exhibits almost unceasing jerky movements, which are both somatic and respiratory and are strongly reminiscent of a fœtus of about forty–fifty days. At seventy days, however, the fœtus appears to be in a sound sleep and in this sleep we may leave it.

MYOSIN BIREFRINGENCE AND ADENYLPYROPHOSPHATE

By DR. JOSEPH NEEDHAM, F.R.S., DR. SHIH-CHANG SHEN,
DR. DOROTHY M. NEEDHAM AND DR. A. S. C. LAWRENCE,
BIOCHEMICAL LABORATORY, UNIVERSITY OF CAMBRIDGE

OUR knowledge of the nature of muscular motion has hitherto been divided into two main fields of successful analysis. First there was the discovery of the phosphorylation cycles whereby energy is transferred from carbohydrate breakdown to the muscle fibre; here the earliest landmarks were the investigations of Fletcher and Hopkins[1] and of Harden and Young[2] (see the papers of Parnas[3] and D. M. Needham[4] for up-to-date reviews). Secondly, there was the discovery of the elongated or anisometric character of the particles of muscle-globulin (myosin), demonstrated in the classical paper of v. Muralt and Edsall[5], leading to the application of X-ray techniques to the problem, and the establishment by Astbury[6,7], that muscular contractility is essentially a molecular contractility of protein chains. The exact connexion between these two orders of fact, however, still remains obscure.

In order to bridge this gap, the most promising point of departure seemed to be the important finding of Engelhardt and Ljubimova[8] in 1939 that the enzyme adenylpyrophosphatase is either myosin itself or some protein very closely associated with it. This was confirmed by one of us (D. M. N.) in the following year (unpublished) and recently by Szent-Györgyi and Banga[9]. Its importance lies in the facts: (1) that the breakdown of adenylpyrophosphate is, among the processes of intermediary metabolism in the muscle, that nearest in time to the contraction of the fibrils, and (2) that although some adenylpyrophosphate is broken down by transfer of phosphate to hexosemonophosphate (by an enzyme not present in the myosin fraction), the quantitatively largest part of its breakdown probably occurs by splitting off of free phosphate under the influence of the enzyme adenylpyrophosphatase. It was thought of interest, therefore, to study the effect of adenylpyrophosphate upon the flow birefringence of myosin. The myosin sols were contained in a small annular cell holding just less than 1 c.c., mounted on the fixed stage of a Swift-Dick polarizing microscope, and having the outer co-axial cylinder driven at speeds variable up to 500 rev./min. (shear-rate 4·08 cm./cm./radian). Myosin preparations were also examined at higher dilutions in the co-axial viscosimeter referred to in a recent communication in NATURE by Lawrence, Needham and Shen[10] (shear-rates of 0·73 and 4·2 cm./cm./radian according to the diameter of the inner cylinder used).

Myosin preparations showing strong flow birefringence (Δ 50–80°; Ψ 50–60° for 1–2 per cent sols at 20° C.) were obtained from rabbit muscle by the usual method. Until this year, myosin sols prepared in Cambridge had nearly always been non-birefringent, and although the reason for this is being made the subject of a special study by Dr. K. Bailey, it may be said here that, provided the rabbit has been starved for twenty-four hours before death, the myosin never fails to show flow birefringence*. In the light of observations such as those reported below on the viscosimetry of myosin, it is likely that these differences are simply due to the size and shape which myosin particles assume when extracted from muscle cells under different conditions. Some preparations of myosin, however, which do not show flow birefringence, may show anomalous flow at low shear-rates, and are then analogous to the preparations of globulin from amphibian embryos described by Lawrence, Needham and Shen[10].

If now a myosin sol containing about 3 per cent of the protein is mixed with adenylpyrophosphate at pH 7·0, a considerable decrease in the flow birefringence intensity is immediately observed, for example, 65°–45° (see Fig. 1). This fall occurs in less than a minute at room temperature, but at 0° C. is so lengthened as to allow of its being plotted on a curve. With adenylic acid or inorganic pyrophosphate, the fall is either absent or slight. An important feature of the effect is that it is reversible; after it has occurred, the flow birefringence intensity of the sol rises, reaching its original level in about 2 hr. at 37° C. or overnight at room temperature, and then rising beyond it. It may be added that strict control of the salt concentration is essential, since if increasing amounts of solid potassium chloride are added to a white, almost salt-free, gel of myosin, the flow birefringence intensity continually decreases to reach a minimum at molar concentration, when the sol so formed is most transparent. After that point, with increasing amounts of the salt, the flow birefringence intensity increases, apparently because of the increasing amounts of transparent gel formed by salting-out. Hence in the above-mentioned experiments the ionic strength of the adenylpyrophosphate or other substances added was compensated for in such a way as to bring all samples to a final concentration equivalent to the ionic strength of 0·75 *M*KCl. In order to avoid the effects described by Edsall and Mehl[11], potassium was the only cation present. Finally, viscosimetric measurements indicate that the relative viscosity decreases, but not the anomaly of flow (see Fig. 2*a*).

---

* The suggestion that the state of nutrition might be a factor was due to Dr. H. Lehmann.

Interpreting the effect, we consider that the first change is a moderate shortening of the myosin particles, with or without a certain amount of disaggregation. This seems not quite analogous with the changes produced by increasing potassium chloride concentrations below molar, for here, although the flow birefringence intensity also falls, and correspondingly the relative viscosity, the anomaly of flow decreases and eventually disappears. Hence the particles must become drastically shorter as well as possibly smaller. After the molar point is passed, though flow birefringence and relative viscosity increase, the viscous anomaly does not again become observable, probably because although the particles lengthen, their axial ratio decreases owing to some form of aggregation. In all such explanations we provisionally ignore the role of intermicellar forces (*cf.* Langmuir[12]) which may well be of importance in the relatively dilute solutions we have used, and must almost certainly be so in more concentrated mixtures such as occur in the muscle fibril itself.

The subsequent rise in flow birefringence intensity during the action of the enzyme, however, is more difficult to interpret, since that of myosin sols in potassium chloride alone will, if placed at 37° C., steadily increase until they set to a thixotropic gel. We have frequently observed in this respect what may be a protective action of adenylpyrophosphate, the sol returning to approximately its original birefringence intensity, and then remaining there for some hours, only in the end to rise. In such circumstances, the parallel increases in relative viscosity and viscous anomaly are also inhibited. This effect on the particle shape recalls the protective effect of adenylpyrophosphate on the enzymic activity itself at 37° C. discovered by Engelhardt and Ljubimova[8], and confirmed by us.

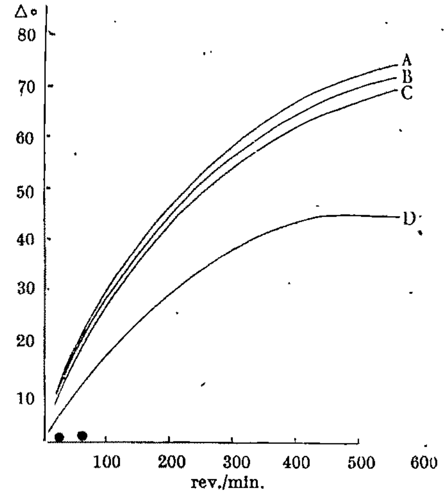


Fig. 1.

REDUCTION OF FLOW BIREFRINGENCE OF MYOSIN BY ADENYLPYROPHOSPHATE.

A, POTASSIUM ADENYLATE; *B*, CONTROL; *C*, POTASSIUM PYROPHOSPHATE; *D*, POTASSIUM ADENYLPYROPHOSPHATE.

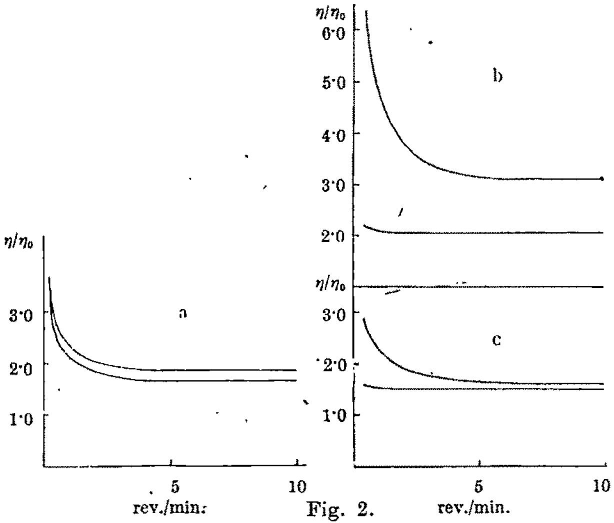

Fig. 2.

VISCOSITY OF MYOSIN.

(*a*) EFFECT OF POTASSIUM ADENYLPYROPHOSPHATE; (*b*) INCREASE OF ANOMALOUS VISCOSITY IN A DILUTE BIREFRINGENT MYOSIN KCl SOL HELD AT 37° C. FOR 2 HR.; (*c*) RESTORATION OF ANOMALOUS VISCOSITY TO A NON-BIREFRINGENT MYOSIN KCl SOL BY TREATMENT AT 37° C. FOR 2 HR.

The reversibility of the change in flow birefringence intensity of myosin is of much interest, since according to Edsall and Mehl[11], no treatment has ever hitherto been found to restore flow birefringence when this property has once been lost. We find, however, that adenylpyrophosphate is not unique in causing a reversible fall in flow birefringence intensity. After the flow birefringence has been reduced or abolished by ions such as Li', Ca'', Mg'', or NH_4', or by urea, all that is required to restore it is a short period at physiological temperature (or under some conditions even at room temperature), and its original value is reached long before any signs of gelation appear. It is even possible in this way to restore flow birefringence to a myosin sol which on long standing at 0° C. has lost the property. During such a restoration, or during the rise of birefringence from its original value in, for example, a 0·5 *M* KCl myosin sol subjected to 37° C., relative viscosity increases and flow anomaly appears, first slightly, then markedly (see Fig. 2 *b*, *c*). The particles must therefore become very much longer.*

*The restored flow birefringence intensity cannot be ascribed to the photo-elastic effect in a gel under strain because (a) anomalous viscosity appears before the relative viscosity has much increased, and (b) the angle of isocline remains about 70° showing that the particles are orienting freely.

Thus the physiological significance of the adenylpyrophosphate effect, which might at first sight seem to be lessened by experiments on simple salts, regains its force in that these themselves give reversible changes in flow birefringence and viscosity, which should throw light on the reversible changes in the intact muscle cell. One cannot, of course, compare too closely the behaviour of myosin in the muscle cell and myosin isolated in the form of a sol. In the muscle the contracting particles do work against resistance; in the sol this does not happen. It should be made clear, however, that potassium adenylpyrophosphate is more effective in causing immediate fall of flow birefringence than any of the other salts so far studied, 1–2 *M* concentrations not being nearly as effective as 0·1 *M* adenylpyrophosphate. None of the effects here described can be due to differences in the refractive index of the dispersion media used, since these are very small (within the limits 1·3336–1·3437). What connexion the reversible changes in flow birefringence here described have with those occurring in the birefringence of the intact muscle fibre remains to be determined. It is known from older work, put on a firm basis by v. Muralt[13] in 1932, that during a single isometric twitch the birefringence decreases by some 35 per cent, returning to its original value by the end of relaxation. It has also been found by Buchtal and Knappeis[14] that in the absence of contraction, changes in hydrogen ion concentration and salt concentration in the medium surrounding a contractile isolated muscle fibre bring about slower reversible changes in its birefringence. We doubt if there is much to be gained by referring to the myosin sol after its birefringence has fallen and it has begun to dephosphorylate adenylpyrophosphate as 'denatured', unless we are careful to say that the 'denaturation' (which involves neither changes of solubility, nor, as has been shown by Greenstein and Edsall[15] in the case of the salt effects, changes in titratable –SH linkages) has not gone beyond an early reversible stage at which it is compatible with active enzymic breakdown of the adenylpyrophosphate.

How exactly the adenylpyrophosphate interacts with the myosin in normal muscle remains unclear. But there is a suggestion in the facts already known (entertained for some time past by one of us (D. M. N.) and now put forward in a rather different form by Kalckar)[16] that myosin might be phosphorylated and dephosphorylated, occupying thus the last link in the chain of simultaneous transfers of phosphate ions and energy. As is well known, adenosinediphosphate can be phosphorylated according to circumstances by creatinephosphate, phosphopyruvic acid, or diphosphoglyceric acid. We suggest that while it acts as a phosphate acceptor towards these substances, adenosinetriphosphate (adenylpyrophosphate) acts as a phosphate donator towards the contractile protein itself. Contracted myosin would thus have adenylpyrophosphatase activity and phosphate would be transferred from the adenylpyrophosphate to some part of the protein molecule, which would simultaneously extend. Extended myosin would then be in phosphorylated form and charged with energy. When the physical changes touched off by the nerve stimulus occur, inorganic phosphate would be set free, and the energy available from this dephosphorylation used in contraction. It might even be, in view of the effects described in this note, that the contraction of the particles in the fibril would be occasioned by a sudden contact (brought about by changed permeability) with the resynthesized adenylpyrophosphate, the substrate, itself. Such possibilities obviously invite further study.

These experiments, which indicate that adenylpyrophosphate has a direct influence on the relative optical anisometry and on the shape of myosin particles, and possibly on their intermicellar forces, will be continued and extended as better optical and other apparatus becomes available.* They form part of a general investigation of the shape of protein particles arising out of an interest in the proteins of developing embryonic cells. Although they primarily concern the connexion between energy-transfer and myosin-fibril contraction, they are perhaps not without a relevance to inductor-reactor systems in embryos undergoing morphogenesis. The possibility should now be borne in mind that an inductor might be, not a co-enzyme or an auto-catalytically active protein, but a substrate, and that the changes in protein configuration which will lead to a specific histogenesis might be the result of the unavoidable action of an enzyme protein in the competent cell upon the inductor itself.

---

* The authors wish to take this opportunity of thanking Prof. J. D. Bernal and Dr. J. F. Danielli for the stimulus and benefits of their conversation, and Prof. Tilley for the loan of valuable apparatus.

OBITUARIES

Prof. A. Lapworth, F.R.S.

As a professor of chemistry, Arthur Lapworth will be remembered for his distinguished pioneer work on the mechanism of organic reactions and the reactivity of organic compounds, which was recognized in the award of the Davy Medal of the Royal Society. His colleagues in the University of Manchester and his many other friends will also remember, with gratitude and affection, such characteristics as his devotion to the maintenance of high intellectual standards in the University, his encouragement of co-operation between workers in different branches of science, his lively and expert interest in half a dozen fields outside his scientific work, and his sensitive sincerity and modesty.

After graduating at Mason College, later the University of Birmingham, where his father had become the first professor of geology, Lapworth began his research career in H. E. Armstrong's department at the City and Guilds Institute, South Kensington. The careful study of the sulphonation of the ethers of β-naphthol, for which he obtained his London D.Sc. in 1895 at the age of twenty-three, laid a foundation for his interest in aromatic substitution and isomeric change. With F. S. Kipping as senior collaborator he entered the terpene field with studies of bromocamphors and camphorsulphonic acids. Later, as lecturer in chemistry at the School of Pharmacy, Bloomsbury, he extended this work independently to the extent of some twenty papers, making particularly important contributions to the clearing up of the tangle of the monocarboxylic acids derived from camphoric acid. His report on the constitution of camphor, published by the British Association in 1900, is regarded as a classic.

Parallel with this work and later, when Lapworth had become head of the Chemistry Department at the Goldsmiths' Institute, he developed his characteristic contribution to the study of organic reactions. His attack on this problem shows two interacting aspects. On one hand he carried out fundamental investigations of the kinetics of a variety of organic reactions, which provided him with chosen foundations for theoretical discussion and many workers with a basis for extensive studies of further detail. On the other hand, he was always seeking generalizations concerning reactants and reactions which would be more comprehensive than the very limited analogies which were the stock in trade of organic chemists. He saw that very ambitious speculations would get lost in the bewildering mass of data concerning the behaviour of carbon compounds, but that progress could best be made in stages by accounting for well-chosen groups of related phenomena. Generalizations such as he put forward are necessarily open to a variety of criticisms, and it was only when, in the fullness of time, they were seen to build into wider theoretical conceptions, that the extraordinary soundness of Lapworth's insight gained full recognition. He combined what sometimes seemed almost artistic convictions about the significance of particular analogies and conceptions, with precision of thought in stating and applying them. Unfortunately, some of his critics skimmed over the outlines of his ideas, and on applying their impressions met with inevitable disappointments.

Lapworth's recognition in 1898 of the generality of isomeric changes of the form

$$M-R_\alpha-R_\beta=R_\gamma \rightleftharpoons R_\alpha=R_\beta-R_\gamma-M$$

led to his discovery that the γ-position in crotonic ester shows reactivity similar of that characteristic of the α-position in saturated esters. He first established essential features of cyanohydrin formation by a typically simple colorimetric method using yellow camphor-quinone, and from this beginning he developed comparisons of the properties of the carbonyl group and of the ethylene bond in αβ-unsaturated carbonyl compounds. He also formulated the accepted mechanism of the benzoin condensation. His interest in the relation between tautomeric change and aromatic and aliphatic substitution led to fundamental experiments on the halogenation of acetone and of carboxylic acids. The study of the effect of acids on enolization, and hence on halogenation, was followed by physico-chemical investigations on the catalytic activity of hydrogen ions, including consideration of the effect of adding water to acids in organic solvents. In 1909, at an early stage of this work, Lapworth was appointed senior lecturer in inorganic and physical chemistry and assistant director of the Inorganic Chemical Laboratories in the University of Manchester. His continuation of the work on ionization, together with lecturing requirements, gave him a grasp of thermodynamics which was an important element in his later thought.

Turning again to organic chemistry, Lapworth established a number of properties of sulphonic esters, contrasting their tendency to detachment of the alkyl group with that of carboxylic esters to reactions involving detachment of alkoxyl. In 1913 he was elected to the Royal Society and appointed to succeed W. H. Perkin, junior, as professor of organic chemistry in Manchester. The war of 1914–18 soon interrupted publications, except for a small group on the constituents of brain tissue and the pungent principles of ginger.

In 1920 Lapworth published his principle of alternate polarities. In this he focused attention on the polar properties induced in aliphatic and aromatic compounds by substitution, as shown by the study of the characteristic activity of the various atoms in molecules of both types. He also emphasized how unsatisfactory were the terms 'electronegative' and 'electropositive' as applied to groupings in organic molecules, and stressed the significance of the classification of groups according to their general influence on acidic or basic properties of compounds. He developed these views later, based successful experiments on them and, partly by his publications such as those in 1922 but also by personal discussions, he helped in laying the foundations on which Robinson based a more general and clearer interpretation of these phenomena in electronic terms. Most valuable was his classification of reactants in organic reactions as anionoid and cationoid (1925), which fused conceptions of organic reactivity with those by which acids and oxidizing agents are recognized as electron acceptors, and bases and reducing agents as electron donors. The condensed nature of this publication and the renaming of these classes by Ingold eight years later should not obscure the fundamental nature of Lapworth's contribution.

Among his work on the subsequent developments of electronic conceptions one may notice particularly the recognition, in 1928, that the effect which was afterwards given a physical interpretation as resonance must be regarded as affecting the average molecules of the reactants, and that the polarizability of molecules was not an adequate explanation. These theoretical extensions were made in discussing further experimental studies of the cyanohydrin and other reactions.

In all this original work Lapworth's theoretical insight and his skill with simple experimental methods were combined with an extraordinary grasp of general chemistry. It was therefore natural that as a teacher, lecturing on physical, organic and general inorganic chemistry in succession, he should concern himself to an unusual degree with the exposition of ideas, methods and general principles, so that his lectures were most stimulating and valuable to his better students, though they might be the despair of some who wanted only the easy catalogue of information.

By taste and temperament Lapworth was a scholar and investigator rather than an administrator, but he was called to be director of the Chemistry Laboratories at Manchester for a dozen years. Throughout this period he had invaluable help from his wife in handling departmental details, and his own qualities brought to him the affection and full support of his colleagues. The first half of his period as director saw the fruitful collaboration between himself and Prof. (now Sir Robert) Robinson, whom the University was able to invite to become professor of organic chemistry in 1922 through Lapworth's ability to transfer from that chair to the inorganic and physical side. When Robinson went to London in 1928, Lapworth made his objective the development of the school of physical chemistry in Manchester to full stature, through the appointment of a professor of established reputation to a new chair in that branch of chemistry, while maintaining the traditional strength of the organic side of the department. During the five years which, as it transpired, were necessary to achieve this, he was responsible for the whole department and, with characteristic sacrifice of personal and temporary interests, he considered it necessary to maintain it on the most economical basis to provide for the maximum expansion of equipment and opportunity when he would be handing over. It will generally be agreed that with the appointments of Prof. I. M. Heilbron and Prof. M. Polanyi the object which he set himself, and which the University adopted, was fully achieved. But for the present war it would have been rounded off by a new building for physical chemistry, in addition to the re-equipping of the existing laboratories which his successors carried out.

After the severe strain of these years of responsibility, Lapworth's health, which was never robust, broke down, but a period of rest and care enabled him to enjoy again the visits of his friends and some of the many hobbies and recreations which he had cultivated with remarkable skill and thoroughness. Music had run through his whole life. He had represented the University on the council of the Royal Manchester College of Music for more than twenty years. His taste was thoroughly sound, and he played the violin well and with great enjoyment. At his house one might have chamber music, or talk of fishing or of the arrival of migrant birds on an Easter holiday, or perhaps an exposition of microscopy or a wireless speciality, or reminiscences of mountaineering, or news of the latest from the theatre or the films—indeed the most diverse interests and lively comment. Many of his friends will retain pleasant memories of these occasions.

G. N. BURKHARDT.

Dr. R. T. Beatty

DR. RICHARD THOMAS BEATTY, whose death was announced recently, was a member of the Admiralty Scientific Staff and was born at Dungannon on April 26, 1882. He was educated at the Royal School, Dungannon, and Queen's University, Belfast, where he afterwards became lecturer in experimental physics.

Beatty worked for some years at the Cavendish Laboratory where he became interested in what were then known as homogeneous or characteristic X-rays. He was exciting this radiation and the associated secondary electrons and making a number of pioneer observations in this field. These observations were among those which helped to lay the experimental foundations of the quantum idea which was only then beginning to take shape. Between 1907 and 1920 he published a number of papers, mainly in the *Philosophical Magazine* and the *Proceedings of the Royal Society*, on this and related subjects.

Beatty served at the Admiralty in a temporary capacity in the War of 1914–18, and was engaged in research work at Portsmouth. In 1920 he joined the permanent scientific staff of the Admiralty.

WE regret to announce the following deaths:

Squadron-Leader J. O. Hinks, formerly Armourers and Brasiers' research fellow in aeronautics at Cambridge, on active service, aged twenty-nine.

Prof. W. Vogt, professor of anatomy in the University of Munich, noted for his work on the embryology of the Amphibia, on March 17.

NEWS AND VIEWS

The King's Birthday Honours

The following names of scientific men and others associated with scientific work appear in the King's Birthday Honours List:

Baron: Prof. F. A. Lindemann, personal assistant to the Prime Minister, professor of experimental philosophy, Oxford.

G.B.E.: Viscount Nuffield.

K.C.B.: Sir George Gater, permanent Under-Secretary of State for the Colonies and secretary, Ministry of Home Security, formerly clerk and education officer to the London County Council.

K.C.M.G.: Mr. Frank Gill, for services in development of the telephone industry and of international telephony; Dr. H. H. Scott, director of the Bureau of Hygiene and Tropical Diseases, London.

Knights Bachelor: Col. A. S. Angwin, Engineer-in-Chief, General Post Office; Mr. R. W. Gillespie, a founder of the Fairbridge Farm Schools in Australia; Prof. J. P. V. Madsen, professor of electrical engineering, University of Sydney, and chairman of the Radio Research Board, Australia; Dr. P. H. Manson-Bahr, for services to tropical medicine and as consulting physician to the Colonial Office; Mr. K. G. Mitchell, consulting engineer (roads), India; Mr. E. B. Pratt, managing director, Imperial Chemical Industries (India), Ltd.; Prof. J. B. S. Stopford, vice-chancellor, University of Manchester.

C.B.: Mr. C. A. Taylor, regional director, London Telecommunications, General Post Office; Mr. F. A. Whitaker, civil engineer in chief, Admiralty.

C.M.G.: The Hon. F. E. Harris, Minister of Agriculture and Lands, Minister of Supply, Industry, and Post-war Development, Southern Rhodesia; Dr. S. A. Neave, assistant director, Imperial Institute of Entomology; Dr. H. A. Tempany, agricultural adviser to the Secretary of State for the Colonies.

C.I.E.: Mr. W. Meiklejohn, senior conservator of forests, Bengal; Mr. C. F. C. Beeson, forest entomologist and conservator, Government of India.

C.B.E.: Prof. F. C. Bartlett, professor of experimental psychology in the University of Cambridge, and a member of the Flying Personnel Research Committee; Maj. G. P. Bulman, director of engine development and production, Ministry of Aircraft Production; Mr. W. Deacon, president of the Pharmaceutical Society of Great Britain; Mr. W. A. Elder, principal veterinary and agricultural officer, Swaziland; Mr. R. H. Franklin, assistant secretary, Ministry of Agriculture and Fisheries; Dr. J. A. Glover, lately senior medical officer, Board of Education; Mr. P. Good, deputy director, British Standards Institution; Mr. M. T. Tudsbery, civil engineer to the British Broadcasting Corporation; Dr. R. Wilson, Commonwealth statistician and economic adviser to the Treasury, Australia.

O.B.E.: Prof. J. F. Baker, professor of civil engineering, University of Bristol, and scientific adviser, Research and Experiments Branch, Ministry of Home Security; Lieut.-Col. T. H. Battye, director of statistics, Department of Supply, India; Mr. T. Beacall, an assistant comptroller, Patent Office; Dr. R. C. Bowden, assistant director, Ordnance Factories, Ministry of Supply; Prof. T. H. Davey, director, Sir Alfred Lewis Jones Research Laboratory, Sierra Leone; Dr. A. G. Francis, deputy Government chemist; Mr. E. E. L. Grundy, Principal, Technical School, Jamalpur; Mr. J. B. Nevitt, general manager, Ammunition Dept., Imperial Chemical Industry (Metals), Limited; Dr. S. J. Saint, director of agriculture, Barbados; Maj. L. Sealey-King, district officer, Nigeria; Khan Bahadur Maulvi Zafar Hasan, lately Superintendent, Archæological Survey, Northern Circle, Agra.

M.B.E.: Lala Kundan Lal Aggarwal, deputy conservator of forests, Punjab; Mr. L. C. Giles, assistant district officer, Nigeria; Mr. P. W. Harris, district officer, Kenya; Mr. J. T. Kennedy, senior assistant livestock officer, Uganda; Mr. P. E. Keam, Council for Scientific and Industrial Research, Australia; Sohan Lal, principal, School of Engineering, Orissa; Mr. K. W. Switzer, district officer, Nyasaland.

I.S.O.: Mr. J. L. Oliver, lately a native commissioner, Southern Rhodesia; Lieut.-Colonel F. J. Wane, for services as a native commissioner in Southern Rhodesia; Mr. S. B. Williams, district commissioner, Swaziland; Mr. S. B. Brewer, head of the Technical School Section, Board of Education; Mr. H. Chambers, principal, Ministry of Agriculture and Fisheries; Mr. J. Getty, chief inspector, Ministry of Agriculture, Northern Ireland.

> On the outbreak of war, it was obvious that restrictions would have to be imposed on the use of paper. By adopting a slightly thinner paper, and the curtailment or omission of certain sections of Nature, it has been possible to retain its more important features. Further reductions in size are now being imposed, but every effort will be made to ensure that no vital characteristic of the journal is impaired.
>
> The publishers regret to have to announce that, on account of increased costs, the price of Nature as from and including the issue of July 5 will be 1*s.* 6*d.*

Prof. F. A. Lindemann, F.R.S.

All who know Prof. F. A. Lindemann, professor of experimental philosophy in the University of Oxford, will be glad that the King has conferred the honour of a barony on him. Prof. Lindemann is one of the few men of science to rise to a position of influence in affairs in our time and quite possibly the youngest man of science ever to be elevated to the House of Lords. Those who profess to see in him merely "the man of mystery behind Churchill" or who laud him as the inventor of everything or depreciate him as the thwarter of all good schemes, do injustice to a man of great personality and remarkable parts. At the Prime Minister's right hand he is peculiarly well placed. His foresight, his wide knowledge of the scientific problems that the age and the War have brought forth, his great ingenuity, never more acutely shown than when difficulties are greatest, and his abundant courage, are, perhaps, his most serviceable qualities. There is one other quality, however, of great importance. Prof. Lindemann has a knowledge of the mentality of the French and Germans (he was educated at Darmstadt, Berlin and Paris) which few of the Government advisers could have and more 'realistic' than official advisers or diplomats seem to have had. This Continental experience of his, no less than his scientific insight and personal gifts, should stand him in good stead as a member of the Upper House, and in his present responsible position.

The Right Hon. Winston Churchill, F.R.S.

A unique ceremony took place in the Cabinet Room at 10 Downing Street on June 12, when the President of the Royal Society, Sir Henry Dale, admitted the Prime Minister into the fellowship of the Society. Among those present were the Society's biological secretary, Prof. A. V. Hill, M.P., the physical secretary, Prof. A. C. G. Egerton, the foreign secretary, Sir Henry Tizard, and the assistant secretary, Mr. John D. Griffith Davies. After the Prime Minister had signed his name in the ancient Charter Book, Sir Henry Dale showed him the signature of his ancestor, Sir Winston Churchill, father of the great Duke of Marlborough, who was one of the early fellows of the Society, having been admitted into the fellowship in 1664.

The Union Observatory, Johannesburg

The Union Astronomer, Dr. H. E. Wood, director of the Union Observatory, Johannesburg, retired on February 3. Dr. Wood, who was educated at the University of Manchester, was appointed assistant at the Transvaal Observatory, under the directorship of the late Dr. R. T. A. Innes in 1908. The work of that Observatory had been largely meteorological, of a routine nature, but after the appointment of Dr. Innes as director, the astronomical work was developed, new instrumental equipment was obtained and the Observatory—the name of which was changed to the Union Observatory in 1912—became one of the most important in the southern hemisphere. Dr. Wood succeeded Dr. Innes as Union Astronomer, on the latter's retirement in 1927. He has been particularly interested in the observation of minor planets and comets; he discovered many new minor planets and computed many orbits of minor planets and comets. Dr. Wood has also been an assiduous observer of occultations of stars by the moon, and the large number of occultations observed at the Union Observatory for many years has been of the greatest value in the study of the moon's motion. Dr. Wood has been closely associated with the South African Association for the Advancement of Science, of which he was for many years one of the secretaries and of which he was president in 1931.

Dr. H. E. Wood has been succeeded as Union Astronomer by Dr. van den Bos, who started his astronomical career as an assistant at the Leyden Observatory. A scheme of co-operation between the Union Observatory and the Leyden Observatory had been arranged, under which the Leyden Observatory—which has a large staff but poor observing conditions—should station one member of its staff at the Union Observatory—which has a small staff but good observing conditions—to whom all necessary facilities should be offered. Under this scheme Dr. van den Bos, whose primary interest is double-star observation, went to Johannesburg in 1926 to make observations of double stars with the large 26½-in. visual refractor. In 1927 he was transferred to the staff of the Union Observatory, becoming chief assistant in succession to Dr. Wood, on his appointment as Union Astronomer. Dr. van den Bos is not only an assiduous and accurate double-star observer but has also computed many double star orbits. With the collaboration between Dr. van den Bos and Mr. Finsen, one of his assistants, the Union Observatory is now making a more important contribution than any other observatory to double star astronomy. Among interesting observations made by Dr. van den Bos and Mr. Finsen have been the apparent triplicity of Nova Pictoris, a few years after its outburst, the three nuclei showing a progressively increasing separation; also the figure-of-eight appearance of the asteroid Eros at the 1931 opposition, which rotated in the period of the variation of brightness of Eros.

U.S. National Academy of Sciences: Recent Elections

At the annual meeting of the U.S. National Academy of Sciences, recently held at Washington, the following were elected foreign associates: Prof. E. D. Adrian, professor of physiology in the University of Cambridge; Prof. A. V. Hill, secretary of the Royal Society and Foulerton research professor (Nature, May 10, p. 573); Sir Arthur Keith, formerly Hunterian professor of the Royal College of Surgeons (Nature, May 24, p. 639).

The following American men of science were elected to membership: Prof. W. E. Bachmann, associate professor of chemistry in the University of Michigan; Dr. R. J. Dubos, associate in bacteriology in the Rockefeller Institute for Medical Research; Prof. E. A. Graham, professor of medicine in Washington University (St. Louis); Dr. A. S. King, superintendent of the physical laboratory, Mount

Wilson Observatory; Prof. C. C. Lauritsen, professor of physics in the California Institute of Technology; Dr. A. L. Loomis, director of the Loomis Laboratories, Tuxedo Park, N.Y. (physics); Prof. J. R. Oppenheimer, professor of physics in the University of California; Prof. J. T. Patterson, director of zoological research in the University of Texas; Prof. Karl Sax, professor of botany in Harvard University; Dr. G. G. Simpson, associate curator of vetebrate palæontology in the American Museum of Natural History; Dr. Joseph Slepian, Westinghouse Electric and Manufacturing Company (electrical engineering); Dr. L. F. Small, National Institute of Health (organic chemistry); Dr. W. M. Stanley, associate member in biophysics of the Rockefeller Institute for Medical Research; Prof. T. Y. Thomas, professor of mathematics in the University of California at Los Angeles; Prof. G. B. Wislocki, Parkman professor of anatomy in Harvard University.

University College, Nottingham: Air-Raid Damage

NOTTINGHAM University College buildings in Shakespeare Street have been damaged by a high explosive bomb of heavy calibre. The Departments of Mining and Textiles occupy the Shakespeare Street buildings. The Faculties of Arts and Pure Science and the Departments of Engineering are housed in University Park buildings. The main damage was confined to the west wing of the building, the principal lecture theatres and laboratories, though seriously damaged, escaping destruction. The Mining and Fuels Department was almost completely destroyed, including practically the whole of its valuable apparatus.

In the Textiles Department, which was housed in that section of the building formerly occupied by the Natural History Museum until it was transferred to Wollaton Hall, some of the hosiery machinery was salvaged, but much damage was done to the general structure of that part of the building. Blast broke windows, removed doors and blew down plaster, etc., in practically all parts of the building.

German Aircraft Design

TECHNICAL details now available of the new German fighter, Messerschmitt 109*F*, indicate the general trend of enemy aircraft design towards high altitude operation. The machine, a modification of earlier Messerschmitt fighters, is clearly designed not only to reach great heights, but also to retain climb and general manœuvrability at those altitudes, without which the operation of air fighting is at a tactical disadvantage. It is claimed that this design has a service ceiling of 38,000 ft., but the attainment of this height alone has little advantage, it being necessary to retain a speed of manœuvre better than the opposing aircraft, for fighting purposes.

The wing area has been increased, an alteration necessary for this effect, but disadvantageous in many other respects. The amount of armament has been decreased to one cannon and two machine guns. Weight reduction is also an advantage for high altitude work, but a lessening of fire power has obvious drawbacks in a fighter. All guns are now enclosed in the body, the outboard ones on the wings being discarded. The concentration of weight nearer the centre of the machine would improve the quickness of the response to lateral control. Possibly it also reduces the weight and complication of the arrangement for heating the guns, as they would be nearer to the engine, the most convenient source of heat available. It is essential in high altitude flying to prevent freezing up of guns, while they are not in action, by some externally applied heat.

Engineering Economy and Æsthetics

THE Council of the Institution of Civil Engineers has recently given consideration to the need to foster among engineers the closer study of: (*a*) the economics of engineering projects; (*b*) the organization and management of engineering work; and (*c*) the relations of æsthetic considerations to engineering design and construction. It is believed that in the period of reconstruction and development which will follow the War these subjects will become of increasing importance, and in the national interest should form a part of the equipment with which engineers should be furnished in order that they may adequately play their part in the task before them. The Council accordingly intends to examine all possible means by which the Institution can influence the better understanding of engineering economics and æsthetics, not only by students resident at the universities, but also by those otherwise engaged in their engineering training, so that eventually a study of these subjects may form an integral part in the recognized education of all engineers.

As a beginning, the Council of the Institution approached the University of Cambridge with an offer to finance for a period of five years a lectureship on the subjects envisaged in the hope that they would in due course form part of the engineering curriculum of the Mechanical Sciences Tripos. The proposal was cordially welcomed, and has now been accepted in principle by the Council of the Senate of the University; but its full adoption will necessitate some reconsideration of the scheme of instruction in the Engineering School and possibly of the Mechanical Sciences Tripos, which it would be impracticable to undertake in war-time. Nevertheless, during the next academical year, a number of eminent engineers and others will be invited to visit the University to give either single lectures or short courses on subjects coming within the terms of the proposal.

Foreign Periodicals in War-time

THE Association of Special Libraries and Information Bureaux is undertaking a survey in Great Britain of the present position in regard particularly to enemy and enemy-controlled publications, especially the current issues of periodicals. Previous explanatory surveys have confirmed the impression that since the early part of 1940 only very limited supplies of such publications have been arriving in Great Britain; that they consist mainly of imperfect sets of a relatively few periodicals restricted very largely to departmental libraries that are not accessible to the general public; and that there is widespread dissatisfaction and a sense of frustration among students and intellectual workers generally as well as among research workers and technologists intimately associated with the war effort. Nothing short of a fully representative, detailed and documented survey can reveal the inadequacy of the present supplies. Through the good offices of the Royal Society, the Rockefeller Foundation has provided funds for the conduct of a rapid, extensive survey of this character.

The survey will be made by a Committee of the Association and will be completed by the autumn. A memorandum is being circulated to some two thousand institutions and individuals to ascertain what publications they need and the extent to which they are locally available. In the interim, endeavours will be made to facilitate the distribution of available supplies, but the primary objective is to obtain a detailed inventory of needs and to ascertain what further supplies are essential to meet demands. Those interested should communicate with the ASLIB Foreign Periodicals Committee, 31 Museum Street, London, W.C.1.

Medicinal Herbs

THE Committee recently appointed by the Ministry of Health to consider what steps should be taken to secure organization of cultivation and collection of vegetable drugs has presented an interim report. The committee, of which the chairman is Sir Weldon Dalrymple-Champneys, considers that, so far as domestic production is concerned, attention should be concentrated on the following: Agar, dill, belladonna, Irish moss, colchicum, digitalis, ergot, male fern, liquorice, henbane, peppermint, psyllium, sphagnum, stramonium, dandelion and valerian. The committee is thus in agreement with the recommendations of the Medical Research Council, which advised, in M.R.C. War Memorandum No. 3, that all these drugs, with the exception of agar, should be produced in the United Kingdom; with regard to agar, the M.R.C. Memorandum recommended that its production should be encouraged in the British Empire overseas. Concerning the collection of herbs which grow wild, the report of the committee of the Ministry of Health states that steps have already been taken to encourage it on methodical lines, and commends the efforts of the Boy Scouts Association in this direction; the Association has circulated a pamphlet giving details of identification, methods of collecting, drying and dispatch, in respect of several vegetable drugs and has arranged that the trade will purchase the collections so made. The Royal Botanic Gardens, Kew, have conferred with the National Association of Women's Institutes to organize the collection of important herbs in each county, the selection of the herbs to be determined by their local abundance.

State Laboratory of Eire

THE report of the State Chemist of Eire upon the work of the State Laboratory for the year ending March 31, 1941, has been issued in typescript form. The Laboratory carries out chemical work for all departments of the Government of Eire, the greater portion being performed in the Laboratory in Upper Merrion Street, Dublin, but samples of wines, spirits and tea are also examined at the chemical station in the Custom House, Cork. The total number of samples examined in the course of the year, including those dealt with at Cork, was 29,571, as compared with 37,843 in the preceding year, a decrease of 8,272. Of this figure, 531 samples represent the decrease at Cork Chemical Station. The decrease in the number of samples examined was mainly in respect of those received for the Revenue Commissioners and the Department of Agriculture and Fisheries. There was a large fall in customs import samples, particularly in regard to wines and spirits; the fall in the number of samples received from the Department of Agriculture and Fisheries was due to the impossibility of obtaining dairy instruments from the Continent and the cessation of sea water sampling. Increases were registered in respect of 'wrecked goods', and additional samples of feeding stuffs were examined in order to control any possibility of adulteration due to shortage in supplies. The development of the Milk and Dairies (Special Designations) Regulations led to an increased number of tests being carried out for the Department of Local Government and Public Health. The introduction of the phosphatase test has enabled close control of pasteurization to be achieved; investigation of plants yielding milk failing on this test has always revealed defects corresponding to the result of the test. A variety of specimens has been examined for the Department of Justice during the year.

Trichinosis in Britain

AT a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on May 22, Dr. P. B. Beeson, of Harvard University, read a paper on factors influencing the prevalence of trichinosis in man. He said that few cases of trichinosis have been recognized in Great Britain until recently, although the disease occurs fairly commonly in Europe and the United States. Within the past few months, however, several outbreaks have been reported in different parts of England and Wales, which have evoked a new interest in the clinical and epidemiological aspects of the disease. Since human trichinosis is nearly always acquired by eating pork, knowledge of the ways in which swine become infested is important. In the United States, where 0·5–5·0 per cent of swine has trichinosis, the chief factor responsible is the practice of feeding swine on uncooked garbage. In Great Britain there is little opportunity for this means of swine infestation to take place, and the probability is that the rare cases of swine trichinosis which occur in this country are acquired by eating infested rats. Trichinosis has been found in rats in several parts of Great Britain.

Locally manufactured sausages appeared to have been the meat responsible for the recent epidemics of human trichinosis in Great Britain. In explanation of the large number of people involved in some of these epidemics, it was pointed out that rationing of meat and changes in the composition of sausages have brought about a condition whereby an unusually large number of people eat the meat of a single animal. Furthermore, in view of the fact that a partially protective immunity develops after one attack of trichinosis, comparative susceptibility of the British population might have led to the development of more clinical cases than would have resulted from similar exposure of a previously exposed population. The measures indicated for prevention of the disease are destruction of rats and education of the public about the danger of eating raw or undercooked pork.

Announcements

SIR D'ARCY THOMPSON, professor of natural history in the University of St. Andrews, has been elected a member of the American Philosophical Society.

PROF. R. W. WOOD, research professor of experimental physics in Johns Hopkins University, has been awarded the Henry Draper Medal of the U.S. National Academy of Sciences "in recognition of his contributions to astronomical physics".

DR. MAX NONNE, professor of neurology at the University of Hamburg, has recently been awarded the Goethe Medal for Art and Science on the occasion of his eightieth birthday.

PROF. OTTO HAHN, director of the Kaiser Wilhelm Institute for Chemistry, Berlin-Dahlem, has been awarded the Copernicus prize for 1941, by the University of Königsberg for his work on radioactivity.

PROF. JACQUES ERRERA, formerly professor of physical chemistry in the University of Brussels, has been appointed manager of the Research and Control Division of Sidney Blumenthal and Company at Shelton, Conn.

MISS J. P. STRACHEY will retire shortly from the principalship of Newnham College, Cambridge, which she has held since 1923, and the fellows of the College have elected as her successor Miss Myra Curtis, associate and fellow of the College and principal assistant secretary to the War Damage Commission.

THE late Sir Charles Clifford by his will left a share of his residuary estate to the University of Sheffield. Since the death of Lady Clifford on May 1, the residuary estate falls to be divided between the beneficiaries. It is expected that the University will receive upwards of £50,000, after duties have been paid.

The following appointments have recently been made: Dr. V. M. Conway, assistant lecturer; Dr. L. Leyton and Mr. A. N. Barker, temporary demonstrators; Mrs. E. M. Harrison, part-time assistant in the Department of Botany.

AT the annual general meeting of the Institute of Physics held on June 4, the following were elected to take office on October 1, 1941: *President*, Sir Lawrence Bragg; *Vice-President*, Prof. W. Makower; *Honorary Treasurer*, Major C. E. S. Phillips; *Honorary Sercetary*, Prof. J. A. Crowther; *Ordinary Members of the Board*, Prof. J. Chadwick and Mr. D. C. Gall.

AT the annual general meeting of the Marine Biological Association of the United Kingdom, Dr. George Parker Bidder was re-elected president. The list of officers and vice-presidents also remains unchanged. As new members of Council, Dr. C. F. A. Pantin, Prof. T. A. Stephenson, Prof. W. M. Tattersall, Prof. C. M. Yonge and Mr. J. Z. Young were elected.

MR. R. S. HUDSON, Minister of Agriculture, has announced the appointment of an Agricultural Improvement Council for England and Wales, to devise methods for seeing that promising results of research are brought as rapidly as possible into ordinary farming practice. The Council will advise from time to time on agricultural problems that seem to need scientific investigation. It will consist of a chairman and twelve members, appointed for three years with the possibility of re-appointment, and will include practical farmers as well as distinguished men of science.

THE Bernard Baron Trustees have offered the Royal College of Surgeons £40,000 to endow a Bernard Baron research professorship at the College. In a letter making the offer, the Trustees state that they appreciate that a large part of the resources of the College will have to be devoted to the erection of new buildings and the assembling of new collections to replace the damage done to the College during air raids, and they have made the offer of a research professorship in order that research being carried out at the College may not suffer. The laboratories at the College provided by the Trustees fortunately have not been damaged structurally, and the valuable equipment they contained had been removed to improvised accommodation in the country.

A NINTH Summer Conference on Spectroscopy and its Applications will be held at the Massachusetts Institute of Technology during July 21–23. The conference will repeat to a considerable extent the type of programme presented at the conferences held during the past eight summers. The early sessions will be devoted principally to applications of spectroscopy to the analysis of materials. Other topics to be considered are absorption spectrophotometry, photographic photometry, biological and chemical effects of spectral radiation, industrial applications of spectroscopy, analysis of spectra and the measurement of wave-lengths. Further information can be obtained from Prof. G. R. Harrison, Massachusetts Institute of Technology, Cambridge, Massachusetts.

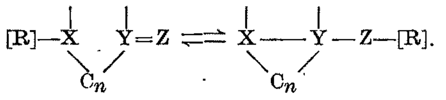
LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. They cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.*

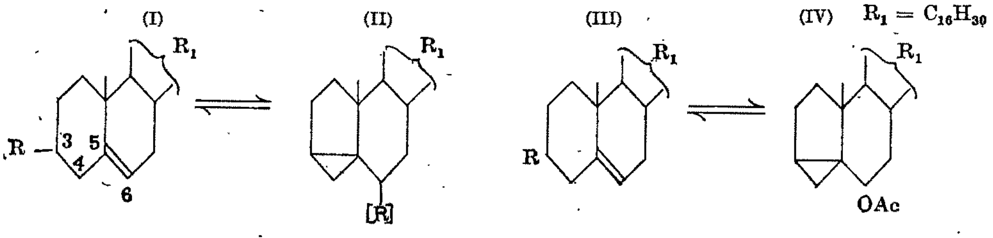
In the present circumstances, proofs of "Letters" will not be submitted to correspondents outside Great Britain.

Pentacyclic Steroids

The arrangement of carbon atoms indicated by X, Y and Z in the following scheme is contained in many unsaturated steroids and constitutes a potential tautomeric system according to the general scheme

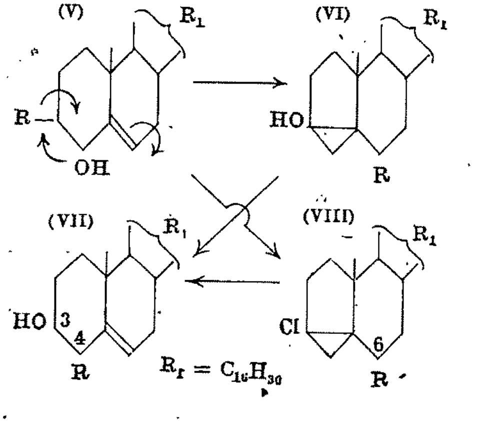


As the carbon atoms concerned (3, 5 and 6 in I) are components of a cyclic system, being members of ring A and B of the tetracyclic steroid ring system, the resulting tautomeric change would be a transannular one and involve the formation of a bridge-linkage from C_3 to C_5. Such an intramolecular rearrangement would therefore lead to a pentacyclic system as indicated in (II).



This transannular change has evidently occurred during the formation of *i*-cholesterol from cholesterol[1], for which so far no explanation has been offered: cholesteryl *p*-toluenesulphonate (III, R = *OTs*) is converted by an anionotropic change into *i*-cholesteryl acetate (IV). The reaction is reversible since cholesteryl acetate (III, R = *OAc*) is easily obtained from (IV).

In studying the puzzling reactions of the unsaturated α-glycol, *cis*-3 : 4-Δ^5-cholestene diol[2], we have now found that transannular rearrangements of the above type offer a rational interpretation of the observed facts. The two possible monoesters of the glycol have been obtained by various methods and the position of their esterified OH group has been established. The 3-monoesters (V, R = *OAc*, *OBz*, etc.) result *inter alia* from the action of acyl- or aryl-chlorides on the diol, whilst the 4-monoesters (VII) are smoothly formed at room temperature by the interaction of cholesteryl dibromide with the silver salts of the respective acids in pyridine solution as well as from cholesteryl esters and SeO_2 under well-defined conditions. The remarkable fact has also been established that an acyl migration from C_3 to C_4 occurs when the aliphatic 3-monoesters are warmed to 90° in acetic acid solution. This novel reaction, which has no analogy in the steroid series, becomes intelligible on the assumption of an intramolecular rearrangement and the intermediate formation of the labile pentacyclic compound (VI). Rupture of the bridge linkage, followed by the allylic change usual in these compounds then leads to VII.



The same mechanism accounts for the unexplained migration of a benzoyl group from C_3 to C_4 in the 3-benzoate of 6-chloro-Δ^4-cholestene[3]. This substance is obtained from the 3-monobenzoate of the *cis*-diol (V, R = *OBz*) by the action of $SOCl_2$ and, reacting in the tautomeric form (VIII, R = *OBz*) yields the 4-monobenzoate (VII, R = *OBz*) on replacement of Cl by OH.

An alternative mechanism of acyl migration, involving the formation of ortho-carbonic esters as intermediates, will be discussed in the detailed account of this work.

Further, there is evidence in the literature of the sex hormones that pentacyclic steroids may occur as normal or pathological metabolic products of the animal organism. Two derivatives of this type, in the androstane and pregnane series respectively, are known as laboratory products[4]. The bridge-linkage in these substances is easily broken by contact with dilute HCl at room temperature. The resulting product in the androstane series is 3-chloro-dehydroandrosterone, a substance which has frequently been isolated from normal and pathological urines. In urine it originates obviously from a labile precursor, during the usual preliminary hydrolysis with dilute HCl in the isolation procedure. The ease of its formation seems to indicate this precursor to be a 6-monoester of *i*-dehydroandrosterone, which, owing to its lability, has so far escaped isolation (cf. also 3 : 5-androstadienone[5] and other substances isolated from the urine of adrenal tumour cases[6]).

Experimental details of this work will be published elsewhere as soon as circumstances allow, in conjunction with Dr. V. A. Petrow and Mr. W. W. Starling. Work on analogous rearrangements in ring B of the steroids is in progress.

Correlation between Sex-, Thyroid- and Adrenal Cortical Hormones

EXPERIMENTS were performed on 168 adult gonadectomized male and female rats. The following hormones were administered, the figures representing the dose given per week: androsterone 4·5 mgm., testosterone propionate 0·75 mgm., œstradiol benzoate-butyrate 0·015 and 0·09 mgm., desoxycorticosterone acetate 2–4 mgm. (also tablets of this hormone were implanted subcutaneously), desiccated thyroid powder 90–480 mgm., thyroxine sodium 1–3 mgm.

A co-operative stimulating effect on the weight and size of the organs was recorded between œstrogenic and thyroid hormones in the case of female sex organs, liver, kidneys and (less definitely) heart and spleen. Hypertrophy of the adrenals was also greater with these two hormones than with either hormone alone.

A similar stimulating co-operative effect was noticed between the male sex hormone androsterone and thyroid hormones in females, or desoxycorticosterone and thyroid hormones on the weight and size of liver, kidneys, heart and, less constantly, spleen, but not on sex organs.

Desoxycorticosterone, when injected alone, produced only a slight increase in weight of kidney and liver.

The following changes in weights of organs illustrate some of the above statements. In control ovariectomized rats' average weights were as follows: liver 7·22 gm., kidneys 1·53 gm. and heart 0·828 gm. The respective weights in rats treated with a large dose of thyroid hormones were 9·53, 2·41 and 1·158 gm.; in rats, receiving androsterone and thyroid hormones 10·75, 2·44 and 1·345 gm.; in rats receiving oestrogenic and thyroid hormones 13·2, 2·98 and 1·383 gm., while in rats receiving oestrogen alone 9·03, 1·79 and 0·921 gm.

On the other hand, the hypertrophy of the adrenals and the retardation of body growth produced by thyroid hormones was decreased when male hormones were administered simultaneously, the latter exerting a partial neutralizing (antagonistic) action on these effects of thyroid hormones.

Blackening of Potato Tubers on Boiling

IT has been shown that the black coloration which appears in some potato tubers after boiling cannot be melanin, as the colour disappears rapidly in acid solution at about *p*H 3·0; at this *p*H melanin is quite stable. The bleached pigment appears to be soluble in acid solution, but the grey coloration partially reappears on neutralizing the acid with buffer solution at *p*H 7·0. No correlation was observed between the development of the pigment and the activity of the enzyme tyrosinase as estimated by the Warburg technique. Neither could any correlation be found between the blackening and the tyrosine content of the potatoes. It was observed that among the varieties tested there appeared to be two distinct levels of tyrosine content: King Edward and Majestic with 40–60 mgm. per 100 gm. fresh weight, and Kerr's Pink and Arran Banner with 8–25 mgm.

The pigment was found to develop as well after heating in alcohol as in water, but in neither case did it appear until oxygen was admitted. The pigment and its colourless precursor were both insoluble in 60 per cent alcohol. As shown by the unpublished work of Pearse, pieces of potato 1 cm. thick require a minimum of two minutes boiling for any black colour to develop, and for full coloration a total of five minutes is required, although this can be spread over several separate periods.

Attempts to isolate the grey pigment from boiled potato failed, but led to the suspicion that the pigment might be an iron compound. Estimation of the iron content of a large number of tubers showed a marked correlation between iron content (as extracted by 20 per cent sulphuric acid) and the incidence of blackening in tubers drawn from the same sample; blackening tubers contained in every case more iron than the normal ones. The correlation was not so clear when comparison was made between tubers from different samples, but on this point further work is required.

Nearly the whole of the extractable iron in the tubers appeared to be in the ferrous state. No reliable results for total iron could be obtained by micro-incineration of the material in acid as a very considerable exchange of iron was found to take place between the solutions and the glass of the incineration tubes. The evidence suggested, however, that under the conditions employed the whole or nearly the whole of the iron was extracted by the acid.

It was found that non-blackening tubers could be made to blacken by soaking for some days in 1 per cent ferrous sulphate, washing away the excess and boiling. On exposure to air they developed a very dark greenish-black colour, similar to that found in ordinary blackening tubers, but more intense; this pigment also was rapidly bleached at *p*H 3·0. It was also observed that white ferrous hydroxide, precipitated from solution, gradually oxidized, passing through green to the magnetic black oxide.

This work, carried out during 1936–39 with the help of a grant from the Potato Marketing Board, had to be interrupted at the outbreak of war. Though much remains to be done it is suggested, as a tentative hypothesis, that in the raw tubers the precursor of the black pigment exists in the form of ferrous iron bound in a loose complex, possibly in combination with proteins. This complex is hydrolysed on boiling and the iron is then precipitated as a colourless ferrous compound, probably the hydroxide, which is gradually oxidized to the black oxide as air penetrates to the tissues. Although as yet supported by no direct evidence, this theory fits not only the facts established in the present work but also a number of hitherto unrelated observations of other workers in the same field, such as that of Tinckler[1] that the black pigmentation was induced in normal potatoes by contact with rusting iron during boiling, and the evidence obtained by Ross and Tottingham[2] that the proteins of blackening potatoes are more easily hydrolysable and autolysable than those of normal tubers.

I should like to thank Prof. V. H. Blackman for his advice and criticism throughout the course of this work.

Plagiophyres in an Intrusion at Downpatrick

IN 1937 B. C. King[1], in a petrographical examination of some Caledonian hypabyssal rocks from Kirkcudbrightshire, recorded the occurrence of plagiophyres in the dyke assemblage of this area.

Recent examination of a small intrusion at Slievenagriddle, two miles east of Downpatrick in Northern Ireland, has resulted in the discovery of this rock-type in the hypabyssal phase of the Newry 'granite' mass. The intrusion was originally recorded by the Geological Survey of Ireland[2], and on macroscopic examination was described by the Survey as syenite. In thin section the rock is seen to correspond closely to the Scottish plagiophyres; mafic minerals being entirely represented by chlorite, felspar and albite-oligoclase, abundant secondary calcite, etc.

Dykes of this Irish suite have been described from the Ards Peninsula[3] and the Killough-Ardglass coast[4], and are dominantly lamprophyric in these two areas. It is probable that further examination of this dyke-swarm towards the south-west (and the Newry 'granite') will reveal a more extensive variety of rock types than are at present known from the County Down area.

Specific Heat of β-Brass

MY previous theoretical work[1], based on a method of approximation, has been criticized by Bethe and Kirkwood[2]. I have now carried out a rigorous evaluation of the partition function at constant volume, starting first with the two dimensional quadratic lattice.

Three partition functions are calculated successively, namely, $P(1)$, $P(n)$ and $P(n^2)$ which refer to: a square of four atoms, the 'elementary cell'; a ladder consisting of n elementary cells joining in one dimension; and the whole lattice, which consists of n ladders joined together with their lath.

$P(1)$ is a sum of eight terms according to the eight possible configurations of the cell. In order to account for the statistical correlations of the cells (the long-range order effect), the terms of $P(1)$ are considered to be the coefficients of a certain quadratic form in two variables and $P(n)$ to be the n-fold iterated quadratic form. Similarly, the terms of $P(n)$ are considered to be the coefficients of a quadratic form in 2^n variables and the n-fold iterated form to be equal to $P(n^2)$. In these calculations the form in a large number of variables is reduced to a product of forms in two variables.

In the limit, $n \to \infty$, $P(n^2)$ is found to be equal to $[p(x, y)]^{n^2}$ where $y = x = \exp(-\varphi/kT)$ and φ is a constant of the dimension of an energy. The mean energy is equal to $\varphi y \partial \log p/\partial y$. The function $p(x, y)$ has the following form:

$$p(x, y) = \tfrac{1}{2}\{(1 + y)[(1 - x^2)^2 + 8x^2(1 + y) + (1 - x^2)\sqrt{1 + 14x^2 + x^4}] + \sqrt{2}[(1 - x^2)^4(1 - y)^2 + 32x^4(1 + 14y^2 + y^4) + 8x^2(1 - x^2)^2(2 - 3y + 8y^2 + y^3) + ((1 - x^2)^3(1 - y)^2 + 8x^2(1 - x^2)(1 - y + 7y^2 + y^3))\sqrt{1 + 14x^2 + x^4}]^{1/2}\} \cdot [(1 + 14x^2 + x^4) + (1 - x^2)\sqrt{1 + 14x^2 + x^4}]^{-1}.$$

It is independent of n and has no singularity. The specific heat curve has a broad maximum which has no resemblance to a λ-point.

The method applies to a lattice in three dimensions, and calculations are in progress.

Metallic Triazine Complexes

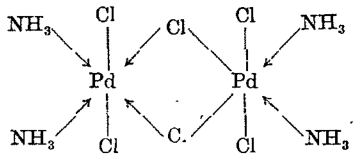
IN a recent note[1] referring to the palladium derivatives of diazoaminobenzene and of 4:4′-dimethyl-diazoaminobenzene described by Dwyer[2], it was stated that these compounds, containing one palladium atom united to three diazoaminobenzene units, "appear to be the first examples of hexacovalent palladous compounds [to be] described", this statement being made also by Dwyer in his original paper.

Actually, however, I have described the first such compounds[3], having prepared both platinous and palladous salts of αβγ-triamino-propane, the palladous derivative having the formula

$$[\{NH_2CH_2CH(NH_2)CH_2NH_2\}_2Pd]I_2.$$

Evidence was adduced to show that in such compounds all the amino-groups were coordinated to the metal, which was therefore undoubtedly hexacovalent.

Apart from this certain case, it is probable that the black crystalline compound[4] of empirical formula $(NH_3)_2PdCl_3$ has the constitution shown, containing one hexacovalent palladous and one hexacovalent palladic atom, bridged by the two chlorine atoms[5]. In this case the compound would exist as a resonance hybrid, and this factor is probably intimately associated with the colour of the crystals.



Dr. Dwyer's paper contains many interesting points. It is particularly noteworthy that the *tris*-diazoaminobenzene-palladium readily lost a molecule of diazoaminobenzene, and that the *bis*-diazoaminobenzene-palladium so formed could not be converted back to the original *tris*-derivative. This is not unexpected. The *bis*-derivative, having undoubtedly the planar configuration, could not undergo simple union with a third molecule of diazoaminobenzene, since the latter molecule would be unable to span the 1 : 6 position of the potential hexacovalent octahedron. The union would therefore be a complex process leading to an unstable compound, and hence does not apparently occur. I have discussed other cases of this phenomenon elsewhere[6].

Textures of Clays

PROBABLY the best method of evaluating the texture of a clay is to slake it up with water or break it up into its component parts by some method such as alternate drying and slaking, and then to size by combined sieve and pipette or hydrometer analyses. If this in turn is combined with microscopic examination, the grain shapes can be determined and an accurate conception can be obtained of the grain size distribution. The more detailed this size analysis the more valuable it is. However, without the mineralogical composition, the picture of the structure and texture is very incomplete. To quote an extreme case, a kaolin consisting of particles 95 per cent less than 43 microns and the main mineral, being kaolinite, may be only slightly plastic, whereas another clay having about 50 per cent of its particles less than 43 microns in diameter but containing water-swelling minerals of the montmorillonite group may be very plastic and have a very high modulus of rupture as well.

To take two examples, the mechanical analyses were as follows :

	1	2
Coarse sand	4·30	nil
Fine sand	24·80	1·23
Silt	35·60	37·90
Clay	28·80	61·12
Moisture	3·57	0·05
	97·07	100·30

1. Red clay from Port Elizabeth.
2. Washed kaolin from George, Cape Province.

At first glance one would be inclined to say that the second specimen would be the more plastic. Actually the kaolin is practically non-plastic although it is not hard and compact. The first sample contains some vermicular kaolinite, but is mainly composed of ferruginous clay minerals and illite. The second is composed almost wholely of kaolinite with some quartz. The kaolinite is platey and there is a high degree of coarse crystallinity. The first clay has a modulus of rupture of 390 lb./sq. in., whereas the value for the kaolin is less than 10 lb./sq. in.

Actually this type of analysis is not discriminating enough, and in later work the conventional size separates used by soil scientists was abandoned. The sub-sieve sizes were then dealt with in the following manner :—43–31, 31–16, 16–11, 11–5·5, 5·5–2·0, 2·0–1·0 microns, or as the texture of the clay varied. The method is flexible and the ultimate aim is to get the size distribution of the clay, rather than to fit the clay to a conventional nomenclature. If it is desired to compare the size distribution of two or more clays this can be best done graphically.

A problem that has not been solved is the condition of the organic phases[1]. The organic compounds are, with the exception of grass roots, etc., always associated with the finest sizes. That plasticity, green strength and other physical properties are influenced by the presence or absence of the peaty substances present in certain fireclays, kaolins and bog clays is evident from an examination of such rocks. In the case of a certain sedimentary kaolin, certain phases of the same clay contained organic matter and others did not. The difference in plasticity was striking.

Sense of Hearing in Fishes

I AM sure that the fish described in Dr. C. B. Williams' communication[1] did hear the bicycle bell, as a disturbance of the norm to which it is 'conditioned'. Dr. Bull has had to make a sound-proof room for his experiments at Cullercoats on the behaviour of blennies, etc.[2]

But the simplicity of the inner ear of fish, in which there is only an otolith floating in a saccule to serve instead of the graded tuning-forks of the mammalian cochlea, allows us to expect most fish to be rather hard of hearing, except in examples where we know to the contrary. The degree of hearing must vary from species to species, because the acoustic region of the brain shows varying degrees of development, even within one family ; and some fish have well-developed 'aids to the deaf' made from part of the swim bladder, for example, in carp and herring. All this, and more, is to be found in Dr. H. Muir Evans's recent book[3]. Dr. Evans's researches show that fishes have more elaborate organs of reception and perception than the text-books have led us to suppose. Sight, hearing and taste may all be well developed, and in varying degrees, and in a few species there is a genuine under-water voice.

RESEARCH ITEMS

Changes in Amputated Nerveless Limbs of Urodele Larvæ

O. E. Schotté and E. G. Butler described the above morphological changes in a paper read on April 29 at the annual meeting of the U.S. National Academy of Sciences. By repeated resections of the brachial plexus, fore-limbs of Urodele larvæ have been maintained in a nerveless condition for several weeks, and in some cases for as long as two months. A limb, completely devoid of spinal innervation, not only loses its capacity for regeneration, but also, after amputation, it undergoes radical morphological changes. Beginning at the level of amputation and proceeding proximally, structures of an amputated nerveless limb undergo regression and resorption. This structural regression brings about extreme reduction in size and eventually complete disappearance of the limb. Histological studies demonstrate that the regression is the result primarily of cellular dedifferentiation. All formed structures of the limb, including skeleton and muscles, go into extreme dedifferentiation and gradually disappear. Moreover, dedifferentiation in a nerveless limb involves not only those structures injured at the time of amputation, but also those remote from the amputation level. Articulations do not serve as barriers to the dedifferentiative processes. These radical morphological changes are not the result primarily of physiological atrophy, but represent alterations in the specific character of limb tissues, caused by the disturbed unrolling of regenerative processes. Since control experiments show that denervation alone only impedes further growth processes, but is not followed by regression of structures, the above results reveal the importance of amputation for the normal course of regeneration. Unamputated nerveless limbs exhibit no dedifferentiation; amputated nerveless limbs show extreme dedifferentiation and reduction, leading to eventual disappearance of the limb. The nervous system, therefore, formerly regarded as exerting primarily a trophic influence on cellular activities during regeneration, must now be considered as an important agent of the organism as a whole, enabling amputated limbs to carry on the complex cellular interactions for regeneration.

Field Properties of the Developing Frog's Egg

EXPERIMENTAL observations on these properties were described by H. S. Burr, on April 29, at the annual meeting of the U.S. National Academy of Sciences. Some six thousand determinations were made on fifty frogs' eggs prior to the development of the long axis of the embryo as seen in the appearance of the medullary plate. Potential differences between the vertex of the animal pole and four equidistant points on the equator of the egg were measured by the Burr–Lane–Nims technique. Three variations in the technique were employed and all were subjected to statistical analysis. From the very beginning it was apparent that at least one of the four points showed a significantly greater voltage drop from the vertex than any of the other three. This point was then marked either by staining by Nile Blue sulphate or by the establishment of orientation points in the immediate environment of the egg. Of the fifty embryos, ten were marked successfully and developed to the neural plate stage. In the remaining forty, correlations were either not attempted or were impossible because of technical difficulties. It should be noted that the technique is rigorous and requires great care in its manipulation, and technical artefacts therefore frequently creep into the study. In every case where correlations were possible, the primary axis of the organism came to lie along the plane which showed the greatest voltage drop from the vertex. In other words, it was possible to predict from the voltage pattern where the head end of the organism would develop. It is hard to escape the conclusion, therefore, that the electrical pattern is primary, and, in some measure at least, determines the morphological pattern. Added weight is given to the argument by other observed facts.

Effects of β-Naphthoxyacetic Acid on Plants

P. W. ZIMMERMAN described some studies of this subject on April 28 at the annual meeting of the U.S. National Academy of Sciences. Many growth substances have in common the capacity of inducing similar responses in plants; that is, they cause cell elongation, increase cell division, and induce adventitious roots. There are, however, many qualitative differences in the capacity of chemically similar compounds to induce physiological responses. For example, β-naphthoxyacetic acid and its derivatives modify the new organs (leaves, stems, flowers and fruit) which are formed after the growing points are treated with the substance. The pattern and venation of compound leaves become modified, appearing frenched and fasciated. Leaflets frequently grow together on portions of compound leaves. Compound types sometimes become simple leaves and again doubly compound. Both the pattern and opaqueness of veins are modified. Veins of modified leaves show clearing which is usually characteristic of virus-diseased plants. Tobacco plants sprayed at the tip with a solution (300 mgm./l.) of β-naphthoxyacetic acid grow taller and flower ahead of controls. Treated delphinium plants also flower ahead of controls. Unless plants are re-treated at intervals they recover and again produce normal leaves and flowers. Parthenocarpic development of tomato fruit is induced when flowers or well-developed buds are sprayed with emulsions or solutions of naphthoxyacetic acid. The ovaries often enlarge before the flowers open, eventually breaking through on one side of the calyx tube. The floral parts—petals, stamens and pistils—persist for an abnormally long time during parthenocarpic development. In some cases both petals and stamens remain in good condition for 30 days whereas controls wither within 3 days after the flowers open. Compared with other growth substances, naphthoxyacetic acid has several advantages for practical production of seedless tomatoes and possibly of other fruits.

Biotin and the Growth of *Fusarium avenaceum*.

THE effect of biotin on the growth of *Fusarium avenaceum* was described in a paper by W. J. Robbins read on April 28 at the annual meeting of the U.S. National Academy of Sciences. A strain of *Fusarium avenaceum* obtained from South America does not grow in a solution of mineral salts and sugar but grows in the same solution solidified with agar. The beneficial effect of agar on the growth of this organism is chiefly because of biotin (vitamin H) present in the agar. Purification of the agar by extraction with aqueous pyridine removes the biotin and makes the agar ineffective in permitting growth of the fungus. The amount of biotin present varies with the sample of agar, but approximates to 0·1 microgram per gram in some samples. This is as much or more than is present in dried egg yolk. Agar was more beneficial than could be accounted for by its biotin content. A beneficial effect of 0·001 microgram of pure biotin (obtained from Dr. Vincent du Vigneaud) on the growth of the Fusarium in liquid culture was observed and amounts of biotin up to 0·1 microgram per culture further increased the dry weight. Some isolations made from old cultures of the fungus grew in the absence of biotin; these were interpreted to be saltations or dissociations.

Nitrogen/Phosphorus Relations in Lemon Seedlings

IN a paper read before the Royal Society of South Africa on March 19, J. W. Pont discussed the nitrogen–phosphorus relations in Rough lemon seedlings. No negative correlation between nitrogen and phosphorus could be observed in either the leaves, the stems or the roots. A positive correlation between nitrogen and phosphorus existed in the roots only. Roots, stems and leaves form distinct metabolic systems, and it appears plausible to accept that fruits form a separate system.

Drainage of the Fens

THE problem of the disposal of the Ouse floods and the Fen drainage has been much to the fore since the heavy floods of a few years ago. The various schemes that have been suggested are described and discussed by W. E. Doran in a paper on the Ouse flood problem in the *Geographical Journal* of April. Perhaps the most striking of the various proposals is that by Sir Murdoch MacDonald and Partners. This entails intercepting the upland waters in the headstreams of the Ouse and preventing them passing through the Fen area. It would involve the construction of a circular canal to the east of the Fens from the Cam at Grantchester via the Lark, the Little Ouse and the Wissey, at Stoke Ferry, to Denver, whence a new canal, suggested also by other authorities, would carry the water roughly parallel with the Ouse but more direct, to the main river at St. Germans. It is only as high up the Cam as Grantchester that a suitable level for the flow of water down this channel could be reached. Hence the impossibility of beginning it below Cambridge. Further details of the scheme, and the location of sluices and pumping stations, are explained in the paper and its accompanying map.

Divisions of the Pleistocene

THE correlation of Pleistocene deposits throughout the world presents many difficulties. In a paper on this subject (*Trans. Roy. Soc. Edin.*, 60, Part II, No. 11) T. T. Paterson points to the imperfection of the fossil record, the shortness of the whole period and consequent difficulty of subdivisions based on faunal development, and largely, the stress that has been laid on different phenomena in studies of the period in different lands. He surveys the available evidence from a wide area, examining especially the fluviatile deposits, and he amplifies the scanty fossil record by the use of palæolithic horizons. To these he pays particular attention and gives a survey of culture development during the period. Paterson concludes that variations in power-volume, the result of combined orogenic and precipitational changes, are coincident throughout the Old World. The variations result in three great cycles of sedimentation divisible into seven phases. The first, second and third glacial episodes coincide with the beginning of each cycle, and the fourth with the third phase of the last cycle. The fifth glacial episode marks the end of the Pleistocene. It is proposed to divide the Pleistocene into Lower, Middle and Upper, with seven phases termed L_1 L_2 M_1 M_2 U_1 U_2 U_3, to show their relationship with the three major subdivisions (see also NATURE, 146, 12–15 and 49–52; 1940). In a discussion on the causes of power-volume changes, Paterson concludes that G. C. Simpson's theory of variation in solar radiation explains most of the phenomena.

Electrophoretic Study of Complexes between Proteins, etc.

D. A. MACINNES and L. G. Longworth described some experimental work in the above connexion before the annual meeting of the U.S. National Academy of Sciences, on April 29. In their study of egg white, by a modification of the method of Tiselius, evidence was obtained that complexes exist between the proteins in the naturally occurring material and also in salt and buffer solutions. The evidence comes largely from the fact that in certain cases the electrophoretic patterns for the rising and descending boundaries are not, even approximately, mirror images of each other, as would be expected if the components were electrophoretically independent. The effect is greatest for relatively high protein concentrations and low salt contents of the solutions used in the studies. Complexes are most often found between proteins on opposite sides of their isoelectric points, but this is by no means a necessary condition for their occurrence. As type systems, electrophoretic studies have been carried out systematically on mixtures of ovalbumin and yeast nucleic acid, and on this nucleic acid with ovomucoid, varying the relative concentrations, the *p*H values and the ionic strengths. The electrophoretic pattern for a mixture of ovomucoid and nucleic acid is particularly interesting in that it indicates a peak for an extra component. The apparent relative concentrations, as indicated by the areas under the different peaks of the patterns, are altered by complex formation. With the mixture of ovalbumin and nucleic acid the components were found to form complexes if the *p*H were near or below the isoelectric point of ovalbumin, but to be electrophoretically quite independent at high *p*H values.

Temperature and Variations of Cosmic-Ray Intensity

THE correlation between the seasonal variations of cosmic-ray intensity and temperature of the atmosphere are examined by A. Duperier (*Proc. Roy. Soc.*, A, 177, 204; 1941) using data for Europe and the United States. A lag in the warming of the atmosphere in spring is found to be paralleled by a lag in the diminution of intensity of the cosmic rays. The correlation is closer with the mean temperature of the atmosphere up to 16 km. than with temperature near the ground. The temperature coefficient of the cosmic rays as deduced from the seasonal data is 0·18 per cent per degree C., in rough agreement with theory.

ÆSTHETIC APPEAL OF OSTWALD'S CHROMATIC STANDARDS

By Dr. J. B. Parry
University College, London

In Nature of May 31, p. 682, Dr. H. J. Eysenck has examined a number of claims made by Ostwald for his colour system. It may be of interest to put on record two experiments I have recently carried out relating to the æsthetic appeal of Ostwald's chromatic circles; the first deals with the appeal of single hues, the second with that of triple combinations. The detailed account of the experiments will be found in my Ph.D. thesis (London, 1940) entitled "The Rôle of Attention in Æsthetic Experience".

Preferences for Single Hues

It is desirable to explain that, according to Ostwald, the physical composition of any colour stimulus may be shown by an equation of the form: Hue+Black+White = 1. Circles, known as isovalents, can be defined, for any one of which the same equation holds for all its members, only the hue quality varying from one member to another. A condensed formula for each circle is given by two letters, the first indicating the proportion of white content, the second that of black content. There are of course many tint circles ranging from near white to near saturation and many shade circles from near black to near saturation; those selected here are intermediate.

The materials for the first experiment were twenty-four Ostwald papers cut to the size of 3½ in. square and backed with stiff cardboard. The selection comprised three sets of eight items each, the first containing fully saturated hues (circle *na*), the second tints (circle *ga*) and the third shades (circle *ng*). In each set the middle values of the eight principal hues were chosen. Fifteen educated persons were asked to grade these items according to preference by linear ranking, the test being performed in daylight against a background of white blotting-paper.

Factorial analysis of the resultant intercorrelations of persons by simple summation revealed a first factor responsible for 26·5 per cent of the variance. From this it seems clear that there is a strong tendency to general agreement as to the pleasantness or unpleasantness of single hues.

The relative popularity of the individual items may be estimated by summing the positions allotted to each by the fifteen subjects. From the resultant order of popularity of twenty-four items one can of course abstract an order of popularity for the eight hues in each of the three circles. These latter orders are shown in the following table, the figures in brackets showing the positions of the items in the order of popularity of all twenty-four items.

Order of Popularity of the Items in the Three Circles

Circle Hue	*na*	(Full Saturation)	*ga*	(Tints)	*ng*	(Shades)
Yellow	7	(20)	8	(18)	8	(24)
Orange	6	(15)	7	(22)	6	(17)
Red	1	(1)	4	(9)	4	(13)
Purple	5	(14)	6	(21)	5	(16)
Ultramarine	2	(2)	3	(8)	1	(7)
Turquoise	4	(6)	1	(3)	7	(19)
Sea Green	3	(4)	2	(4)	2	(11)
Leaf Green	8	(23)	5	(10)	3	(11)

The high positions of all three ultramarines and sea greens and the marked unpopularity of the oranges and yellows will be noted.

Preference for Triple Combinations

Ostwald makes two specific claims regarding the appeal of triple combinations: first, that membership of the same circle is a condition favouring harmony; secondly, that among terms fulfilling this condition, equality in the psychological intervals between the terms is a further favouring condition (this second claim rests on the assumption that the intervals between successive terms on any Ostwald circle are all psychologically equal); this point was one of many investigated by Prof. C. Burt a number of years ago—he reached the conclusion that the intervals were often far from equal, an opinion also expressed by Eysenck in his recent article in this journal.

In framing the following test Ostwald's claims were borne in mind. The materials for this second test consisted of 24 triple combinations, comprising four groups:

(1) Eight equally spaced combinations from the standard hue circle *na* (for example, 1, 9, 17; 7, 15, 23, etc.). In this group both the above conditions are realized.

(2) Eight unequally spaced combinations from the standard hue circle, each of the four possible degrees of inequality being represented twice (for example, 1, 16, 17; 2, 15, 18; 3, 14, 19; 4, 13, 20). In this group the first of the above conditions is realized, the second is violated.

(3) Four equally spaced combinations, the three terms of each combination being drawn from three different circles, namely, the standard hue circle *na*, a tint circle *ia*, and a shade circle *ne*. Here the first condition is violated and the second observed.

(4) Four combinations (two equally spaced, two unequally spaced) from a grey shade circle *ie*.

Fourteen persons, all but one adult, were asked to award marks to groups of these on the principle: 8 marks to the one liked best, 7 to the next best, 6 to each of the next three . . . 0 to the one liked least. The test was carried out in daylight against a background of ordinary newsprint. Factorial analysis showed a first factor covering 31·66 per cent of the variance and a significant second factor accounting for a further 22·81 per cent.

The most impressive fact revealed by inspection of the preferences is that the seven subjects whose rankings approximate most closely to the average order have accorded maximum marks to the four greyed combinations; of the remaining seven, five have placed the members of this group slightly lower than midway, one has marked them very high and one very low. But this preference does not entirely account for the first factor discovered.

The four combinations with very unequal intervals were found extremely unpleasing by all but one of the subjects. This appears at first to support Ostwald's contention that the basis of harmony is equality of spacing; when, however, we compare the marks allotted to the equally spaced combinations with those that show a moderate inequality we find no further confirmation of the claim. As for the claim that membership of the same circle is a condition favouring harmony, the evidence at our disposal points, if anything, the other way.

Since no amount of inspection enabled me to discern the nature of the second factor, I decided to carry out a second test removing the four greyed combinations and the three least popular of the unequally spaced combinations. I then asked a dozen people (ten of whom had done the previous test) to range the remaining seventeen combinations by linear method. The results brought to light a truly dominating bipolar factor. Inspection of the items most diversely judged reveals two characters that it is easier to perceive than name. Some idea of the characters may possibly be indicated by pointing out that the leading members of one set each contained a pale green and a pale red, while those of the other set contained orange-yellows and deep greens. What is of special psychological interest is that no trace of this factor can be seen in the results of the original test, in which, of course, all the seventeen items were included. It appears that before these characters could be attended to, other more striking qualities such as greyedness and wide inequality of interval had to be eliminated. Once this has been done, these characters carry all before them.

In these tests of triple combinations, the three terms in each item were made to cover equal areas. This, of course, made it improbable that anything like the most pleasing combinations were reached. To achieve this result many more experiments would be necessary, and I hope in due time to carry these out. But the relative unpleasantness of the items in the tests so far done has not made it impossible to discern some of the principles influencing subjects in their assessment of the relative merits of colour combinations. What stands out with especial clearness is the complexity of the problem of colour harmony; any attempt, like Ostwald's, to explain it by a single principle seems foredoomed to failure.

THE BONE-BEARING BEDS OF BETHLEHEM

THE excavation of the bone-bearing beds of Bethlehem was undertaken by the Wellcome Archæological Expedition to the Near East under the auspices of the Department of Antiquities, Palestine, and work was carried on for three seasons (1935–7) with E. W. Gardner as geologist and D. M. A. Bate as palæontologist. The continuation of the work in 1937 was made possible through the support of the trustees of the late Sir Henry Wellcome, and of the late Sir Robert Mond. A preliminary account of the results was published in NATURE of September 4, 1937.

No work was done on the site in 1938 or 1939, but last year (1940) the co-operation of Dr. Stekelis of the Hebrew University was enlisted to complete the excavation so far as possible. His report has now been received and shows that some notable results have been achieved. In the area from which specimens had already been obtained, work was continued to a depth of several metres below the last occurrence of animal remains, but it was not possible to test the horizontal extent of the bone bed. The geological and archæological finds do not seem to provide very definite or final evidence regarding the history, or the possible human occupation of the site, but an interesting suggestion is made by Dr. Stekelis that a number of split bones collected may have been worked by man. A detailed study and comparison of these specimens should prove of exceptional interest.

A considerable quantity of animal remains was obtained, and the specimens will be sent in due course to the British Museum (Natural History) for study and description, together with those of the earlier collections. Dr. Stekelis's list shows that at least six species are recognized; they are as follows:

Bos sp.
Antelope
Equus sp. (? Hipparion)
Rhinoceros sp.
Elephas sp.
Testudo sp.

A number of valuable specimens were recovered and these include a mandibular ramus with teeth, and an almost complete skull with cheek teeth of Rhinoceros; Elephas or Stegodon is represented by a ramus with molars, as well as by isolated teeth and limb bones. Portions of jaws with teeth of antelope, and various remains of ox are also present. All these should be of value not only for determining the species, but also in interpreting the geological age and the relationship and status of this very interesting fossil fauna.

D. M. A. B.

VELOCITIES OF EARTHQUAKE WAVES

FRANCIS BIRCH has published a paper entitled "The Variation of Seismic Velocities within a Simplified Earth Model, in accordance with the Theory of Finite Strain" (Paper 55, Geophysical Research, Harvard University), which marks a somewhat new direction for seismological research.

The author states that the treatment of many problems concerning the elasticity of the earth as a whole has been handicapped by the lack of an adequate theory of finite deformation, which would permit quantitative estimation of the effects of the initial strain of the material below the surface. While certain artifices which have been employed to evade this difficulty have had the merit of adding a sufficient number of conditions to allow the solution of various special problems, they have proved incapable of answering such fundamental questions as "Given a layer or a spherical shell of perfectly elastic (not incompressible) material, isotropic, homogeneous, and at uniform temperature, to find the variation of density and of the velocities of elastic waves due to self-compression in a gravitational field". Answers to these questions may naturally be sought in the results of high-pressure experiments, but at best the pressures realizable in the laboratory correspond to small depths in relation to the earth's radius.

A theory which will allow quantitative prediction of the effect of pressure upon density and elasticities can evidently be of great assistance in dealing with the vast region which will probably always remain beyond the range of experimental technique. In the opinion of Mr. Birch, a theory of this character has recently been provided by F. D. Murnaghan ("Finite Deformations of an Elastic Solid", *Amer. J. Math.*, **59**, 235–260; 1937), and Birch applies the theory to a study of the density and velocity variations in a simplified model of the earth outside the core, consisting of two homogeneous layers at uniform temperature. The layers are separated by a first order discontinuity at a depth of 474 km. (after Jeffreys). The velocities obtained are in fair agreement with those obtained by Jeffreys and Bullen, and the variations of density are very similar to those derived by Jeffreys and Bullen by numerical integration of the 'observed' velocities, on the supposition of adiabatic compression of homogeneous layers. The validity of their method is shown to depend upon the existence of a small temperature gradient, or of compensating factors which cannot be evaluated. It is suggested that a more rigorous solution of the equations of motion derived from the theory of finite strain might prove of value in interpreting the oscillatory character of seismic records, as well as the direction of the ground motion associated with various wave types.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

DEPUTY DIRECTOR OF EDUCATION—The Director of Education, Education Office, St. Helens (endorsed 'Deputy Director of Education') (June 27).

DEMONSTRATOR in the Department of Zoology—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (June 28).

ASSISTANT to the Engineer-in-Chief—The General Manager and Secretary, Mersey Docks and Harbour Board, Dock Office Liverpool (June 30).

PROFESSOR OF PHYSIOLOGY at the London (Royal Free Hospital) School of Medicine for Women—The Academic Registrar, University of London, Royal Holloway College, Englefield Green, Surrey (July 1).

AGRICULTURAL MARKETING ADVISER to the Government of India—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (July 2).

ASSISTANT DIRECTOR OF EDUCATION—The Director of Education, Education Office, Becket Street, Derby.

FORTHCOMING EVENTS

Monday, June 23

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 3 p.m.—Annual General Meeting. (Presidential Address.)

Tuesday, June 24

ROYAL ANTHROPOLOGICAL INSTITUTE of Great Britain and Ireland (at 21 Bedford Square, London, W.C.1), at 2.30 p.m.—Annual General Meeting. Prof. A. R. Radcliffe-Brown: "The Study of Kinship" (Presidential Address).

REPORTS AND OTHER PUBLICATIONS

(*not included in the monthly Books Supplement*)

Great Britain and Ireland

Empire Cotton Growing Corporation. Progress Reports from Experiment Stations, Season 1939–1940; Programmes of Experiments, Season 1940–1941. Pp. vi+176. (London: Empire Cotton Growing Corporation.) [235

River Flow Records of the River Moriston at Invermoriston for the Water-Years ending respectively on September 30th of 1938, 1939 and 1940. By Capt. W. N. McClean. Pp. 10. (London: River Flow Records.) [265

The Zoological Record. Vol. 76: Being Records of Zoological Literature relating chiefly to the Year 1939. Compiled for the Zoological Society of London by A. G. Brighton, M. Burton, A. B. Hastings, C. A. Hoare, W. Nicoll, A. E. Salisbury, J. K. S. St. Joseph, W. L. Sclater, M. A. Smith, C. J. Stubblefield, E. Trewavas, E. I. White, R. J. Whittick, and the Imperial Institute of Entomology. Edited by Malcolm A. Smith. Pp. 1420. (London: Zoological Society of London.) £3; also issued in 19 separate Sections. [285

Other Countries

Government of India Industrial Research Bureau. Report for the Year 1939–40. Pp. iv+40+2 plates. 1.2 rupees; 1*s*. 9*d*. Bulletin No. 19: Indian Vegetable Oils as Fuels for Diesel Engines. By H. D. Chowdhury, S. N. Mukerjee, J. S. Aggarwal and Dr. Lal C. Verman. Pp. iv+28+7 plates. 1.6 rupees; 2*s*. (Delhi: Manager of Publications.) [205

Occasional Papers of the Bernice P. Bishop Museum. Vol. 15, No. 28: *Ophioglossum*, *Rollandia* and *Scaevola*. By Harold St. John. (Hawaiian Plant Studies, 9.) Pp. 351–360. Vol. 15, No. 29: Plant-parasitic and Free-living Nematodes in Hawaii. By J. M. Oliveira. Pp. 361–374. Vol. 16, No. 1: New Species of Dicotyledonous Spermatophytes from Tahiti. By John W. Moore. Pp. 24. Vol. 16, No. 2: A Revision of the Hawaiian Species of Myrsine (*Suttonia*, *Rapanea*), (*Myrsinaceae*). By Edward Y. Hosaka. Pp. 25–76. Vol. 16, No. 3: Three Polynesian Ferns. By E. B. Copeland. Pp. 77–80. Vol. 16, No. 4: Itinerary of Hugh Cuming in Polynesia. By Harold St. John. Pp. 81–90. Vol. 16, No. 5: New Species and New Records of Elaterid Beetles from the Pacific. By R. H. Van Zwaluwenburg. Pp. 91–130. Vol. 16, No. 6: Coleoptera from the Caroline Islands. By K. G. Blair. Pp. 131–158. Vol. 16, No. 7: Report on a Collection of Samoan Coleoptera. By Elwood C. Zimmerman. Pp. 159–176. Vol. 16, No. 8: A Revision of the Genus *Deretiosus* (Coleoptera, Curculionidae). By Elwood C. Zimmerman. Pp. 177–214. (Honolulu: Bernice P. Bishop Museum.) [215

Commonwealth of Australia: Council for Scientific and Industrial Research. Pamphlet No. 104: The Australian Tunas. By Dr. D. L. Serventy. (Division of Fisheries: Report No. 4.) Pp. 48+4 plates. Pamphlet No. 105: The Biology and Cultivation of Oysters in Australia. 1: Some Economic Aspects. By G. L. Kesteven. (Division of Fisheries: Report No. 5.) Pp. 32. (Melbourne: Government Printer.) [235

Transactions of the Academy of Science of St. Louis. Vol. 30, No. 4: The Agricultural Economy of the American Bottoms in Madison and St. Clair Counties, Illinois. By Prof. Mendel E. Branom. Pp. iv+90+143. (St. Louis, Mo.: Academy of Science of St. Louis.) [235

Astronomical Papers prepared for the Use of the American Ephemeris and Nautical Almanac. Vol. 10, Part 2: Catalog of 3539 Zodiacal Stars for the Equinox 1950.0. Pp. 167–300. (Washington, D.C.: Government Printing Office.) 30 cents. [265

Field Museum of Natural History. Geological Series. Vol. 8, No. 4: A New Fossil Alligator from Nebraska. By Karl P. Schmidt. (Publication 494.) Pp. 27–32. 10 cents. Zoological Series, Vol. 24, No. 20: Two New Birds from British Guiana. By Emmet R. Blake. (Publication 495.) Pp. 227–232. 10 cents. (Chicago: Field Museum of Natural History.) [265

Studies on the Microflora of the Dead Sea. By Benjamin Elazari-Volcani. Pp. xiii+121+17 plates. (Rehovoth: The Author, Daniel Sieff Research Institute.) [265

Canada: Department of Mines and Resources: Mines and Geology Branch, Bureau of Mines. Investigations in Ore Dressing and Metallurgy (Testing and Research Laboratories), July to December 1939. (No. 806.) Pp. iii+116+2 plates. (Ottawa: King's Printer.) 25 cents. [275

LE COQ D'OR

KING DODON was mighty anxious. His kingdom was threatened, yet though in his youth and prime he was a redoubtable monarch, he had long since ceased to care for warlike pursuits. Following the example of their monarch, the people too were contemptuous of the profession of arms, and their young men gave themselves up to pleasure.

The rulers of neighbouring domains were not slow in taking advantage of this state of affairs, so now here was King Dodon threatened with the dangers of invasion. In council, Prince Guidon advised his father. "The chief of our troubles," he said, "is that our enemy is so near to us that he is already about to fall upon our army and annihilate it. Let us, then, bring back our warriors from the borders and place them around our beloved capital to protect it and ourselves from harm."

All the company were delighted, except Prince Afron and the venerable head of the army, Polkan. They angrily opposed such a foolish plan. So King Dodon asked the advice of his son Afron who said: "Recall our soldiers just a month before the enemy attacks, and then we will go forth and crush him."

With all this conflicting advice, no wonder King Dodon was puzzled, and it is not surprising that disorder broke out in the company of the Council.

Then in the midst of this confusion there appeared at the top of the stairway a very old and venerable-looking Astrologer. He carried in one hand an astrolabe and in the other a bag. "Hail, King Dodon! Although thou knowest not me, yet art thou well known to me. . . . I have come to offer unto thee a magic remedy, so that thou mayest once more sleep in peace. . . . Accept my Golden Cockerel, O Sire, and place it upon the highest spire upon thy palace; and it shall be a true watchman unto thee. When all is peaceful and quiet, it will make no sound whatever . . .; but if enemies are about, or if thy peace is threatened in any way, then will my magic Golden Cockerel raise his comb, flap his wings, and turning in the direction from whence the danger appears, will crow aloud 'Cock-a-doodle-do! Beware!' "

That is how the story of Rimsky-Korsakov's pantomime-opera "Le Coq d'Or" opens. It does not tell us how old that Golden Cockerel was, nor for how many years the Astrologer had possessed it; but six years ago another 'Golden Cockerel' began to develop, and now, having proved its ability to call "Cock-a-doodle-do! Beware!" at the appropriate moment, it, together with its 'Astrologer', was introduced to the world by a Minister of State on June 18, 1941.

But there is nothing very new in this announcement and appeal, both at home and overseas, for radio engineers, physicists, etc., to play their part in helping the Cockerel to crow. That is, it is not very new to men of science. Radiolocation, in its origin, was the conception of one man, Mr. R. A. Watson Watt, C.B., F.R.S., scientific adviser on telecommunications to the Chief of the Air Staff, who, with his collaborators and assistants, aided it in its development from chick to adult. No; neither the Cockerel nor its Astrologer are very new to science, for Watson Watt's researches in radio engineering, especially while at the National Physical Laboratory and at the Bawdsey Research Station, have earned for him a world-wide reputation among men of science, and he is the author of many contributions which have appeared in our columns

The Astrologer said: "Although thou knowest not me, yet art thou well known to me." How true has that been in modern times. How pitifully few of the people, and especially of their leaders, have even bothered to examine what Science has to offer them; and how few are there who know, or express appreciation of, the work of Science behind all the advances—technical, biological, medical, etc.—of this age. It is necessary for national emergencies and modern 'Astrologers' to bring it all home to them. Lord Beaverbrook, on the occasion of the announcement of Watson Watt's great achievement, has now impressed it upon the people that "Technical developments make progress in war which sometimes outstrips all that has gone before. . . . It is the scientist who will heal our wounds. It is the scientist who will protect us against the loss of our life-blood. It is the scientist who will save our home and guard our hearthstones."

Thus on the basis of the work of Watson Watt, Sir Frank Smith and others, did the Minister of State make his call to service: "Man the front line of Science." No doubt men and women from all parts of the world will respond to the call, and thus will Science have made in an almost glamorous way another of her many contributions towards victory in war, for truly this is not only a war of machines—for that is only a part of the story; it is a war of Science, the science of defence, the science of living against great odds, and, alas, the science of destruction.

But what is to be the result of all this? What did the Astrologer demand in the end? He declared that the ordinary gifts of riches and high rank were as nothing to him, since he regarded love only as precious, and at the end of the story he demands the hand of the Queen of Shemakhan. So this is where modern Science and the ancient Astrologer must part company.

Through such men as Watson Watt, the people are learning the first-rate value of Science in modern warfare; so now let Science build up evidence for her claim for all-out recognition and for her just status in times of peace.

How often has this been emphasized in NATURE. But society has still to realize it fully. Even in medicine most people recognize only the medicine of disease. Either they do not recognize or they ignore the medicine of health. They recognize the work of a medical man only when, through illness, they need him. Little do they know of preventive medicine. So is it with Science. Science can be constructive as well as destructive. Which it is to be depends upon society. She offers us a good, strong, useful rope; is it her fault if we choose to hang ourselves with it? Science has played and will have to play, a very important part in the advancement of civilization and the improvement of social life. Little have men of affairs realized or recognized this in the past.

In his appeal, Lord Beaverbrook referred to "the hour when men of science can turn again to the thoughts and the labours of peace". The exigencies of war have constrained many men of affairs to recognize and to appreciate what Science has to offer. The War Minister, too, announced to the House of Commons on June 18 that there might be occasion for the appointment of a special scientific attaché to foreign Governments in view of what Lord Beaverbrook had said in his broadcast appeal. But Science offers more, much more, than weapons of destruction and materials for defence. She offers a horn of plenty, full of good, constructive ideas and machines. When the hour of peace comes, is she to be discarded as something only useful in confounding our enemies? Are Mr. Eden's attachés to be recalled? If so, then our men of affairs will prove to have been opportunists who have learned nothing.

Our Army, Air Force and Navy are in the front line of action. But there are many other fronts—our kitchens, gardens, farms and factories—and not least of all, Science. We have learned of the folly of neglecting our fighting forces in those times of peace when certain sections of the world were treating a period of peace as one of preparation for war. Until the world is ready for a real and lasting peace, we must bear that lesson in mind, once victory is achieved. This applies also to Science. Let her be recognized and encouraged in the everyday lives of the many; let her too be admitted to the council of the chosen few. Never let her be neglected or merely taken for granted again.

Men of science are becoming very conscious of their duty to society. Will society, in the peace to follow, recognize its obligations to Science and avail itself of all the good things that this war is proving Science has to offer? Men of science will be able to offer new and possibly strange tools to society; will society take them and tackle the job of building and maintaining the peace—a job infinitely more difficult than that of winning the war?

"The scientist will heal our wounds."

SOVIET RUSSIA

ON Sunday, June 22, the Nazi war machine was set in motion against Soviet Russia, without even the prelude of an ultimatum.

One by one the nations of Europe have been made subject to direct or indirect Nazi domination, and, with the failure of early attempts to break the resistance of the British Empire and the Free men of the occupied countries now fighting with us, and in apprehension of the effect of the growing weight of support from the United States, the Nazis have turned to the east in an attempt to seize the natural resources of Soviet Russia and to immobilize her armies. Beyond the immediate aims there is little doubt that the intention is to foment strife beyond Europe, in Iran, India and China, and elsewhere in Asia. It is all part of the gigantic scheme to dominate the world by terror and force, to subdue the peoples of all countries and to make them the slaves, body and soul, of Germany.

Mr. Winston Churchill drew a moving picture of the situation as he described it in a broadcast to the world on the evening following the invasion. "It is not too much to say, here this summer evening, that the lives and happiness of a thousand million additional human beings are now menaced with brutal Nazi violence. . . . The Nazi regime is indistinguishable from the worst features of Communism. It is devoid of all theme and principle except appetite and racial domination. It excels all forms of human wickedness in the efficiency of its cruelty and ferocious aggression." A vital decision had to be taken at once by His Majesty's Government, and there will be agreement everywhere with Mr. Churchill's announcement: "We have offered to the Government of Soviet Russia any technical or economic assistance which is in our power and which is likely to be of service to them." It matters not what political label be given for the time being to any nation or group of peoples; we cannot withhold our support from anyone who attempts to withstand the Nazi menace.

Soviet Russia has passed through many vicissitudes since it began to emerge from the Revolution of 1917. Internal difficulties have been numerous. There have been hardship and cruelty. But slowly, and with many hesitating moves, a system of government was built up which bound together the vast Russian territories in Europe and Asia into an organic whole. Some of us may not have sympathized with the ideological background which was developed; others have hailed the evolution of Soviet Russia as a symbol of the form of organized society towards which the nations should move. As Mr. Churchill said, all this must now be put aside. We are faced with an elemental fact. The Russian people now attacked are men and women. They have grown up with a measure of self-government. They have developed the industries of their country; education has been promoted; science and scientific research have received support. Institutes devoted to research have begun to function, as many communications published in NATURE from time to time until a few months ago have shown. Freedom of research as the English-speaking nations know it has not yet been achieved; nevertheless valuable work has been done. We need only recall in this connexion the names of the physicists Kapitza and Joffe, and of the geneticist Vavilov, all of whom have international reputations. These people are being attacked by the sworn enemy of democracy and all that it stands for: "Any man or State who fights Nazism will have our aid."

The attack on Soviet Russia represents, as Mr. Churchill put it, the fourth climacteric in this War; it was marked by "the same kind of outrage against every form of signed compact and international faith which we had witnessed in Norway, Denmark, Holland and Belgium". Freedom of thought leads to freedom of speech, one of the cardinal principles of democracy. This in turn requires the recognition by the individual of the rights and liberties of others; individual liberty must submit to restraints imposed by the needs of society. Such restraints may or may not be codified and become laws, but their observance is a condition upon which the continuance of human society depends. Similarly, in the field of international relationships, the rights of the several nations to their own modes of government must be respected, and the terms of solemnly pledged treaties must be honoured. It will be the task of men of all races, creeds and parties, so to work together after the War that law-breaking among the nations becomes impossible. Lawlessness in international affairs is inimical to the progress of civilization.

HOT SPRINGS AND GEYSERS OF ICELAND

On Thermal Activity in Iceland and Geyser Action

By Thorkell Thorkelsson. Pp. 139. (Reykjavík: Ísafoldarprentsmidja H.F., 1940.)

NOWHERE is thermal spring activity so intense and widespread as in Iceland; many thousands of hot springs are known and in addition many more exist beneath the glaciers and on the shallow sea floor. The lives of the springs vary from a day to hundreds of years. The large spring Reykjalaug is known to have existed in A.D. 1000 for it is reported in the "Kristni saga" that when at that time Christianity was adopted by Parliament the remaining heathen northerners rode to Reykjalaug to be baptized as they refused to suffer this in cold water. In recent years extensive works have been carried out to utilize the springs in heating houses, schools, hospitals and greenhouses and in the provision of public baths. There is a virtually inexhaustible store of energy in the hot ground waters and the future should see further extension of its service to man.

Many famous names are associated with the early study of thermal activity in Iceland; the work of Bunsen is perhaps the best known. No one has paid more attention to the subject than Thorkell Thorkelsson, and this memoir, which includes reflections based upon a life's study, is of prime importance; it is only unfortunate that the absence of sub-headings and somewhat rambling treatment of this long essay will deter some from reading it.

The springs occupy the site of historic volcanic activity and its neighbourhood, and there can be no doubt that the heat is of magmatic origin. With the pouring out of lava at the surface it is reasonable to suppose that a volume of magma remains to cool in the outer part of the earth's crust, and the ground waters are heated by contact with hot rock and by absorption of super-heated steam and other gases given off from the crystallizing magma. It is impossible to determine how much (if any) of the spring water is magmatic, but there is abundant evidence that the water is largely of surface origin—a geyser near the coast at Reykjanes delivers almost pure sea water. Outside the volcanic regions of recent date the gases other than water vapour emanating from the springs consist almost entirely (usually 98 per cent by volume) of nitrogen and argon, in similar proportions to those of the atmosphere, and it may be assumed that in these cases dissolved air has lost its oxygen by combination with the rocks. Within the volcanic region the prominent gases are hydrogen, carbon dioxide and sulphuretted hydrogen, and these are probably of magmatic origin.

Normally the heat is conveyed to the surface and dissipated continuously: only a very small proportion of the springs are geysers. In all likelihood the supply of heat at source is constant and the fundamental cause of geyser action is to be found in the circumstance that the heat acquired in depth cannot be carried away at the rate at which it is added, but accumulates until such instability results that the hot water is violently ejected. The time required for the heating up of the cooler water, then coming in to fill the channels and chambers of the geyser system, readily accounts for the intermittency of the eruptions: the main difficulty is to establish what causes the start of an eruption. Early theories are based on the conception of super-heating: the temperature is supposed to rise at some point until steam is formed with progressive fall of hydrostatic pressure and with consequent expulsion of the water. Observations, however, have not revealed the attainment of super-heat in depth, neither has a continuing increase of temperature been found in the quiescent intervals; if super-heat is attained it must be in greater and inaccessible depths.

Thorkelsson advances reasons for doubting any common development of super-heat; he sees in the spring gases the cause of most geyser eruptions, and cites examples of eruptions where the temperature was below 100° C. "even deep down in the subterranean channels". Gas bubbles are visible in most Icelandic springs and at high temperatures are largely composed of water vapour. "However, the spring gases in spite of their fractional smallness constitute a necessary condition for the existence of the bubbles. If the spring gases were removed the bubbles would collapse immediately."

The essence of Thorkelsson's theory is that swarms of gas bubbles form as the water rises, and the hydrostatic pressure of the gas and water mixture being less than that of water alone (the air-lift pump principle), a reduction of pressure results which may produce an uprush of water sufficient to start the eruption. With this the water will, in many cases, come to boil at the lower pressures experienced in its rise and steam will then play its part; but the fundamental cause of the uprush is considered to lie in the separation of the gas bubbles. It is significant that geysers have been converted into normal springs by putting stones in the channels to retard the flow, also that springs have been converted into geysers by the removal of channel obstructions.

No two geyser systems are the same; they differ in the number, size, form and attitude of the subterranean spaces. As the upper pipe open to investigation is only a small part of the system and, moreover, is not as a rule the site of the development of the expulsive force, it is not surprising that no general theory can be formulated to cover all cases; the statement by Day and Allen in their work on "The Hot Springs of the Yellowstone National Park" (1935) that in their experience the permanent gases are extremely scarce in geysers generally must not be forgotten. L. Hawkes.

BIOLOGICAL FIXATION OF NITROGEN

The Biochemistry of Symbiotic Nitrogen Fixation

By Prof. Perry W. Wilson. Pp. xiv+302+34 plates. (Madison, Wis.: University of Wisconsin Press, 1940.) 3.50 dollars.

The study of the nitrogen fixation which proceeds within nodule-bearing leguminous plants provides a common meeting-ground for several branches of natural science. Bacteriologists, botanists, chemists, students of agriculture, all have found opportunities, not always lucrative, for investigation. The attention lavished on the subject by such varied workers, while it ought to result in a more all-round progress, inevitably complicates the task of anyone attempting to keep in direct touch with the multitude of original publications, dispersed as these are through scientific journals of every description. There should, therefore, be a ready welcome for a monograph such as that prepared by Prof. P. W. Wilson with the help of his colleagues in the Department of Agricultural Bacteriology of the University of Wisconsin, especially since it bears the hallmark of authority of a distinguished centre for the study of biological fixation of nitrogen.

The monograph is described as a sequel to the well-known earlier one from the same department by Fred, Baldwin and McCoy, and refers especially to those aspects of symbiotic nitrogen fixation (chiefly biochemical) that have undergone considerable development in the last decade. Topics dealt with include the biochemistry of the bacteria in pure culture, the interaction of host plant and bacteria, the chemical mechanism of the fixation process, the effect of the carbohydrate-nitrogen balance in the host on fixation, excretion of nitrogenous substances from nodules into rooting medium, physico-chemical studies of possible enzyme systems, and a discussion of practical applications. A certain number of hitherto unpublished observations, views, and conclusions are included, and several hundred references are furnished, mostly to publications of the last ten years. The work is illustrated by numerous photographs and diagrams, most of which are of a high standard and amply fulfil their purpose. It is natural that a considerable proportion of the monograph should be devoted to the statement and consideration of results obtained in the Madison department, in view of the intensive investigations carried out there. Though he writes essentially for the specialist, Prof. Wilson treats his subject in as broad a fashion as possible. Thus in the introductory chapters passages are quoted from agricultural treatises dating from the opening of the Christian era. Anyone feeling this historical approach to be unnecessary would do well to note, as Prof. Wilson does, the complaint made by some modern investigators in this field that earlier workers thought of everything and anticipated many more recent "discoveries".

Prof. Wilson makes a notable attempt to reduce to some sort of order the seemingly chaotic results of studies on certain aspects of the subject, especially those relating to the excretion of nitrogenous substances from the nodules into the rooting medium. He has reached the conclusion that considerable differences may exist in the biochemistry of the same variety of leguminous plant and its nodules when grown under different climatic conditions. This extends to variation in the identity of the intermediates in the fixation process. The occurrence of excretion is considered to be dependent on a particular metabolic event — the accumulation of aspartic acid in the nodules. In this connexion the reviewer may perhaps be allowed to suggest that more attention might be paid by investigators at other stations to those original experiments of Prof. A. I. Virtanen in which the plants were grown practically by artificial light alone, still with the occurrence of excretion. In such experiments a degree of standardization of conditions may be achieved which is almost impossible if natural light is employed, and the investigation of factors of a non-climatic type is thus facilitated.

Prof. Wilson is endowed with a keenly critical mind, and does not hesitate to expose what seems to him to be faulty technique or reasoning. The result is that it is not unknown for him to be involved in disputes with other investigators, but few will quarrel with the view he expresses here that controversy is in fact desirable and useful, provided it avoids the acrimonious. It is indeed a tribute to Prof. Wilson's energy and perspicacity, with which the reviewer was previously acquainted, that this volume should have been produced without appearing to affect the output of original papers from the Madison department. In a lighter moment, Wilson and Fred subjected the vast literature dealing with leguminous nitrogen fixation to mathematical analysis, and concluded that an annual publication of approaching one hundred articles was soon to be expected, though it is probable that this rather fearsome climax has now been postponed. In this latest monograph we have a substantial addition to the 1940 quota of literature, but one which will be of great use to a variety of investigators. G. BOND.

THE ENGINEER'S YEARBOOK

The Engineer's Year-Book of Formulæ, Rules, Tables, Data and Memoranda for 1941
A Compendium of the Modern Practice of Civil, Mechanical, Electrical, Marine, Gas, Aero, Mine and Metallurgical Engineering. Originally compiled by H. R. Kempe and W. Hanneford-Smith. 47th annual issue, revised under the direction of L. St. L. Pendred. Pp. xii+2778+lvii. (London: Morgan Brothers (Publishers), Ltd., 1941.) 35*s.* net.

ONCE again, despite all the difficulties associated with war-time publication, "Kempe" has appeared and to all external appearances differs in no respect from its earlier issues. There is more in this than mere sentiment, for the publication of "Kempe" has become an important annual occasion in the engineering world. Originally designed by H. R. Kempe, engineer-in-chief at the General Post Office, to be a work which, being carefully brought up to date year by year, should take its place as the standard book of reference in the engineering profession, it has in actual fact attained to this eminence and fulfilled the destiny planned for it.

The 1940 edition, being the first affected by the present War, was subjected to some major alterations such as the elimination of the section dealing with costs, which had been rendered useless by the new conditions. In its place, the mathematical tables were reinstated, and it is in precisely the same form as that of its immediate predecessor that the 1941 edition has been issued. Last year the demand, instead of being smaller than usual as might have been anticipated, actually proved to be enhanced by the changed conditions, thus confirming the need for such a publication and the reliance which engineers have come to place upon "Kempe". The range of information packed into its many pages is amazingly wide, and, being well documented and backed by the high reputation of the men who have contributed its various sections, can be relied upon to yield most of the established data such as may at any moment be required by a practising engineer in one or other of the branches enumerated in the bibliographical particulars given above.

Two minor omissions should be made good in due course. In the section on belt conveyors an empirical formula for the power required to drive a conveyor of this type includes a term representing the weight of the belt; but no information appears as to the weight of such belts. Further, formulæ are given for the approximate strength of wire and manila ropes, but for cotton ropes for there are no such data.

EVERYDAY CHEMISTRY

An Introduction to Chemical Science
By Prof. W. H. Hatcher. Pp. viii+423. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1940). 18*s.* net.

THIS book is based on a course of lectures which has been developed over a period of years by the author in an attempt to give to non-scientific students at McGill University a cultural appraisal of chemistry.

The book is divided into four main parts, namely, inorganic, organic, food and industrial chemistry, and contains a bibliography and comprehensive index. In the first part, an introductory account is given of the non-metals and their more important compounds, and this, quite rightly, is blended with an elementary discussion of solutions, colloids and the atom. A broad survey of both metals and non-metals is also given in three chapters which are devoted to the classification of the elements.

Part 2 provides a satisfactory introduction to organic chemistry, a special feature being the number of large and well-printed structural formulæ. The non-specialist is helped by the omission of detailed descriptions of preparations and properties, although this commendable feature is rather marred by the naming of too many complex organic compounds.

The section on the chemistry of foods, Part 3, should be of particular interest at the present time to both scientific worker and layman because the relative values of various foodstuffs are compared. The chemistry of digestion is explained, as also are some of the mysteries of the kitchen. An elementary account is given of the vitamins, and this includes an interesting table of an adult's requirements of vitamins and the weights of different foodstuffs containing these quantities. Incidentally, the figures in the table refer to the *daily* requirement of an adult, but the author has omitted to mention this fact.

The final section of the book, Part 4, gives a simple but interesting survey of industrial chemistry. The sources and methods of obtaining the raw materials are first described, and then elementary details are given of the chemical processes whereby these raw materials are made to yield metals, acids, ceramics, refined oils, etc.

This volume, which is printed in large type and strongly bound, should prove a valuable addition to any library. The intelligent layman and the sixth-form pupil on the non-science side will find much of interest in the book, while chemistry teachers will find useful material in it for the preparation of their general science courses.

A. C. C.

MEASUREMENT OF TEMPERATURE

A Manual of Heat and Temperature Measurement
Compiled by Robert L. Weber. Pp. vii+141. (Ann Arbor, Mich.: Edwards Brothers, Inc., 1939.) 2.85 dollars.

Temperature Measurement
By Robert L. Weber. Pp. x+172. (Ann Arbor, Mich.: Edwards Brothers, Inc., 1941.) 2.50 dollars.

THE interest of these volumes lies chiefly in the light which they throw on the methods adopted in a progressive American university to give a practical course to those who will afterwards use scientific instruments in their work. Each book is in two parts, the first an outline of the subject, the second giving the laboratory notes for about twenty experiments.

In the manual of heat and temperature measurement, Part 1 would strike an English student as far too scrappy to be of any value except for revision: in twelve chapters, of an average length of 6 or 7 pages each, the subject of heat is dealt with. Chapter iv, on the other hand, occupying 15 pages (including a full-page photograph of the outside of a potentiometer indicator), compensates for these defects by giving a much fuller, helpful and critical account of thermocouples and their uses than would be found in a British text-book. Subsequent chapters deal sketchily with the theory and well with the practice of radiation pyrometry and resistance thermometry. There are very good chapters indeed on recording pyrometers and on automatic control of temperature. Part 2 of either volume would offer suggestions to many teaching institutions. The whole outlook is practical, and the experiments are well chosen to illustrate principles and yet to introduce the student to instruments likely to be used in his subsequent career.

The later book, on the other hand, deals more thoroughly with its less extensive subject. The outlook is admirably practical, and there are tables of the properties of thermo-electric metals and of refractories, in addition to other data which make the book of value to the worker in heat, as well as to those in the student stage. All branches of temperature measurement—including the extremely low and the extremely high—are considered, and such matters as flame temperature are not overlooked.

The books have been photographically reproduced from typescript, presumably with the figures gummed on to the copy, and the result is pleasing. They are bound in a limp cloth which seems likely to withstand student handling, and would well repay perusal, if not by students, at any rate by those who plan their courses of instruction. Many of the figures lack any informative value, and some are too dark to show any detail, but a pair on p. 101 of the later work, showing interference fringes caused by heated streams of air, are magnificent.

In each book there is an appendix of tables, larger in the 1941 book than in its predecessor, noteworthy among them being a compact table of the E.M.F. of thermocouples every 2° from 0° to as high as 1720° C., and occupying no more than a page.

THE SUN AS A PRODUCER OF ENERGY*

BY PROF. S. CHAPMAN, F.R.S.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

RADIANT AND GRAVITATIONAL ENERGY

THE existence of ionized layers in the earth's atmosphere is due to solar radiation, but in the *phenomena* of the ionosphere an entirely different cause plays a secondary part, namely, gravitation, exerted in the form of tidal forces, more by the moon than the sun.

The same two distinct causes provide the energy that electrical engineers develop and apply in so many ways. The sun's radiation is the chief source. Though engineering based on the direct use of the sun's heat is not yet practicable on any large scale, great use is made of past sunlight, stored up in the coal measures; and hydro-electric power comes from solar radiation of our own time, which raises water from the sea to the sky; it descends as rain, and some of this rain-water flows through turbines on its way from the highlands to the sea. A secondary source of energy is gravitational, namely, the sea tides, especially where these are magnified in narrow channels.

SOLAR ENERGY: THE GRAVITATIONAL THEORY

Helmholtz thought that ultimately these two sources were the same—that the sun's radiation is derived from potential energy of gravity which the sun once possessed in much larger measure than it does to-day. In his view the sun was formerly a sphere of rare cool gas, far larger than now; its self-attraction caused it to contract, and as the outer layers 'fell' inwards or 'downwards' towards the centre, the gas within was compressed and its temperature rose. Thus the sun gradually became hot, from the centre outwards. When the heat had spread to the surface, the sun became luminous, and its transformed gravitational energy was poured out as radiation.

On the basis of this theory Lord Kelvin concluded that the sun could not have shone with its present brightness for more than about 20 million years, and that therefore the geological changes and the evolution of life on the earth must have been limited to this period. Impressed by his authority, some geologists accepted his estimate; others, more independent in mind and more confident in their own data, rejected it; we know now that they were right.

THE SUBATOMIC SOURCE OF SOLAR ENERGY

These two great men, Helmholtz and Kelvin, were dealing with a real and important feature of the sun's power supply, but perforce they missed the main point, which was beyond the science of their time. The present output of solar energy is not of gravitational origin; it is produced in the central region of the sun, from subatomic energy, by a special type of combustion or chemical reaction.

The fuel is hydrogen, and of this the sun has large reserves, comprising about a third of its mass. The product of combustion is helium.

TERRESTRIAL AND SOLAR COMBUSTION

The solar combustion has interesting analogies with the burning of coal in a furnace, but in other ways it is remarkably different. In a coal furnace one carbon atom combines in successive stages with two oxygen atoms to form a complex molecule, carbon dioxide. The reactions are essentially of the form:

$$2C + O_2 = 2CO,$$
$$2CO + O_2 = 2CO_2;$$

and in the process energy is emitted in the form of heat. The burning begins only if the coal is first heated to a suitable temperature; its combustion then maintains this temperature.

The combustion in the solar furnace likewise produces one complex particle, a helium atomic nucleus, out of four simpler particles, in this case four hydrogen atomic nuclei; and in the process energy is emitted, mainly in the form of radiation of very short wave-length, namely, γ-radiation. The process begins only when the solar gas is raised to a very high temperature and density or pressure.

Herein lies the important part played by the gravitational contraction considered by Helmholtz and Kelvin; this produces the necessary temperature and pressure, twenty million degrees centigrade and ten thousand million atmospheres, near the centre of the sun. Thereafter the 'burning' of the hydrogen nuclei can maintain the temperature and prevent further contraction for thousands of millions of years, during which the sun radiates with at least its present brightness.

One may say that the solar furnace, like some types of internal combustion engine, was ignited by compression. Helmholtz mistook the brightness and the radiation leakage during the initial ignition process (occupying only a few million years) for the main and much more productive process of energy generation from subatomic sources.

---

* From the earlier part of the thirty-second Kelvin Lecture to the Institution of Electrical Engineers, entitled "The Sun and the Ionosphere", delivered on May 8.

ORDINARY MATTER AND NUCLEAR CRUSHED MATTER

In a coal furnace the atoms and molecules that take part in the combustion are electrically neutral systems. They consist of small positively charged nuclei, containing almost all the mass, with an outer structure of light negative electrons.

In the central solar furnace the outer structure of all atoms is broken up ; the gas therefore consists of free nuclei and free electrons. This 'crushed matter' is much more compressible than ordinary matter, and at the centre of the sun its density is about eighty-five times that of water.

Thus the combustible part of the central gas consists of hydrogen atomic *nuclei* (also called protons). These combine to form helium atomic nuclei (also called α-particles). The negative electrons present play no direct part in the combination.

THE MAIN REACTION IN THE SOLAR FURNACE

In a coal furnace oxygen is as essential to the combustion as the coal itself, and two atoms of oxygen (or one molecule) lose their separate existence for each carbon atom 'burnt'. The oxygen has an equal right with the carbon to be considered as fuel, though because it costs nothing we may ignore this.

In the solar furnace the fuel is hydrogen nuclei or protons. But these do not combine together directly ; they are built up into helium nuclei in the course of a six-stage reaction involving a catalyst. The catalyst is a particle that undergoes a cycle of successive transformations but is left finally unchanged. At the outset of the helium-building reaction, the catalyst is an ordinary carbon nucleus ${}_6\mathrm{C}^{12}$[†] ; it undergoes four successive combinations, with one proton at a time ; two of its intermediate forms are unstable, and undergo a spontaneous radioactive transformation, with the emission of a positive electron. The outcome of the fourth combination is a helium nucleus and an ordinary carbon nucleus as at first. The helium nucleus has been synthesized from the four protons, and the carbon nucleus is ready to start another such reaction cycle.

The equations of the six nuclear-chemical reactions are as follows, where I have added a + sign to the suffix as a reminder to the reader that the suffix indicates the number of elementary positive charges possessed by the particle ; also e_+ denotes a positive electron carrying one positive charge, and of very small mass. In each equation the sum of the suffixes on the two sides are the same, and likewise the sum of the affixes ; these equalities correspond to the conservation of charge and of mass.

2½ million years

$${}_{1+}\mathrm{H}^1 + {}_{6+}\mathrm{C}^{12} = {}_{7+}\mathrm{N}_{13} + \text{gamma ray}$$

10 minutes

$${}_{7+}\mathrm{N}^{13} = {}_{6+}\mathrm{C}^{13} + e_+$$

50 thousand years

$${}_{1+}\mathrm{H}^1 + {}_{6+}\mathrm{C}^{13} = {}_{7+}\mathrm{N}^{14} + \text{gamma ray}$$

4 million years

$${}_{1+}\mathrm{H}^1 + {}_{7+}\mathrm{N}^{14} = {}_{8+}\mathrm{O}^{15} + \text{gamma ray}$$

2 minutes

$${}_{8+}\mathrm{O}^{15} = {}_{7+}\mathrm{N}^{15} + e_+$$

20 years

$${}_{1+}\mathrm{H}^1 + {}_{7+}\mathrm{N}^{15} = {}_{6+}\mathrm{C}^{12} + {}_{2+}\mathrm{He}^4$$

Preceding the line for each reaction a time is stated ; this is an estimate of the time that elapses, under the conditions existing in the solar furnace, before the reaction occurs ; Bethe, to whom this theory and these estimates are due, states that the times may be wrong by a factor 3 either way, except the shortest two, which are based on observation in the laboratory. The three long intervals illustrate the rarity of combinations at which two nuclei combine to form a single particle with the emission of the excess energy as radiation ; this occurs only when the collision satisfies certain highly restrictive conditions. Hence the last combination, in which two particles, without radiation, result from the collision of two other particles, is far more probable than the possible alternative

$${}_{1+}\mathrm{H}^1 + {}_{7+}\mathrm{N}^{15} = {}_{8+}\mathrm{O}^{16} + \text{gamma ray.}$$

The equations show that it takes a few million years for any one carbon nucleus, fertilized by four successive protons, to bring to birth one α-particle. If the birth-rate is high at the centre of the sun, it is because the number of carbon atoms and protons there is immensely great.

[†] The chemical nature of an atomic nucleus is determined by the number of (positive) elementary charges that it carries ; for hydrogen, helium, carbon, nitrogen and oxygen nuclei these numbers (called the *atomic numbers*) are respectively 1, 2, 6, 7, 8. The nucleus is conveniently denoted by the appropriate chemical atomic symbol together with a suffix indicating the atomic number or number of positive charges (though either the number or the atomic symbol would suffice, as the atomic number uniquely determines the symbol). Thus the nuclei of hydrogen (a proton), helium (an α-particle), carbon, nitrogen and oxygen are denoted by ${}_1\mathrm{H}$, ${}_2\mathrm{He}$, ${}_6\mathrm{C}$, ${}_7\mathrm{N}$, ${}_8\mathrm{O}$. The mass of the nucleus is not uniquely determined by the charge or atomic number; nuclei of different masses but the same charge are called isotopes. The atomic mass may conveniently be indicated by an upper integer affix, equal (very nearly) to the chemical *atomic weight*. Thus a proton and an ordinary α-particle are denoted by ${}_1\mathrm{H}^1$, ${}_2\mathrm{He}^4$, and the isotopes of carbon, nitrogen and oxygen that occur in the solar central reaction are ${}_6\mathrm{C}^{12}$, ${}_6\mathrm{C}^{13}$,${}_7\mathrm{N}^{13}$, ${}_7\mathrm{N}^{14}$, ${}_7\mathrm{N}^{15}$, ${}_8\mathrm{O}^{16}$; of these ${}_7\mathrm{N}^{13}$ and ${}_8\mathrm{O}^{15}$ are unstable.

THE ENERGY PRODUCTION

The catalytic combination of hydrogen nuclei is enormously productive of energy. Whereas the ordinary combustion of 1 lb. of coal gives heat energy equivalent to $4\frac{1}{4}$ electrical units, the 'burning' of 1 lb. of hydrogen nuclei produces radiant energy equivalent to nearly 100 million electrical units.

Energy has mass, though only 1 gram to 25 million electrical units; hence the radiant energy produced from 1 lb. of hydrogen nuclei has a mass of 4 gm.; the mass of the resulting helium nuclei falls short of 1 lb. by this amount—a perceptible diminution.

Helios, the sun, is a power producer on the grand scale. Its heating and lighting output is nearly half a billion billion kilowatts (more exactly, $3{\cdot}8 \times 10^{23}$ kw.), and I use billion in its English sense, to signify a million million. The corresponding loss of mass is at the rate of 4 million tons per second.

THE OUTWARD STREAM OF RADIANT ENERGY

This energy is generated in the central solar furnace mainly as gamma radiation. This struggles upwards through the immense surrounding mass of overlying gas, ever cooler and less dense the farther from the centre. The radiation is continually degraded in frequency or increased in wave-length, and finally it leaves the sun with a spectral distribution corresponding roughly to a temperature of 6,000° C. It consists of electromagnetic waves the average frequency of which is still very high, nearly a billion kilocycles per second. As it reaches the earth and other distant consumers, it is highly directional.

SOLAR SURFACE PHENOMENA

In the upper layers of the sun the stream of outward flowing radiation energizes many surface phenomena on a grand scale. Of these the most evident are the sunspots and prominences. Much of the solar gas that we see raised above the surface in the form of prominences falls back again on to the sun, but some of it is expelled never to return. Thus the sun sends forth matter, as well as electromagnetic radiation, into the space around it. The matter, in the form of clouds or streams of rare gas, is a partner with the solar wave radiation in ionizing the earth's outer atmosphere.

ENERGY SUPPLY TO THE EARTH

Of the sun's majestic outpouring of radiant and material (kinetic) energy, all but a tiny fraction is lost in the depths of interstellar space. The father Helios scatters his riches abroad with grand prodigality, and his children the planets intercept only the merest scrap of their patrimony. Our mother earth receives less than a thousand millionth of the parental output (more exactly, the fraction is $4{\cdot}5 \times 10^{-10}$). Yet her income of over 170 billion kilowatts is not small.

All this income she spends, and perhaps a little more, drawn from her own reserves. Very little of her income can she store up for the future. From one point of view, the history of the earth since she became a separate planet is largely the story of the spending of her solar income.

INTERACTION OF VITAMINS A AND E

By A. W. Davies and Dr. T. Moore

Dunn Nutritional Laboratory, Cambridge

ONE of the most noteworthy properties of vitamin A is the extent to which it can accumulate in the liver. When the dietary intake is liberal, sufficient vitamin may be stored to meet ordinary requirements for a theoretical period of about a hundred years[1]. Some years ago we began experiments to find whether during a subsequent deficiency these large reserves would in practice be preserved and used up economically at a rate corresponding with physiological requirements, or whether they would be dissipated at an unduly rapid rate. In our first experiment a rapid dispersal of the vitamin A reserves was observed[2]. We emphasized, however, that this result was exceptional, since in earlier work large reserves had been found in the livers of rats after prolonged restriction to deficient diets[3].

For several years we tried to repeat, and explain, our observations on the rapid loss of vitamin A, but with unsatisfactory results. The influence of the exact nature of the basal diet was specially considered, and many minor modifications were made without affecting the rate of disappearance of the vitamin. Eventually a clue was obtained from an unexpected direction when it was found that the vitamin A reserves of rats which had been kept on a diet deficient in vitamin E were much lower than those of animals receiving equal amounts of vitamin A together with supplements of vitamin E[4].

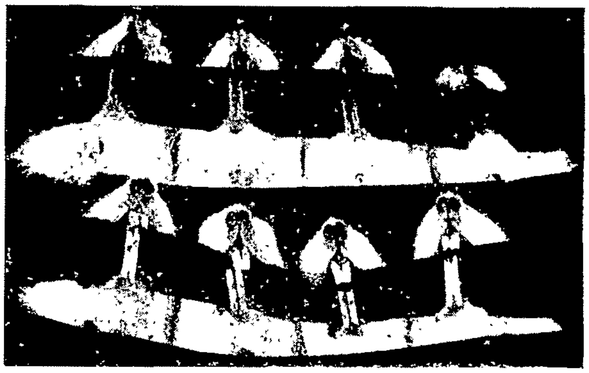
Further unpublished experiments on this point have shown that the effect in vitamin E deficiency does not lie entirely in the inability of the liver to absorb vitamin A, but also in a decreased power of retention after absorption. In the experiments to be described we have found that, under suitable conditions, deficiency of vitamin E may lead to acute secondary deficiency of vitamin A. The exhaustion of the reserves in the liver has been established directly by chemical tests. Further indirect evidence of secondary deficiency of vitamin A has been found in the appearance in the rats deficient in vitamin E of a dental abnormality hitherto ascribed to primary deficiency of vitamin A.

During a preparatory period of several weeks, young female albino rats were given an adequate mixed diet, supplemented by large doses of halibut liver oil. At intervals some of the animals were killed, and the reserves of vitamin A in their livers were estimated by the antimony trichloride method. When large reserves had been accumulated the animals were divided into two groups. Both these groups now received a basal diet deficient in both vitamins A and E (casein, Glaxo extracted 20 per cent, sugar 70 per cent, lard 5 per cent, salt mixture 5 per cent plus dried yeast 10 per cent, Radiostol, for vitamin D, 1 drop per rat per week). One group was given doses of vitamin E, in the form of 1 mgm. weekly of synthetic *dl*-α-tocopherol acetate. The other group had no vitamin E. Animals from each group were killed at intervals, and the vitamin A reserves estimated. The results obtained are shown in the accompanying table.

Days on diet deficient in vit. A and E	Vitamin A Reserves (I.U.)		Notes
	+ vitamin E	− vitamin E	
0	15,000		Rats killed after prolonged dosing with halibut liver oil before the remainder were restricted to a diet deficient in vitamins A and E
	15,000		
	15,000		
	22,500		
	22,500		
	30,000		
	mean 20,000		
28	15,000	15,000	Uteri of − E group still normal in colour
	18,000	15,000	
	30,000	18,000	
	37,500	18,000	
	mean 25,000	mean 16,500	
91	9,000	3,700	Uteri of − E group light brown
	12,000	4,500	
	15,000	4,500	
	15,000	6,000	
	mean 13,000	mean 4,700	
222	3,750	5	Uteri of − E group dark brown, teeth white
	6,000	6	
	6,000	9	
	7,500	15	
	mean 5,800	mean 9	

N.B. Growth was slightly more rapid in the + E than in the − E group. The mean initial weight of the + E rats which survived 222 days was 132 gm., the final weight 212 gm. The mean initial weight of the corresponding − E rats was 139 gm., the final weight 171 gm. During the last 100 days of the experiment the − E rats declined slightly in weight, and the fat reserves at autopsy were sparse.

In both groups the rate of loss of vitamin A exceeded that calculated from the presumed physiological requirement. An allowance of 10 I.U. per day should be sufficient for rapid growth in adolescent rats. On this basis not more than about 2,000 I.U. should have been used up in the animals kept on the deficient diet for 222 days, as compared with a minimum actual loss of 14,000 I.U. There was, however, a consistent difference between the two groups. At all stages of the experiment the vitamin A reserves of the rats given tocopherol were greater than those of rats which had no vitamin E. After restriction to the deficient diet for 222 days the reserves of the animals having tocopherol were still high, the mean total reserve being 5,800 I.U. The reserves of the untreated group were too low for accurate measurement, the mean being 9 I.U. The faint traces of colour given by the liver oils of this group, moreover, were not of the usual bright blue shade but a dull purple, similar to that given by preparations of vitamin A after partial destruction by oxidation. It is therefore doubtful what proportion of the colour can be attributed to unchanged vitamin A.



Top row, + vitamin E, normal teeth; bottom row, − vitamin E, white teeth

At autopsy evidence of vitamin E deficiency in the rats not given tocopherol was obtained by inspection of the uteri. In the groups killed after 91 and 222 days of deficiency the brown discoloration described by Martin and Moore[5], which is characteristic of deficiency of vitamin E in the rat, was always observed. The uteri of animals protected by tocopherol were all normal in colour.

Another striking difference between the two groups was seen in the teeth, which were of the normal brown colour in the group given tocopherol, but almost white in the untreated group (see accompanying illustration). Whitening of the teeth in vitamin A deficiency has been studied by several investigators[6,7,8,9]. According to H. Mellanby[10] the changes can be explained as arising primarily from a metaplasia of the epithelial cells of the enamel organs, which leads to secondary changes in the odontoblasts and dentine. If this conclusion is accepted, and the relation between whitening of the teeth and deficiency of vitamin A is regarded as specific, it is clear that the appearance of this abnormality in the untreated group affords additional evidence of the occurrence of secondary vitamin A deficiency. In our experience however, partial whitening of the teeth may occur in rats which are deficient in vitamin E, but which still have considerable reserves of vitamin A in their livers. We have also occasionally observed brown teeth in rats which have died from deficiency of vitamin A. It may possibly be better, therefore, to regard this lesion as a common effect of deficiency of either vitamin.

Sections of the tracheæ of the rats not given tocopherol were examined, but only in one instance was the normality of the epithelium open to question.

In the above experiment we have achieved the apparent paradox of preventing deficiency of one vitamin by the administration of another vitamin. In the absence of full data on the effect of deficiency of other vitamins we cannot decide how far the role of preserving the vitamin A reserve is peculiar to vitamin E. We know, however, that the vitamin A reserves are not much reduced in deficiency of the vitamin B complex[3] or in prolonged deficiency of protein so severe as to cause emaciation and complete cessation of growth in young rats[4]. Some support for the possibility of a specific interaction between vitamins A and E may be derived from a consideration of their chemical properties. The tocopherols are higher substituted members of the class of hydroxy-aromatic substances of which hydroquinone is a lower and less hydroxylated member. This substance is often used for stabilizing solutions of vitamin A in fats. The tocopherols may possibly have a similar action under physiological conditions.

The present results explain the rapid loss of vitamin A reserves observed in our early experiment[2] if we assume, as seems highly probable, that the basal diet used on that occasion was unintentionally deficient in vitamin E. Our knowledge of the role of vitamin E in human nutrition is too scanty to allow speculation as to whether the present findings have any clinical significance. From estimations of the vitamin A reserves of humans at autopsy, however, we know that secondary subnormality of vitamin A is common and sometimes severe. Thus the medium reserves for forty cases of chronic nephritis was found to be 25 I.U. per gm. of liver as compared with 220 I.U. per gm. in accidental death. Any factor, such as vitamin E deficiency, which causes secondary vitamin A deficiency in experimental animals must be worth consideration in the investigation of human diseases in which the reserves of vitamin A are known to be reduced.

SUMMARY

(1) In rats restricted to a diet deficient in both vitamins A and E the reserves of vitamin A were used up much more rapidly than in control animals given *dl*-α-tocopherol.

(2) Prolonged deficiency of vitamin E led to secondary deficiency of vitamin A, as indicated by the disappearance of this vitamin from the liver. The deficient rats also developed the whitening of the teeth which is generally held to be an effect of deficiency of vitamin A, but which may perhaps be considered a common result of deficiency of either of these vitamins.

Our thanks are due to Dr. L. J. Harris for his valuable criticism, and to Roche Products Ltd., for gifts of *dl*-α-tocopherol.

FEEDING DRIED NETTLES TO LIVESTOCK

By W. KING WILSON,
HARPER ADAMS AGRICULTURAL COLLEGE

THE quantity of stinging nettles grown unwillingly throughout Great Britain must amount to a very considerable weight of material each year. What is its food value ? According to average figures for the chemical composition of dried nettle leaves, they compare very favourably indeed with hay of good quality and would appear to be as good as clover, lucerne or sainfoin in their content of protein, while the fibre is generally shown to be lower in nettles than in hay, even when the latter is of a very good grade.

Furthermore, digestion trials have shown that nettle leaves are highly digestible and in this respect also rank with the best species and grades of hay. Although fibrous in character, they are nevertheless well utilized by animals which normally have only low powers of digesting fibre, such as the pig, fowl and rabbit. Nettles mixed with straw chop have been used effectively in feeding cows and horses, but the amounts available are usually better suited for use with small livestock, and it is with these that experiments have usually been made. Such experiments were carried out in Germany[1] and gave results for digestibility which were somewhat better with nettles than with lucerne hay, and conspicuously better than with meadow hay. The figures for the total organic matter digestion coefficients were 63, 61 and 47 per cent respectively, while the comparison was even more favourable for the separate items of protein and fibre.

As these digestion trials were carried out with rabbits, even more favourable results might be expected with ruminants[2], since they are specially adapted for digesting fibrous foods. Judged by these results, and assuming that livestock will eat nettles freely, it would seem desirable that more use should be made of this common weed as fodder—and indeed it might even be better worth growing for hay than inferior grass. There seemed at least to be a sufficient warrant for the small-scale tests described below, which were carried out in the Rabbit Department of the National Institute of Poultry Husbandry.

PALATABILITY OF NETTLES (DRIED)

A few tests of the palatability of nettles may first be noted: The rabbits were kept in sheds with grass runs adjoining, where the grass was closely grazed until there was none left in the summer time and additional green food had to be fed. Even when the runs were bare of grass, the animals did *not* eat the stinging nettles when the nettles were growing even when they were very short, young and leafy. This result was obtained each year, and was checked in the past season with thirty more animals; these animals were kept short of green food, but only slight nibbling could be induced on a few of the growing nettles. The nettles were then mown and left on the ground, where they remained, and normal feeding was resumed. During the following month all the dried-up nettles were eaten, including the stems. (It will be noted that this is exactly the reverse process from inducing stock to eat the common thistle, for thistles should be young and tender if they are to be eaten by stock.) More nettles were cut and made into hay before reaching the flowering stage; less turning was necessary than is usual with hay, owing to their stalky nature when cut. Later, the dried nettles were fed to ten adult rabbits in hutches, and although at first two refrained from eating them for two and for three days respectively, they all ate them readily after the first few days. Feeding continued as with normal hay and they were evidently a palatable food.

A further supply of stinging nettles was cut, but as the weather then seemed unsettled and rain likely, these nettles were carted indoors about the third day. These were fed to ten young hutched rabbits at the half-grown stage, but this lot practically refused them after nibbling the first few pieces. The rest of the ration was then curtailed, but none of these young animals would clear up the nettles. The only noteworthy difference in this nettle hay was that it was cut later and carted before it was as well made as could be wished for; it was, however, a good green colour. When this was handled, it gave a decidedly tingly or irritating sensation; that is, it retained some of its sting, which had practically disappeared in the better-made earlier-cut nettle hay which had been kept ten days or more.

EXPERIMENTAL

With the guidance of the foregoing preliminary observations, an experiment was started with nettles cut and dried for 3–4 weeks: twenty young rabbits, approximately two months old, were divided into two similar groups and fed for eight weeks on a mixed diet of greenfood, roots, mash and hay. The first group, acting as the control, received the usual grass hay available from poultry runs. This was mainly composed of the coarser grasses including cocksfoot, and generally of a low grade. The other group was fed on a similar ration except that grass hay was replaced by an equal weight of dried stinging-nettles—after they had lost their sting—cut before the flowering stage. Care was taken to use nettles which were free from grass or weeds. The quantities of food were kept level in both groups, although it was soon noticed that the nettle group consumed their hay quicker than the lot on the coarse grass hay. As the stock grew older, the amount of food was increased but only to the level at which the grass hay group would clean up their ration. The amount of foodstuffs used daily for these small youngsters started off at a daily average per head of: 0·71 oz. of hay, 2·64 oz. kale and swedes and 1·48 oz. of dry mash. Water was drunk at the rate of 0·10 pint per head daily. The quantities of food were increased in the following month to 1·03 oz., 3·09 oz. and 2·01 oz.; this was the rate at which the controls cleared up their daily allowance but appeared to be less than the nettle group would have taken if allowed an unrestricted diet. In the following weeks it became even more noticeable that the nettle group finished its food more quickly than the grass hay group. There was a tendency for the latter to be troubled with intestinal obstruction when very rank hay was used.

The animals were weighed at regular intervals, and at one month after this feeding started there was a perceptible difference in the condition of the two groups, which became more evident as the length of the feeding period increased. In the early weeks, body condition and coat were rather better on nettles and, as the system continued, the live weights illustrated the definite advantage of feeding nettle hay compared with coarse grass hay, as the nettle-fed stock weighed on the average 8·7 per cent heavier than the controls. If expressed as a percentage gain over the controls, it amounted to 17·0 per cent. They were very hard and firm when handled, and tighter in the skin than controls.

Data for the two groups are set out below:

The quicker growth and heavier weights of the nettle-hay group showed a further advantage in the ratio of food consumption per pound gain i live weight. There was a saving of 15·56 per ce in the amount of concentrates used for each pou of live-weight gain when fed with nettle hay. Th

BODY WEIGHT AND CONDITION (OZ.)

Group:	Grass Hay	Nettle Hay
Initial live weight, average	27·10	27·10
Final live weight, average	55·30	60·10
Average live weight gain	28·20	33·00
Difference in gain, as percentage of gain made by control	—	17·02
General body condition, at final weighing	Quite good	Excellent
General coat condition, at final weighing	Moulty and rough	Moulty, but gloss and silky texture

glossy coat produced by the nettle feeding is special interest, since the same effect has bee claimed for nettles when fed to horses.

Acknowledgement is made of the advice a assistance received from Dr. Charles Crowther.

OBITUARIES

The Right Hon. Lord Cadman, G.C.M.G., F.R.S.

THE very complete biographies of the late Lord Cadman, who died on May 31 at the age of sixty-three, that have appeared in the Press render it unnecessary to deal with his multitudinous activities here.

It is rather the intention of the writer to throw into relief his achievements as a man of science, and it is more than likely that it is just this aspect of his life that Lord Cadman would have wished emphasized.

After more than twenty-five years of close association with him, it is apparent that the scientific approach to industrial problems had assumed an overwhelming importance. In all the wide gamut of the petroleum industry from the initial geophysical exploration, the geological demarcation of oil-bearing formations, the technology of drilling, the corrosion of pipe-lines and plant and ships to the chemistry of refining processes, his fluid and prehensile mind was fully occupied and extended. There was probably no one man of our epoch with the same encyclopædic knowledge and, what is more important, the same wide and active sympathy with those who were associated with him as his scientific colleagues.

In his younger days Cadman was primarily a 'coal' man. At the age of twenty-six he was appointed H.M. Inspector of Mines for East Scotland and very shortly after was seconded to Trinidad as Government mining engineer. It was in this position that he encountered the multitudinous problems of the petroleum industry. Returning to England in 1907, he became professor of mining in the University of Birmingham, a post he held for thirteen years, during which time he founded the first school of petroleum technology to be established in the Empire and was professor emeritus at t time of his death. It was in Birmingham that h close collaboration with his old friend, the late Pr J. S. Haldane, began, and a fruitful series of investigations into various mine hazards was accomplishe In the War of 1914–18 he was intimately concerne in the problems of trench warfare and of gas protection. Ultimately he was made director of th Petroleum Executive and chairman of the Int Allied Petroleum Council. He co-ordinated all supplies both for the United Kingdom and the Alli During these busy years and for long afterwar he retained his interest in the scientific and techni aspects of industry, served on innumerable c missions and committees and occupied the presiden chairs of the Institute of Petroleum, the Institute Fuel and the Institute of Mining Engineers.

He received the medals awarded by the latter tw bodies. He served on the Advisory Council of t Department of Scientific and Industrial Research the Privy Council, the Safety in Mines Resear Board, the Coal Advisory Council and the Pri Minister's Economic Advisory Council. He was member of the Fuel Research Board from 1923 un his death, except for a short break of four year During the time he was a member of the Board, was intensely interested in the work and took prominent part in the discussions in the Boa Although he was so intimately associated with c his association with the coal industry had left hi with real sympathy with the subject, and he nev hesitated to use his influence to further the scienti application of coal. He continually advocated t complete gasification of coal so that cheap gas co be made accessible in large volumes in Great Britain. He also took a great interest in the production of ptor spirit from coal by the hydrogenation process. he coping stone of his scientific career was placed ly last year by his election to the fellowship of the yal Society.

As one of his oldest colleagues, the writer wishes to ess Cadman's perpetual insistence that no industry n flourish that is not soundly based on truly ientific foundations. In the Anglo-Iranian Oil ompany he fostered research. He was responsible r the creation of the largest petroleum research ation in the Empire and one that will bear every mparison with corresponding organizations abroad. e was deeply sensible of the need of the latest and est scientific advice. He supplemented the efforts f his own staff with those of highly skilled and minent advisers. He continually visited the lab- atories and took the keenest interest in the welfare nd well-being of his staff. In return he was rewarded y a constant stream of invention, discovery and development.

A. E. DUNSTAN.

Dr. R. Campbell Thompson, F.B.A.

REGINALD CAMPBELL THOMPSON died of heart lure after coming off duty with the Home Guard the night of May 23. He was the last repre- ntative in England of a phase of Assyriology hich converted that study from a discovery into science. When he was a boy at St. Paul's, he was attracted, by the results attained by the early Assyriologists during the heroic days which had pened with the measured judgment on translations submitted by four different scholars in 1842, by a committee which did not profess to understand the text translated. By the time he reached aius College, Cambridge, the *epigoni* had been busy or some fifteen years producing grammars, diction- ries, catalogues of tablets; the exciting work of ecipherment and interpretation on the lines of Sir enry Rawlinson, George Smith, Oppert and Sayce as becoming a science and was a subject favoured German, but not by English, or even French, niversities. When he entered the British Museum n 1899, already well equipped for Assyriological udies, the ground had been prepared for the classi- cation of Babylonian and Assyrian texts, for ethodical publication of texts by classes and for he codification of results.

For forty years Thompson contributed, sometimes th the brilliant success of the pioneers he most lmired, but also by steady and laborious work, to he new conditions of his chosen subject. Between 900 and 1908 there appeared in the official publica- ion of the British Museum copies from his pen of abylonian syllabaries, magical incantations against vil spirits, Babylonian letters of the late period, ach class of document arranged after examination f great numbers of tablets and fragments, all the opies in beautiful script, the standard of accuracy emarkable. In addition to this great output, he lited, in private publications, texts dealing with trology, magic and social life. In each of these branches, more particularly in astrology, his work was of outstanding importance, for he was able to discard much worthless nonsense that had been written on the subject and produce an interpretation of the astronomical phenomena involved, on which subsequent studies have been firmly based. He then turned to the study of comparative religion; his volume on "Semitic Magic", though affected by prejudices and questionable preconceptions, contains information not to be found elsewhere, which ought not to be neglected by younger scholars as it has been.

After the break caused by travel when he left the British Museum, and by service in Intelligence during the War of 1914–18, Campbell Thompson's principal scientific work was concentrated on the publication and interpretation of those Assyrian texts which contained prescriptions for the sick, in the form of omens, or recipes for making glazes of glass. After publishing the original texts of most of the documents himself, he undertook the strenuous labour of classifying and interpreting the names of plants and stones, using for this purpose the scattered references in the wide range of cuneiform literature, and applying comparative material that required minute study. In two books, the "Assyrian Herbal" and the "Dictionary of Assyrian Chemistry and Geology", he provided two model works for the history of science, which have indeed been heavily drawn upon by general writers on that subject. The collection of material is beyond praise, the interpretations suggested always reasonable, most often correct, sometimes brilliant in their insight. These two works constitute Thompson's great contribution to humane learning, and it is the more to be regretted that owing to circumstances he was not able to see a printed edition of his "Assyrian Herbal" to press; the fitting tribute to him would be that such an edition should yet appear.

He was a man of many-sided interests, of boundless energy and enthusiasm. His chapters in the "Cambridge Ancient History", vols. I–III, give the liveliest, most human picture of the ancient Babylonian civilization yet written. His translation of the Gilgamesh Epic, following an excellent edition of the text which involved a new examination of the British Museum collections, betrays the same zest in the human quality of the story. As a traveller, he loved the manners and methods of the past, and aimed at describing his experience in the words of the past, as in "Pilgrim's Scrip" (1915). Excavations at Carchemish, at Wadi Sarga in Egypt, at Nineveh, were an adventure, conducted in that spirit to shock the over-serious or dull-witted. An undeciphered script, the Hittite hieroglyphs, he attacked with an optimism justified in that he was able to produce results still accepted in part. Prize poems and anonymous novels were part of his activities, and so were yachting and games.

Thompson was a fellow of Merton, Shillito reader in the University of Oxford, and fellow of the British Academy. No one who met him could fail to recognize his sterling qualities, honesty, energy, disinterested devotion to his subject.

SIDNEY SMITH.

NEWS AND VIEWS

The British Council Science Committee

THE British Council was formed in 1934. Under its charter, its object is defined as the promotion of a wider knowledge of Great Britain and Northern Ireland, and the English language abroad, and the development of closer cultural relations between the United Kingdom and other countries. The Council has already established many institutes abroad, and has active departments concerned with fine arts, music, drama, education, films, foreign visitors and students, books and other subjects. It has now formed a Science Committee under the chairmanship of Sir William Bragg. The other members of the Committee are Prof. P. M. S. Blackett, Prof. J. D. Cockcroft, Sir Robert Robinson, Dr. C. F. A. Pantin, Sir Edward Mellanby, Surgeon Rear-Admiral Gordon Gordon-Taylor, Sir William Larke, Sir Edward Appleton, Dr. A. P. M. Fleming, Mr. C. D. Le Maistre and Prof. R. V. Southwell.

Mr. J. G. Crowther has been appointed secretary of this Committee. Mr. Crowther is well known as the scientific correspondent of the *Manchester Guardian*, and has for many years been associated with the publication of scientific books. He is the author of fourteen general books on science, the most recent being "The Social Relations of Science". His book on "British Scientists of the Nineteenth Century" is also well known. Mr. Crowther has visited and written about many scientific institutions in Europe and America, and in 1937 he was invited by President Conant to deliver a course of lectures at Harvard University on the history of American science.

Bedford College, London: Chair of Zoology

PROF. H. MUNRO FOX, who succeeds the late Prof. C. L. Boulenger as head of the zoological faculty at Bedford College, London, has had a varied career. He was educated at Brighton College and Caius College, Cambridge, proceeding to the Imperial College of Science and Technology, London, as lecturer in 1913. In 1914, he enlisted in the London Mounted Brigade, in which he served until 1919, for the most part in Egypt and Palestine. In 1919 he became lecturer in biology at the School of Medicine, Cairo, leaving in 1923 to become demonstrator in zoology at Cambridge. He was already a fellow of his College and in the following year he was elected to the Balfour studentship. He then proceeded to the Suez Canal, where he investigated the fauna and conditions in relation to migrations between the Mediterranean and Red Seas, a survey which it is hoped may be repeated in 1950. The lunar periodicity in the breeding of marine animals was his discovery. In 1926 he started the *Biological Reviews* of the Cambridge Philosophical Society, of which he is still editor.

Prof. Fox's chief interest throughout his career has lain in the comparative physiology of respiration, the pigments concerned, the effects of environmental conditions, the circulatory system and respiration, especially in the marine worms. Later he investigated the properties of chlorocrurin, which has a low oxygen affinity, and its physiological relationships to the queer animals in which it is found. In particular, he was concerned with the serpulids and sabellids, in which he discovered an in-and-out circulation comparable to that which Galen supposed to exist in the human body.

Royal Anthropological Institute Awards

THE Rivers Memorial Medal for 1941 has been awarded to Dr. Diamond Jenness, ethnologist in the National Museum of Canada, for his work among the Eskimos of Arctic America. Dr. Jenness is a graduate of the Universities of New Zealand (1908) and Oxford (1911), and in 1935 was made an honorary Litt.D. of the University of New Zealand. Before being appointed in 1913 to his present post in the National Museum of Canada, he carried out field work in Papua; his principal work, however, has been among the Eskimos and Indians of North America. He took part in the Canadian Arctic Expedition of 1913–18, when he visited the Copper Eskimos; since then he has studied the Sarcee Indians of Alberta, the Carrier, Sekani and Coast Salish tribes of northern British Columbia, the Ojibwa Indians of Ontario, and has made expeditions to the Bering Straits and to Newfoundland.

The Wellcome Medal for 1940 has been awarded to Dr. Audrey I. Richards for her essay on "Bemba Marriage and Present Economic Conditions". After studying at London and Cambridge, Miss Richards was appointed lecturer in social anthropology at Bedford College for Women, and later she went to the London School of Economics. During 1934–38 and until recently she held a similar post in the University of the Witwatersrand. Dr. Richards has been especially interested in social anthropology of the functional type, particularly in psychological problems and in general problems of nutrition. In pursuit of her studies, she has made numerous expeditions to tribes in Northern Rhodesia.

Mr. Roosevelt and Oxford

Two striking parallel ceremonies took place at Harvard on June 19. Lord Halifax, British Ambassador to the United States, was given the honorary degree of doctor of law of Harvard University, and in his capacity of chancellor of the University of Oxford, he presided at a special Convocation, in which he conferred the degree of D.C.L. on President Roosevelt. Mr. Roosevelt was advised, on account of his temporary indisposition, not to make the journey from Washington to Harvard, but his friend and military *aide*, General Edwin Watson, represented him and delivered a stirring message of acknowledgment. In the Latin diploma granting the degree prepared for the occasion, reference was made to the heartening words with which Mr. Roosevelt has encouraged the defenders of liberty and to the material aid which he has given, and in ever-increasing measure is giving, to secure the defeat of lawlessness and aggression among nations, and to the stand he is making for liberty, humanity and law. Mr. Roosevelt's message mentioned the historic precedent of this special Convocation, expressing his pleasure that it "does so in the great cause of preserving the free learning and civil liberties which have grown stone upon stone in our lands". He concluded with the epigrammatic words: "We and all others who believe as we do would rather die on our feet than live on our knees."

A Dynamic Civilization

IN his presidential address "Industrial Progress, Whither and Why", before the Birmingham Metallurgical Society on March 8, Mr. C. H. H. Franklin pointed out that we are living in an epoch of dynamic change, and that whether we evolve into the finest civilization humanity has known or relapse into barbarism comparable with the Dark Ages of Europe after the fall of Roman civilization, is the principal issue. He urged that the future of industry, as of nations and of men, is being decided on the fundamental issues of free mutual co-operation, versus exploitation and compulsion. The organization of an animal or human structure provides valuable clues to the organization of our communal life, and he stressed the necessity of developing a team spirit in our industries and the concept of service of human and social needs if we are to extirpate the cancerous growth at present spreading in Europe and Asia and threatening all humanity. We need also to develop the technique of generating appropriate financial currents for human utility and service instead of its enslavement.

Mr. Franklin referred to the necessity of clarifying our concepts of the laws of growth, of change and of evolution, and of obtaining correct and not superficial answers to the questions of what we are making things for or why we are doing them in our present way. An individual or organization which reaches a stage where its sole concern is continuing its own existence is ripe for decay and dissolution. A great industrial city should display relics of its own industrial growth and models which show what has been and can be done. The deficiencies of past utensils have stimulated the desire and attempt to develop new materials which avoid these drawbacks. Referring to the new materials placed at our disposal by metallurgical progress, Mr. Franklin emphasized the importance of cooking utensils, and suggested that the most appropriate materials for such vessels are metals which, if attacked, only yield salts naturally present in the human body, or metals quite immune from attack. He also referred to the way in which care of cleansing should govern the choice of forms, and to the possible future of magnesium alloys in household tools. He looked forward to a world in which good things are efficiently prepared and craftsmen take a worthy place, the right properties being selected for a given purpose, and incorporated in worthy design, in which human personality or individuality is not cramped or repressed. By utilizing in this way for all our purposes the new resources at our disposal and working in this spirit of evolution, we can build up the harmony of life which our civilization is missing.

The Position of the Jews

IN his pamphlet "The Jewish Question" (Oxford Pamphlets on World Affairs, No. 45. Oxford: Clarendon Press. 3*d*. net) Mr. J. Parkes points out that the Jewish problem arises from two sources: the Jewish tradition, which has inculcated in Jews the need to keep themselves separate if they would survive as Jews, and Jewish experience at the hands of the peoples among whom they have lived. Mr. Parkes shows how Jewry has been unfairly identified with all the malpractices of modern commerce and industry and the way in which prejudice, by embittering Jewish experience, has accentuated the minority problem which Jewry might normally present. Modern anti-Semitism has made the problem acute through two main factors: the persecutions in Tsarist Russia at the end of the nineteenth century, which led to the flooding of Western Europe and America with several million Jewish refugees from a totally different level of culture; and the fever of nationalism which spread over the world after the War of 1914–18 and made life difficult for all minorities.

Mr. Parkes considers that the accurate and scientific studies of the question we possess, and our knowledge of the effects of past experience, warrant the view that with planning and co-operation there is nothing in the Jewish problem which need cause pessimism or despair. He suggests that in the light of experience of the last twenty years, a minority is entitled to a communal organization, recognized as a public body, and with control over primary education and teachers' colleges, charitable foundations, and cultural activities, as well as to religious freedom and authority in religious matters where the minority is also a religious minority. On each point the majority has certain rights, for example, in regard to language. Among the Jews themselves, assimilation with their countries of adoption, or the foundation of a Jewish national home have been the main programmes proposed and followed. The basic problem confronting Jews lies in the view which they take of their status: whether they wish to be considered merely a religious minority or a separate national minority. The ultimate problem of Jewry is the rediscovery and reassertion of the fundamental spiritual and social realities of Judaism, to which both assimilation and Zionism are capable of offering soils already prepared.

Bread Flour

PROF. J. REILLY, professor of chemistry in the National University of Ireland (University College, Cork), has produced a booklet entitled "Our Daily Bread" which is particularly interesting at the present time in view of the desirability of making the British Isles less dependent on imports of wheat for its 'daily bread' (Cork: Forum Press. 2s.). He advocates the increased growing of rye, which is hardier than wheat and can be grown on poorer soils, and points out also that oaten and barley flour may without any dietetic disadvantage be used to eke out supplies of wheat. Growers of potatoes should be encouraged to set aside a portion of the crop for the production of potato flour, which is able to furnish us with our carbohydrate needs. It is interesting to note that flour was so scarce in England in 1800 that the Brown Bread Act was passed forbidding the use of pure white wheaten bread, and at this time flour was generally a mixture of equal parts of wheaten and rye flour. Wholemeal bread, of course, in contrast to white bread, contains comparatively large amounts of vitamins and minerals, although this is not the whole of the story.

Origin of Cultivated Water-Melons

ACCORDING to Dr. Orland E. White of the University of Virginia, Africa, not America, is the native land of the water-melon. Speaking before the meeting of the Virginia Academy of Science, he told of recent researches at the Blandy Experimental Farm, which throw new light on the ancestry of this plant. Water-melons were not known at either the Epicurean feasts of ancient Greece or the Lucullan banquets of Rome. Not until the great age of exploration in the sixteenth century do they appear in the world picture. Dr. White is of the opinion that the Portuguese, pushing southward along the coast of Africa, became acquainted with the ancestors of modern water-melons growing wild in South Africa. They soon transferred them to their colony of Brazil, where the Indians promptly adopted them and added them to their own array of crops. Thus the myth of an American origin of water-melons came into being.

Dr. White has obtained seeds of several strains of these small wild South African melons, which have little enough resemblance to the monsters of the modern melon patch. He also has under cultivation stocks of a bitter variety of melon, known as the colocynth, familiar to the ancient Egyptians and other Mediterranean peoples, but used by them only as medicine. He has made many crossings between them and modern cultivated water-melons, some of which may eventually prove commercially valuable.

Phenology of 1940

WITH commendable promptness, the fiftieth Phenological Report of the Royal Meteorological Society, covering 1940, has just been issued despite war-time difficulties making it impossible for the executive committee to meet since the last report. With the exception of a small amount of introductory text, the report consists of a series of tables and diagrams, as has been its increasing trend in recent years. It has the observations of 288 phenological observers in the British Isles, compared with 385 in 1939. The publication of full meteorological details is still restricted, but it includes the events of the historic cold spell early in 1940, probably the coldest January for a hundred years and the sunniest for fifty years. The marked lateness of plants and insects caused by the cold opening of the year gave place to considerable earliness which mainly persisted from the end of April, with a succession of warm, mild spells, and the beauty of spring and early summer was enhanced by the simultaneous occurrence of normally early species which had been retarded and the normally later species which were brought forward.

This recovery also applied to crops, although some autumn-sown cereals failed to survive the winter. The droughty conditions in May, June, and, after a cool showery July, again in August and early September, had an interesting effect upon the grass; in the north-west the assessed condition remained between 77 and 78 per cent throughout August, whereas in the south-east it deteriorated from about 77 per cent to about 56 per cent, during which period the rainfall was about 30 per cent of the average in the north-west but only 3 per cent in the south-east. Indigenous insects are unlikely to have been affected so much as indigenous birds, which, however, had a favourable nesting season after so hard a winter. Migrants arrived at dates not far from average in the south but somewhat later in the north, while the only large-scale insect immigration was that of the large white butterfly (*Pieris brassicæ*). The comparative earliness of the north-west district is shown in the plant and insect diagrams, in advance of the south-east up to May.

Design of Wire Networks Carrying Radio Programmes

IN the *Bell Laboratories Record* of April there is an instructive paper by A. E. Bachelet explaining some of the difficulties encountered when designing wire networks over which radio programmes are transmitted. These in America often form extensive systems with broadcast stations or studios in most of the larger systems interconnected by high-quality circuits employing amplifiers. The transmission over these circuits differs from ordinary telephone transmission in that it is unidirectional, and one-way amplifiers are employed. Since a studio may either transmit or receive programmes, it is necessary to provide means for changing the direction of transmission over the network. In the past this has been done either by using separate facilities which transmit in opposite directions, or by interchanging the input and the output of the amplifiers by the use of switches manually operated.

To provide quicker reversals, a remotely controlled reversing circuit has been developed which permits the reversal of the circuits to be controlled from the studio originating the programme. Reversals are effected by relays, controlled by direct current transmitted over the two conductors of the programme circuit, and returned through the earth. Any studio may assume control and set up the network so as to transmit the programme from it to the other points on the network. As long as this studio retains control, no other studio can alter the conditions. The reversing equipment is required at every amplifier point, which may be a simple amplifier station along the line, or a main junction or terminal connecting to a broadcast studio.

Swiss Electrotechnical Industry during War-time

IN the February issue of *Swiss Technics*, a journal published by the Swiss Office for the Development of Trade (Zurich and Lausanne), which co-operates with the Swiss Association of Machinery Manufacturers, Zurich, there is an instructive account of a visit made to the Secheron Works at Geneva. These works have always been strictly limited to the construction of heavy electrical machinery and material. A few years ago, when the electrification of the chief Swiss railroads, to which the Secheron Works greatly contributed, drew to a close, new lines of manufacture were taken up. Among these was the building of electric welding apparatus and the manufacture of the necessary electrodes. The Secheron alternating-current arc-welding apparatus has now almost everywhere replaced direct-current revolving units. For the welding of complicated parts 'exotherme' electrodes are almost universally employed; cut-out or stamped parts can be simply welded together by the melting of the electrode into the space left between them, thus forming a solid block as homogeneous as a foundry casting.

Enormous alternators for the hydro-electric power station of Verbois are now being constructed at the works. These machines resemble two-storied towers, 9·2 metres high and each weighing 300 tons. All parts are electrically welded and every welding has been carefully inspected by radiograph. At normal speed the peripheral speed of the polar wheel will be equal to 155 km. per hour; at 300 rev. per min. this speed attains 350 km. per hour. A 3,000-h.p. motor is being built for Norway and twelve transformers of 1,000, 2,000 and 3,200 kva. are being built for Ireland.

Electro-formed Reflectors

THE construction recently of 62-in. searchlight reflectors at the Bart Laboratories, New Jersey, shows, according to the *Electrical Review* of April 11, that satisfactory progress is being made in modern electro-forming methods. An electro-formed nickel-surfaced mould is first of all made and a coat of nickel 0·003–0·005 in. thick is applied to the outer passivated nickel face. Then follows a coating of copper, to which a pre-formed bronze ring is applied, and the assembly is given a heavy deposit of copper. These firmly bonded layers are stripped from the mould in the form of a bi-metal reflector with copper on the convex face and nickel on the inner polished face. To prevent the introduction of copper into the rhodium bath, a protective mask is fitted on the copper side. The reflector is now ready to receive its rhodium-plating, and in this instance a 'flash' of rhodium 30 millionths of an inch thick appears satisfactory.

The advantage of this method appears to be in the use of rhodium on a nickel base. It has a high hardness (about 600 Brinell), is tightly adherent to its underlying layer, and also has a high degree of reflectivity and resistance to tarnish. The coatings of rhodium used are exceptionally thin; but as nickel is passive when plated with rhodium, adequate protection is provided. It is stated that full protection is lacking with underlayers of copper and its alloys, the relation of which to rhodium in electro-chemical action is such that disfigurement by corrosion may result.

Japan Institute for the Science of Labour

THE annual report of the Director of the Japan Institute for the Science of Labour for 1939, recently received, in reviewing the present activities of the Institute, emphasizes its objectives in assisting the development of the national industrial capacity, including the training of workers, as well as the improvement of working conditions, and the stimulation of leadership. Reference is made to the investigation of industrial hazards as well as of the problems of agricultural workers, including their maintenance. A somewhat naïve claim is made for the uniqueness of the Institute, as well as a reference to its part in the establishment of a 'New Order' in the Orient. The report also includes the director's address on the "Function and Guiding Spirit of the Institute", given at its first staff conference, in which the character of the Institute as a purely scientific research body covering the daily life of the industrial and agricultural worker is emphasized, and also the importance of its contribution to national productivity and culture. Stress is laid upon the team spirit in the research work of the Institute and its service of social and national needs. Details of the various research sections and laboratories of the Institute are given, as well as of projects already under investigation.

Thin Glass for Microscope Cover-Slips

THE year 1940 marked the centenary of the manufacture in Great Britain of specially thin glass for microscope cover-slips. Prior to this date, it was customary for microscopists to use thin talc or mica for covering specimens to be examined under the microscope. This manufacture was started by Messrs. Chance Brothers and Co., Ltd., at Smethwick, in 1840 as nearly as is known, and has been carried on continuously by the same firm up to the present day. The War has called for a considerable increase in supplies of such glass, both in Great Britain and abroad. There was no essential change in this type of glass until about 1928, when a research was carried out on the development of microscope cover-slips. It was found that the old type of glass, which was essentially like window glass, would not withstand tropical conditions without becoming clouded. Therefore, new methods of manufacturing a glass which would withstand sterilizing and exposure to tropical atmospheres without any deterioration were introduced. The thickness of cover-slip glass is still classified under the headings: Extra thin (0·075–0·100 mm.), No. 1 (0·100–0·167 mm.), No. 2 (0·167–

0·215 mm.), and No. 3 (0·215–0·300 mm.). These correspond closely with the figures quoted in a catalogue issued by the firm in March 1859, which says No. 1 is 1/250 in. in thickness, No. 2 1/160 in., and No. 3 about 1/100 in.

Vital Statistics in Queensland

Out of a total of 9,530 deaths in Queensland in 1939, 2,786 were classified as due to diseases of the heart or circulatory system. Cancer and other tumours were responsible for 1,069, and diseases of the respiratory system for 811. Parasitic and infectious diseases claimed a total of 747, the chief of these being pulmonary tuberculosis (290) and influenza (221). Violent or accidental deaths claimed 812 victims. Out of a mean population of 1,013,000, more than 95,000 received treatment at public hospitals during the year.

Earthquakes Registered at Kew

Between May 18 and June 15, seven large earthquakes were registered by the seismographs at Kew Observatory. These were on May 23 (two), 24 and 30, June 6, 10 and 11. The two shocks on May 23 were from the same epicentre 2,850 km. distant. They commenced with compressional waves at 19h. 57m. 17s. and 22h. 39m. 33s. G.M.T. respectively, and the first attained a maximum ground amplitude at Kew of 24 μ. The shock of May 30 at 21h. 47m. 32s. G.M.T. from 17,000 km. may have had a focal depth of about 400 km. and the shock of June 10 at 20h. 46m. 10s. G.M.T. from 4,900 km. may also have had a deep focus (450 km.). The other shocks were smaller, and all the readings and calculations are tentative.

Earthquake in Baja, California

The United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, on the basis of reports from fourteen seismograph stations, has found the epicentre of the earthquake of March 15, 1941, at 5h. 46·3m. G.M.T. to be provisionally at latitude 28·1° N., longitude 113·6° W. This is south-west of Calmalli and towards the northern end of the Vizcaino Desert, in an established seismic region.

Wilhelm Preyer (1841–1897)

Prof. Wilhelm Thierry Preyer, a well-known German biochemist and psychologist, was born on July 4, 1841, at Moss Side, Manchester. He studied in Bonn, Heidelberg, Berlin, Vienna and Paris, where he was a pupil of Claude Bernard and Wurtz. In 1869 he was appointed professor of physiology at Jena, where he remained until 1888. He then moved to Berlin, where he served as lecturer until 1893 when he retired, and died at Wiesbaden on July 15, 1897.

Preyer was a prolific writer, first in biochemistry and later in psychology. His biochemical publications were concerned with hæmoglobin and methhæmoglobin (1868), blood acids (1868–70), blood crystals (1871), while his psychological works included the five senses of mankind (1870), the causes of sleep (1877), colour and temperature sense (1881), discovery of hypnotism (1881), and the soul of the child, which went through eight editions (1882–1912).

The Night Sky in July

The moon is full on July 8 at 20·3h. and new on July 24 at 7·7h.U.T. The bright star, Aldebaran (magnitude 1·1), is occulted by the moon on July 20. As seen from Greenwich the predicted time of disappearance is 2h. 47·0m. U.T. at position angle 38° from the north point of the moon's image; the reappearance is at 3h. 34·0m. at position angle 297°. (sunrise is at 4h. 5m.: add 2h. to all times to convert to Midsummer Time). Of the planets visible during this month, Venus is low in the west after sunset and not easily seen. Mars is above the eastern horizon at about 23½h. in mid-July. The gibbous phase of its disk can be seen in a small telescope. The planet is increasing in brightness. Saturn and Jupiter are both morning stars. Saturn is in conjunction with the moon on July 19d. 1h. and Jupiter on July 20d. 9h. After the middle of the month, Mercury may be seen as a morning star, greatest elongation (20° west) occurring on July 24.

Announcements

Sir Henry Dale has announced in a letter in *The Times* the gift by the American Physiological Society of 5,000 dollars to the Royal Society "for the support of British scientific publications, especially in physiology". This is the third gift recently made by American scientific institutions to aid science in Britain; the Rockefeller Institution made a grant for publications (Nature, Feb. 22, p. 237) and the American Philosophical Society has given 10,000 dollars "for the aid of science in Britain" (Nature, April 5, p. 414).

Prof. Frank Horton, professor of physics in the University of London, has been re-elected vice-chancellor of the University for the year 1941–42.

Dr. R. J. W. Le Fevre, lecturer in chemistry at University College, has been appointed reader in the University in respect of that post.

The following doctorates have been conferred: *D.Sc.* on Mr. Bruce Chalmers, of University College, and on Mr. S. G. Clarke, of Battersea Polytechnic; *D.Sc.* (*Economics*) on Mr. S. K. Muranjan, of the London School of Economics.

An Academy of Sciences has been established at Tiflis, Georgia, in connexion with the University.

The Trustees of the Lady Tata Memorial Fund announce that, on the recommendation of the Scientific Advisory Committee, they have agreed, if circumstances permit, to make the following awards for research in blood diseases, with special reference to leukæmia, in the academic year beginning on October 1: Grants for research expenses to Dr. J. Furth (New York), Dr. P. A. Gorer (London) and Dr. A. H. T. Robb-Smith (Oxford); part-time personal grant and grant for research expenses to Dr. W. Jacobson (Cambridge).

Quantum Theory of X-Ray Reflexion

In a memoir which appeared in 1926, Laue[1] showed by purely classical reasoning that the X-rays scattered by elastic solid waves of thermal origin in a crystal have the frequency $\nu \pm \nu^*$, ν being the primary X-ray frequency and ν^* the frequency of the elastic waves. He evaluated I_ν and $I_{\nu \pm \nu^*}$, these being respectively the intensities of the reflexion and the scattering by any assigned set of lattice planes in the crystal. The value of $I_{\nu \pm \nu^*}$ for any specified direction of scattering may be found by assigning the appropriate wavelength and orientation to the elastic waves in Laue's formula. The ratio $I_\nu / I_{\nu \pm \nu^*}$ comes out, as might naturally be expected, to be of the order N, this being the total number of atoms in the irradiated solid. Even for a tiny crystal only 1μ in size, the ratio is thus of the order 10^{11}. In other words, the scattering in any specified direction by the lattice planes has an intensity wholly negligible in comparison with that of the coherent reflexion by the same planes.

In an article published in *Current Science* of April 1940, and in a series of three papers following it in the *Proceedings of the Indian Academy of Sciences* for May 1940, experimental evidence was presented showing that the lattice planes in a crystal are capable of giving a second kind of specular reflexion which differs from the reflexions of the classical type in being of a dynamic character and having an altered frequency, besides obeying different geometric laws. Experimental evidence was also presented showing that these reflexions are due to the excitation of the *optical* vibrations of the crystal lattice, and reasons were given for the view that this new type of reflexion is a quantum-mechanical effect.

Other alternative theories of the phenomenon have appeared which, in our view, are neither in accord with accepted physical principles nor with the experimental facts emerging from our investigations. We may, in particular, refer to a view which has been repeatedly expressed[2,3], namely, that the effects observed are diffuse maxima in the scattering of X-rays by elastic waves of thermal origin. This suggestion is, in our opinion, completely contradicted by the observed intensity of the reflexions and their persistence over a large range of settings of the crystal. As shown by our investigations, the intensity ratio between the unmodified and modified reflexions of monochromatic X-rays varies greatly with the crystal, its setting and with the spacing studied; it is generally of the order 1000 : 1, but certainly nothing like 10^{11}. The actual facts of the case can only be understood on the view that we are dealing with the optical vibrations of the crystal lattice; these produce large dynamic variations of the structure amplitudes and negligible distortions of the lattice, unlike the elastic waves, in respect of which the situation is exactly the opposite.

As is well understood at the present time, classical optics and quantum mechanics are mutually complementary and not contradictory. Classical optics indicates that a crystal in which the interpenetrating lattices vibrate with reference to each other would give intense specular reflexions of X-rays with an altered frequency. When, therefore, such an effect is actually observed, it is a legitimate inference that the changes in the energy level of the crystal associated with such a reflexion are to be regarded as induced by the incident radiation itself; in other words, that the intensity of the reflexions is determined by quantum dynamics and not by the classical mechanics. This view led us to predict[4] that the intensity of the modified reflexions by the $\{111\}$ planes of diamond would remain unaffected by cooling the crystal down to liquid air temperatures. This prediction has been completely confirmed by our experiments[5]. Neither the high elasticity of diamond nor the existence of a zero-point energy appear to us to be in any way relevant as an explanation of the observed facts[6].

The Lightning and Spark Discharges

It has recently been pointed out[1] that though the charge leaving the cloud in a lightning flash to earth is probably about half as great again as had hitherto been believed, the potential of the thundercloud base is probably only a few per cent of previous estimates[2]. It already appears[1] that the condition for the occurrence of a flash is not that the breakdown potential be attained over the whole intervening space[2,3], but that a concentration of field should occur of sufficient intensity to initiate what may be called a 'self-propagating' discharge in a field which elsewhere may only reach a few hundred volts per cm. The implications of this are so important in the theory of discharges in general that further confirmation is very desirable. The purpose of this note is to suggest a mechanism to account for the 'darts' of the first leader stroke and the low overall voltage, to direct attention to a characteristic of such discharges which has hitherto been overlooked, and to suggest the condition under which spark breakdown occurs.

One characteristic of the first leader stroke which is nearly always observed is its discontinuous or 'dart'-like appearance[4], which in my opinion has not so far been satisfactorily accounted for. The explanation now proposed is that the *'darts' represent the sudden transition of newly formed portions of the* *advancing streamer from glow to arc conditions.* As the streamer advances, an increasing current must flow through the tip of the preceding dart to maintain the increasing lateral or corona current from the sides of the streamer. When this current, together with the small current involved in the vertical progression of the tip, builds up to the order of one or a few amperes, sudden transition from glow to arc will occur[5,6,7]. The order of magnitude at least of the current attained when the streamer reaches a length of 7–10 metres, and the average length of the darts, can be estimated from the charge neutralized in the atmosphere by the average lightning flash, namely, about 10 coulombs, of which about half is probably neutralized during the first leader stroke[1]. From the duration of the leader stroke, say 10^{-2} sec., and the length of the lightning channel, say 2·5 km., this neutralization requires a lateral current of the order of 4×10^{-3} amp. per cm. length of channel, or 3–4 amp. over the length of a dart. Allowance for the branching of the first stroke would merely reduce this current by a factor of about 3, so that this current is in good agreement with that for which glow - arc transition occurs.

Further support is derived from a consideration of the transition from arc back to glow. This occurs for a current which is about 10 per cent of that required for glow - arc transition[7], so that arc conditions would not be maintained in the last tenth of the dart length, which would therefore be re-illuminated by the succeeding dart, just as has been actually observed by Schonland[4]. Again, Allibone and Meek[8] observed that currents of the same order flowed during the leader stroke of the spark discharge, and it is interesting to observe that, owing to their rapidly varying nature, the currents in the leader strokes in this case were often greater than those of the subsequent return strokes, a conclusion supported by the relative photographic intensities of the two strokes.

Such an arc channel can be regarded simply as an extension of the initiating conductor, and the voltage gradient along it is only of the order of 10 volts per cm. These considerations explain the 'self-propagating' nature of the discharge and the large charge neutralized by the corona, which is thus seen to be an important, though hitherto unrecognized, feature of the discharge.

The condition for the occurrence of a spark in a non-homogeneous field would thus appear to be that *the current in the brush discharge from an electrode should be sufficient to cause glow - arc transition to occur*, after which the leader progresses by the above mechanism.

A more detailed account of this work will be published shortly.

An Effect of Light in Gases under Electrical Discharge

THE observation reported previously[1], namely, an instantaneous diminution of the discharge current in chlorine on irradiation, has now been extended to other gases subjected to ionization by collision in electric fields due to alternating potentials in Siemens' tubes.

It is observed that the photo-variation of the discharge current varies rapidly in the order: chlorine, bromine, hydrochloric acid gas, iodine. In fact, observation of the effect in iodine is nearly impossible without a sensitive indicator and adequate irradiation. Furthermore, especially in the case of iodine, the photo-effect is easily masked by a dark, in part, 'ageing' effect, that is, a time-variation of the discharge current produced under a constant applied potential; this varies in the order: iodine, bromine, chlorine. Other conditions remaining the same, a rise in the gas pressure and temperature tends to diminish the light-effect; an increase in the applied potential, frequency of the A.C. supply and of the external radiation employed, as also its intensity, increases it.

Preliminary experiments have shown that differences in the magnitude of the light-effect in chlorine using plane polarized and equally intense ordinary light lie within the margin of probable experimental error.

The use of larger discharge tubes, radiation of much greater intensity and of shorter wave-length, and of specially sensitive current indicators has revealed the effect in oxygen, air, nitrogen and hydrogen; its magnitude is, however, very considerably smaller in these gases than in the case of the halogens.

Pigmentary Changes and the Background Response in Amphibia

THE results of recent experiments of mine have shown that our conception of the nature of the background response in Amphibia is inadequate and must be extended. When *Rana temporaria* is kept on an illuminated black background for several weeks, melanin granules are dispersed in the melanophores and the amount of melanin in the skin is increased. Conversely, when the animal is kept on a white background, melanin granules are aggregated in the pigment cells and the amount of melanin in the skin is decreased. In short, additive and subtractive processes are operative. Both effects have been observed by means of photometric determinations of solutions of melanin extracted from the skin, and the latter effect is apparent microscopically in the degeneration of melanophores[1].

Other experiments of mine have tended to show that the amount of melanin in the retinal pigment epithelium of *Rana temporaria* varies under certain conditions. When the eye has received the radiations from a Hanovia lamp, melanin granules may be densely aggregated at the same time in both the basal regions and the processes of the retinal pigment cells. A condition thus arises which is not ogical and which combines the pigmentary ers of both the dark- and the light-adapted or this and other reasons, the idea of pigment on in the retina has been criticized and it has uggested that whether or not actual movement nules occurs as a result of cytoplasmic streaming as has been postulated, other processes are bably at work. One possibility is the concomitant aching or destruction of pigment and colour ensification or the development of pigment in fferent parts of the pigment cells[2].

Since my papers went to press, I have discovered the literature facts which have some bearing on y work and which deserve brief comment. Figge[3] epeated the experiments of Lewis[4] on the development of pallor in the larvæ of amphibians reared in solutions of dyes which are also oxidation-reduction indicators. Pallor seemed to imply the destruction of melanin, but was found to arise in consequence of the inhibition of tyrosinase action by the dye[5]. Tyrosinase is regulated by oxidation-reduction potenials, and in a mixture of melanin with redox inditors, sodium hydrosulphite not only decolorizes the e but also alters black melanin to a light brown lour. The subsequent addition of potassium ferrianide to the mixture reverses the change and tores to the pigment its former black colour. ge concluded that melanin is a natural reversible idation-reduction system.[6]

Natural melanin, like the pigment produced by oxidation of dihydroxyphenylalanine (dopa), is pable of reversible oxidation and reduction, but e reaction is far more sluggish and barely pereptible, perhaps because of the low concentrations used in the tests and of contaminants in the reaction mixture. The pure melanin which occurs in the ink of the squid *Loligo pealii* was found to be almost as reactive as dopa melanin and capable likewise of alternate oxidation and reduction repeatedly with corresponding colour change and without significant final loss of colour[7].

These facts suggest that the pallor which is due to the white background response may involve alteration rather than actual degradation of melanin. If such pallor is due to the inhibition of tyrosinase action, however, the loss of melanin can be explained on the assumption that under conditions of neutral background the pigment is being both produced and excreted or otherwise lost continually, and that under conditions of white background melanogenesis is suspended while the excretion of melanin continues. Some pigment must be lost at all times and under all conditions by moulting of the epidermis, and unpublished observations of mine show that more is lost by this means in dark than in pale animals. From this it seems likely that under conditions of black background melanogenesis is heightened even more considerably than the experimental data in my earlier paper suggest.

If apparent loss of melanin under conditions of white background is due even in part to discharge of the black colour by alteration of melanin, the observations of Figge suggest that the cause is to be sought in oxidation-reduction processes of pigmented tissues. Such a possibility was in fact in my mind when I made the suggestion of bleaching and darkenng processes as an alternative to the idea of pigment migration in the retinal pigment epithelium. It now ems likely also in regard to the skin and other es in which melanin is to be found.

A further possibility presents itself, namely, the interaction of melanin and/or its precursors (at least two of which are capable of reversible oxidation and reduction) with other systems of similar nature, notably lyochromes but also carotenoids. It seems significant that lactoflavin is accumulated in the pigment epithelium of the perch retina[8], and that in non-scaly fishes like the eel the melanophores of the skin have a high flavin content[9]. If melanin and its precursors are functionally related to such important systems as the flavoproteins and carotenoids, pigmentary changes in the skin and the retina acquire physiological significance and the occurrence of melanophores in the walls of blood capillaries, the membranes of central nervous organs, and the other deep situations in which they seem incongruous is less enigmatical.

"Vegetables as Food"

Drs. Booth, Mapson and Moore[1] feel that in a recent article in Nature[2] I exaggerated when I made "an allusion, divorced from its context, to cooked cabbage as having only 17 per cent of the vitamin C of the fresh cabbage". What I wrote was as follows. "A cabbage bought at the market may perhaps be expected to contain 60 per cent of its original vitamin C content, the housewife probably throws away no more than 20 per cent of the remainder in preparing the vegetable for the pot, leaving 40 per cent [more correctly 48 per cent] of the original vitamin. During boiling, however, . . . about 65 per cent is extracted by the cooking water and usually thrown away. Thus 17 per cent of the vitamin C with which the cabbage left the field is all that remains when it reaches the table."

I still believe this statement to be substantially true. When the urban housewife buys her cabbage it may be some days old, and loss of freshness carries with it loss of vitamin C. After she has bought it, part at least may be stored for a further period in her larder or kitchen, where further loss occurs. Miss Olliver, in an address of which my article was in part a review, showed that only 37 per cent of the original vitamin C may remain in shop-purchased cabbage, although, as she also shows, there may in better circumstances be no loss at all. I do not therefore feel that my figure of 60 per cent is unfair. My next figure of 20 per cent loss in preparing the vegetable for the pot is admittedly an estimate, but bearing in mind that the heavy outside leaves which are discarded are richest in vitamin C, I hoped it was not unreasonable. The losses of the remaining vitamin during boiling shown in Miss Olliver's tables which she had kindly made available to me were as follows:

Cabbage: 62, 62, 61, 69*, 66, 53, 66 per cent.
Kale: 67, 46, 77*, 76*, 78*, 71*, 84 per cent.

* Probably normal method of cooking.

I am aware that losses of the order of 40–50 per cent can be achieved, and in agreement with the Cambridge workers I myself have obtained figures as low as 20 per cent. The bulk of the evidence seems to show, however, that, in general, losses of vitamin C are very high.

Dr. Booth and his colleagues will receive the thanks of all workers in nutrition for their figures for carotene in carrots. Anyone who has occasion to use published tables of carotene values knows the bewilderment of choosing from a confusion of figures often differing many fold. But while the position of vegetables as sources of carotene and hence of vitamin A available to the body has not yet been completely elucidated, the standing of green vegetables as a source of vitamin C is beyond dispute. As Miss Olliver and Mr. Adam truly state[3] they "can adequately supply the full daily requirement of the vitamin". This they do, I cannot help believing, only after the bulk of the vitamin supplied by bountiful Nature has been lost. Can we afford to lose so much in present times ?

[2] Pyke, M., NATURE, **147**, 513 (1941).

[3] NATURE, **147**, 711 (1941).

Whilst it is an accepted fact that there may be considerable wastage of vitamin C when vegetables are cooked, any statement which tends to underestimate the antiscorbutic value of cooked vegetables is to be deprecated.

Dr. Pyke's original article tends to give this impression, and it is unfortunate that such an impression should be confirmed by the choice in the above letter of figures separated from their context.

M. OLLIVER.

Science and Society

HITHERTO most apologists for science have done little more than stress the potential value of aspects of technology, such as would provide new foods, weapons and other *things*. Until recently this was the only non-cultural justification of science, but to maintain it now is out of date.

Our society may be likened to a badly run office, the directors of which are ready to call in a tradesman to stop a leak obvious to the senses, but have no idea of using intelligence and skill of another order to put a stop to ineffective methods in the running of the office itself. Let not men of science put themselves in the position of forming only a works and repairs department of the office, with no concern except to press for more and better plumbing, or to suggest that it need not be confined to repairs.

The politician, a victim of his education, is unaware of common scientific concepts such as limiting values and the elementary theory of errors. It appears that his notions of equilibria are represented by arithmetical averages in a static two-phase system, and that he can conceive of no interactions more complex than those of a game of chess—in which one piece is moved at a time. The chances are even that subjective decisions will be wrong ; nor is any test of their validity possible.

As a result of work in the field of mathematical statistics, our generation is the first to have the power of applying objective tests to many social problems. To this ability is added the pra
of assessing the validity of the results.
thought applied to such matters as the
and evacuation could have avoided their
and lessened the harm done to our nationa
Unfortunately, it was not officially realized th
problems were amenable to objective methods.

The new discipline has been developed prim
in Britain and secondarily in the United States.

Infestation of Manufactured Food by Insects

DR. D. N. ROY's letter in NATURE of Jun
p. 746, suggests that the special problem to
he refers is something apart from the problems
I described in my report to the Departme
Scientific and Industrial Research. In fact, it is
kind of problem to which I directed attention.

Some years ago, considerable time and stud
given in my department to the cause of infest
of a manufactured commodity similar to, if
identical with, that referred to by Dr. Roy.
conclusion reached was that as precautions had
taken to ensure bottling of the commodity
sterile conditions the method of sealing was at fa
In the course of the investigation, evidence wa
obtained that infestation might occur at almost any point in the marketing of the commodity, and that a most likely point or focus of infestation was the Indian go-downs in which, according to reports
received, the beetles Silvanus and Tribolium wer
abundant.

"Plankton as a Source of Food"

THERE is one point which I should like to add to Prof. Hardy's article on "Plankton as a Source of Food"[1]. He is concerned chiefly, and rightly so, with marine plankton. Would it not be possible to make use also of the freshwater plankton from our lakes and reservoirs ? In this connexion I may refer to
statement by (the late) C. H. H. Harold[2], that a certain reservoir was estimated to contain 10,80
tons (wet weight) of algæ ; and even allowing tha
that estimate is somewhat of an exaggeration, a
appreciable quantity must have been present, for h
goes on to say that 90 tons were removed daily b
filtration. More recently, Gardiner[3] speaks of
reservoir having, at the spring maximum, a crop
Fragilaria crotonensis estimated at a dry weight
110 tons. It would seem, therefore, that here,
least, is ample material for investigation.

RESEARCH ITEMS

n of Sex Chromosomes

J. D. WHITE (*J. Gen.*, **42**, 143–172 and 173–190 ; .) has examined the sex-chromosome mechanisms raying mantids and in the crickets and grass- ors. The majority of the Mantoidea have an *XX* sex chromosome mechanism ; the *X*- posome is mediocentric. In the sub-family tiniæ *sensu stricto* a $X_1X_2Y_1 : X_1X_1X_2X_2$ mech- m has been developed. The author shows that probably arose from the *XO* type by a mutual translocation between the *X* and an autosome. The sizes of the component chromosomes may differ as the result of succeeding translocations. Meiosis ppears to be of an anomalous type, and it would eem impossible to determine by cytological methods her crossing-over occurs, since chiasmata are not . It is shown that translocation simultaneously ving both *X* and autosomes in the Tettigondæ s rarely if at all. The *X* is therefore in evolu- ry isolation. Therefore differences in sizes and e of the *X*-chromosomes of neighbouring genera arisen from internal rearrangements. These ngements may be beneficial in readjusting balance, upon which sex determination depends.

n of Cherries

RAPTOPOULOS (*J. Gen.*, **42**, 91–113 ; 1941) has ined the cytological behaviour of Duke, sour d sweet cherries and several hybrids. He shows hat the Duke cherries and the sour cherries are autotetraploids, but of different origins. The Duke herry probably is a tetraploid derivative of *Prunus vium*, whereas the sour cherries probably arose om a species cognate to *Prunus avium* which ered in a number of genetic characters. The ntitative data on which the above conclusions based are that the Duke cherries have a high sma frequency (1·59) while the sour cherries ave a lower frequency (1·34). When crossed together, the sour cherries are able to produce as many quadrivalent configurations as in the Dukes themselves. Hence selection has taken place in the sour cherry for low chiasma frequency. There is an nverse ratio between fertility and number of quadrivalents in nine species and varieties of tetraploid herries.

ltra-Violet Absorption by *Drosophila melanogaster*

SINCE ultra-violet radiation gives rise to lethal gene utations in Drosophila, it is important to know how uch radiation penetrates the body cells before aching the sperms. As a first approximation, Durand, A. Hollaender and M. B. Houlahon . *Hered.*, **32**, 5'–56 ; 1941) have observed the sorption of radiation by the abdominal wall tween 2140 A. and 4400 A. under an ultra-violet croscope. It was found that the abdominal wall unexpectedly transparent. Below 3000 A. there is rapid increase in absorption ; this ranges from ut 20 per cent at 4400 A. to about 94 per cent at A. It is necessary, therefore, to know the nt of absorption in the overlying tissue in to know the dose which induces gene mutation testis.

Wing Development in Drosophila

MANY genes affect the characters of *Drosophila melanogaster*, and, as shown by Waddington, these affect the wing at different stages of development. A. D. Lees (*J. Gen.*, **42**, 115–142 ; 1941) has wounded the developing wing of pupæ 0–3½ hours old, 4-6 hours old and 6–21 hours old. Wounding the wings of the youngest pupæ gave rise to tilt, fused, vesiculation and scalloping effects. Wounding of the 4-hour-old pupæ gives characteristic rounded wings due to an inhibition of cell multiplication and to the dumpy effect. Injury of the older pupæ leads to holes in the epithelium, to production of extra veins as in Delta, and alteration of the position of the posterior cross vein. These experiments shed considerable light on the means by which one gene may affect a final character expression by disturbance of the normal development at a particular stage.

Behaviour of Nitrogen and Hydrogen on Osmium

HABER in his classical researches on the synthesis of ammonia found that osmium was an excellent catalyst. The catalysts for this important synthesis have commanded much attention. Recently H. S. Taylor and Joris have investigated the exchange of nitrogen isotopes on a promoted iron catalyst, and they have now extended their studies to an unpromoted, metallic osmium catalyst (*J. Chem. Physics*, **9**, 287 ; 1941), prepared by the decomposition-reduction of ammonium osmium chloride in a stream of hydrogen at 300° C. Activated adsorption of hydrogen on osmium occurs between 80° and 573° K., but at low temperatures a certain amount of van der Waals' adsorption is also evident. With nitrogen, throughout the same temperature range, van der Waals' adsorption decreases as the temperature is increased. The isobar at 1 atmosphere shows a minimum at 350° and then increases, due to activated adsorption, to a maximum at 428°. The nitrogen adsorption is less than 10 per cent of the hydrogen adsorption at one atmosphere between 273° and 573°. At 473° the isotopic exchange of nitrogen, $^{28}N_2 + {}^{30}N_2 = 2\,{}^{29}N_2$, is just measurable, but at 573° it is very rapid and has an activation energy of 21·8 kgm.cal. The reaction is inhibited by hydrogen and becomes unmeasurable when the hydrogen content exceeds 50 per cent. Ammonia decomposes six times as fast as the rate of the exchange reaction and yields a 1 : 3 nitrogen-hydrogen mixture. The mechanism of the exchange appears to be controlled by the migration of atomically bound nitrogen on a surface on which active centres are few. The area per gram of osmium has been calculated as 30·8 square metres, but only 4 per cent of this area is covered by nitrogen at the temperature of maximum activated adsorption (428°).

Optically Active Dyes

THE present view of the mechanism of the dyeing of textile fibres is that it occurs in three stages : (1) diffusion of the dye into the submicroscopic voids of the fibre, (2) adsorption of the dye, (3) irreversible fixation of the dye. The nature of the union between the dye molecule and fibre molecule is not established, but it is generally supposed to be a physical adsorptive phenomenon occurring through hydrogen bonds and secondary valencies in the dyeing of vegetable fibres, and chemical phenomena such as salt formation in the dyeing of animal fibres. But the distinction between these two types of combination is not sharp, and the process might be the result of both. Some slight evidence of optically selective adsorption of one form of a dye containing an asymmetric carbon atom, claimed by Morgan and Skinner in 1925, has not been substantiated, so that the partial resolution of a dye in the racemic form in associating with the optically active structure of protein and cellulose fibres, which would favour a chemical combination, is not proved. W. R. Brode and R. E. Brooks (*J. Amer. Chem. Soc.*, **63**, 923; 1941) have now synthesized a dye in which the whole molecule, and not merely a carbon atom well removed from the origin of colour, is asymmetric, and the chromophore and auxochrome groups are situated as nearly as possible to the seat of optical activity. It was prepared by tetrazotization of the active and racemic forms of 2, 2′-diamino-1, 1′- dinaphythyl and coupling with phenyl-*J*-acid. Dyeing tests with these active and racemic dyes failed to show any selective absorption by wool or rayon fibres, and support a physical, rather than a chemical, combination between fibre and dyestuff.

Vapour Density of Iodine

AT ordinary temperatures, iodine consists of diatomic molecules. At 600° dissociation is less than 1 per cent, but at 1200° it is 50 per cent. The equilibrium $I_2 \rightleftarrows 2I$ has been previously investigated several times, but there is a lack of concordance among the data. A re-examination has been made by G. K. Rollefson and Perlman (*J. Chem. Physics*, **9**, 362; 1941) in order to obtain reliable data and to test experimentally if existing difficulties arise from the presence of triatomic molecules, which, on theoretical grounds, are considered sufficiently stable to exist in the vapour state (*J. Amer. Chem. Soc.*, **54**, 170; 1932). The pressure – volume products of iodine vapour were measured between 723° and 1274° K. In this region iodine vapour contains no trace of triatomic molecules, but is an equilibrium mixture of I_2 and I. From equilibrium constants and known energy levels of I_2 and I, the heat of dissociation of iodine is 35,514 ± 50 gm.cal., in close agreement with the value obtained directly from spectroscopic data.

Design of Joint Boxes for Super-Tension Cables

C. E. ROSE has published a useful practical paper on the design of a joint for splicing together consecutive cable-lengths or for connecting up cables to station switchgear (*Eng. Supp., Siemens Mag.*, No. 292, 1941). One of the main causes of trouble results from the expansion caused by the temperature effects of the load. The expansion of insulating compound used in joints is of the order of about 3 per cent over the usual working temperature range. Cable oil expands to an even greater extent when the conductors are carrying heavy loads, exerting pressure on the lead sheaths and sealing ends, and so tends to penetrate the joint boxes. When solid compounds are used for filling the joints and end boxes, up to 11 kilovolt working voltage, a high melting-point solid-setting compound of bituminous nature is usually employed. This tends to act as a bar
to the flow of cable oil. Provision has to be ma
the end boxes for the expansion of this compo
and also for the seeping of the cable oil, which
soften the solid compound in places where they c
into contact. For voltages greater than 11 kilov
a compound of a semi-fluid nature with a si
constitution to that of the cable impregnating
used for filling joint sleeves and end boxes. E
all boxes used for these compounds must be per
oil-tight. Where steep gradients occur in the
route, it may be advisable to stop the interch
of compound between the cable and the joint
to isolate each length of cable on a slope. This
limit the pressure set up at the lower end of e
cable length, and prevent undue draining of the ca
oil. These joints are known as barrier joints
virtually comprise a double-end box, each c
terminating on either side of the barrier plate.

Limits of Uniform Galactic Absorption

THE results of investigations on the questio
general galactic absorption have been rather
cordant. This is partly due to the recogn
irregular distribution of the absorbing matter, pa
to the uncertainty about the distances of the s
and partly to the non-homogeneous working mat
which includes early stars, late stars, Cepheids,
clusters, etc. George Alter has now shown that
uniform and continuous absorbing galactic lay
is possible to determine the absorbing condition
the observed relation between colour index
absolute magnitude (*Mon. Not. Roy. Astro. Soc.*,
2; 1941). An investigation is made on the li
for the photovisual, photographic and selec
absorption coefficients, and the two assumption
this investigation are based on experience. I
additional theoretical assumption is made, the s
tive law, derived by Stebbins, Huffer and Whit
these limits are restricted further. Some sugges
are made for the determination of the actual c
cients. One of these is that the absorption c
tions in the 'galactic windows' might be car
investigated, the influence of absorbing clouds
thus avoided so far as possible.

Stellar Lithium

RECENT theories of energy generation in the c
stars (see, for example, NATURE, **144**, 575;
postulate the interaction of protons and the n
of light elements such as lithium in stellar inte
Until now the only extra-terrestrial evidence for
existence of lithium atoms has been the faint o
rence in the solar spectrum of the resonance d
of neutral lithium at 6708 A., the lithium ana
of the sodium *D* lines. Now, however, Dr.
McKellar reports (*Observatory*, **64**, 4; 1941) that
doublet occurs strongly in the spectrum of the *N*-
giant variable star *WZ* Cassiopeiæ, being seco
intensity only to the *D* lines themselves. A puz
feature of the discovery is that this star is a
among the ten or more *R*- and *N*-type stars e
ined by McKellar in showing the lithium lines;
in other respects, such as absolute magnitude
radius, it does not appear abnormal. Astrophysi
are always loth to attribute abnormal strength
spectral line to abnormal abundance of the em
element, but the facts here do seem to sugges
lithium is unusually abundant in the atmosphe
this particular star.

THE ROCKEFELLER FOUNDATION

N his review of the work of the Rockefeller Foundation in 1940, the president, Dr. Raymond B. dick, refers to the limitation of the Foundation's k through the extension of the War. Projects in way, Belgium, Holland, Denmark, France and mania could no longer be assisted, but in spite of s interference, 23 per cent of the Rockefeller undation appropriations of 9,854,497 dollars during year were spent abroad in forty-four countries Europe, Asia, Africa and the Americas in six ajor fields—public health, natural sciences, social iences, medical sciences, humanities and rural construction in China. Early in July 1940, a ealth Commission to Europe was organized, and r. Willow A. Sawyer, director of the International ealth Division, made two extended trips to rope, visiting France, England, Spain and Portugal. bacteriologist-epidemiologist has been sent to ngland at the request of the Ministry of Health to udy the influenza problem, and plans are under ay to send one or more experts in nutrition and a ecialist in typhus fever to Spain, and a bacteriolog--epidemiologist to France. Restrictions of com-unications between Europe and America have verely limited the development of this programme, t Dr. Fosdick refers to work in the Foundation's boratories under Dr. F. L. Horsfall on the velopment of a satisfactory anti-influenza vaccine. is hoped that by the winter of 1941–42 an experi-ntal vaccine will be available which can be applied at least three different types of the influenza isease.

The report gives further details of the progress of e campaign against the *Anopheles gambiæ* mosquito Brazil, which has now restricted the activities of this fly to the low Jaguaribe valley, and it appears possible to contemplate its eradication from Brazil. Investigations on yellow fever in Colombia suggest that it is primarily a disease of jungle animals, transmission from man to man by the *Ædes ægypti* mosquito being a secondary cycle depending on population conditions and mosquito breeding created by man himself. Transmission of jungle yellow fever appears to be by jungle mosquitoes from animal to animal, and there is no animal reservoir of virus in the usual sense. Vaccination of the population in contact with the infected forest area is the most important measure of control. The Foundation supplied 250,000 doses of its yellow fever vaccine to the Sudan at the request of the British Government to deal with a sharp outbreak of the fever in the Nubian mountains.

A new school of public health is being developed at the University of Michigan with a grant of 500,000 dollars from the Foundation and a similar sum from the W. K. Kellogg Foundation. Most of the appropriations in medical sciences in 1940 relate to teaching and research in psychiatry, neurology and psychology or preventive medicine. Reference is also made to the new giant cyclotron under construction at Berkeley, California, and its significance as an expression of man's hunger for knowledge and unassuageable search for truth. Here, as in his references to science and the moral order, to the challenge to the social sciences, to refugee scientific workers and the conditions in European universities, Dr. Fosdick once more reveals his appreciation of the way in which freedom and scholarship, science and learning, are bound up with the success of the cause of democracy.

SEASONAL RHYTHM OF A FLY

By Dr. Ll. Lloyd,

University of Leeds

PROLONGED and uniform trapping of the flies emerging from the bacteria beds of sewage works t Leeds has demonstrated a type of seasonal rhythm t is probably common in rapidly breeding insects. *aniotoma minima* Mg. (Chironomidæ) prevails hroughout the year, and during eight years of ollecting has appeared in almost every week. It is a minimum about April, increases to a maximum August or September and then declines rather owly. On the basis of the monthly totals the umerical change is steady and the curve of incidence moulded partly by the progress-temperature law d partly by the pressure of competing species[1]. If e weekly catches from the traps are considered, it seen that whether the general seasonal abundance low or high there are peak periods of emergence, hallow and obtuse in winter, sharp and abrupt in mmer, abrupt and with a tendency to be flat-pped in autumn. There is evidently a periodicity these peaks and the interval is less than that required for a complete life-cycle. An analysis of the figures shows that successions of generations are running, always two and sometimes three.

One such succession, *A*, has been traced through seventeen generations from November 13–17, 1937, to October 14–21, 1940, when it reaches a flat-topped peak which splits. Another succession, *B*, has been traced through nine generations from October 23, 1937, to the summer of 1939, when it loses itself in *A*. A third, *C*, has been traced from December 17, 1938, when it has its origin in *B*, through eight generations to November 6, 1940. *A*, *B* and *C* run distinctly and parallel through almost one year. A portion of the record where *A* and *C* are running is shown in the accompanying table.

The generations have been traced by means of the daily average bed temperature and the thermal constants, the theoretical thresholds and required accumulations of day-degrees (*F*.) for the four phases of the cycle being as follows: maturation of the

ALTERNATION OF A SUCCESSION OF TWO GENERATIONS, *A* AND *C* OF A FLY (*Spaniotoma minima*) AND A SIMILAR SERIES *a* AND *b* OBTAINED BY THEORY FROM AN ORIGINALLY UNIFORM POPULATION. TRAPPING NUMBERS ARE IN HUNDREDS.

female, 32/113·5° ; incubation of the egg, 39·5/68·5° ; growth of the larva, 38·5/689·5° ; pupation, 42/66·5°[2]. The longest cycle observed is 159 days, the theory demanding 146 days ; the shortest is 38 days, theory demanding 32 days. Tracing from peak to peak, the average error in 31 calculations is about 7 per cent, 26 being longer than theory demands while 5 are shorter. Of the former 18 are 1–7 days beyond expectation, and these are substantially accurate since the collections of flies cover the emergence of one week. The behaviour of the insect thus covers expectation very well, and by means of a theoretical case it is possible to show the mechanism that produces the successions.

A uniform population of one unit a day has been imagined from August 7 to September 21, 1937, and it is supposed that their environment has the atmospheric shade temperature of the locality in order to get a sharper contrast and a quicker result than the equable bed temperatures would afford. Offspring from August 7 are due on September 22, so a complete generation has been covered. At first of course the units tend to scatter and regather as spring comes on and in doing so they tend to cluster until by July 1938 a group of six units has clustered for emergence on one day. By July 1939 a second group of six units has formed separated from the first by an interval of 14 days. Three other groups of four units each have also formed, the rest remaining scattered or in twos. By 1940 the population, assessed weekly, has assumed a form strikingly like that of the fly in Nature. Part of the record is shown in the table with the generation intervals marked *a* . . . *a* and *b* . . . *b*. It seems likely tha if the calculation were carried through a sufficie number of years the original forty-six units would aggregate into two or three isolated groups. Suc an abrupt result could not obtain in Nature partly because a family spreads itself over several days in emergence and partly because of the reversal process

Moderately abrupt temperature changes extendin over a few days near the beginning or near the end o the cycle are responsible for the phenomenon. The spring rises especially tend to cluster the offspring whose parents were widely separated in time. Once a distinctive peak is formed it persists until it happens to be involved in such a change. Sudden temperature falls in autumn especially tend to split the flat-topped peaks mentioned above. In the table, for example, the flies of August 14 just avoid a temperature fall which envelops the second half of the peak on August 21. The result is that a saddle-backed peak develops on October 2–9–16. The split persists in the present year.

It seems imperative that a rapidly breeding insect the speed of development of which is governed solely by the progress-temperature law must behave in this way. *Psychoda alternata*, which also breeds in bacteria beds certainly does so, and its case is being examined in detail. Many insects have their seasonal incidence regulated by the 'diapause', a coma-like state instituted at some suitable point in the life-cycle by ancestral experience of the weather of the average year and calculated to terminate at a time when conditions should be favourable. Sometimes the diapause persists until a second or third favourable season should be due. Thus the likelihood of extermination through an unfavourable season is reduced. The commoner sewage flies show no such phase, but the mechanism here demonstrated and wholely dependent on physico-chemical regulation would seem to serve the same end. *S. minima* requires fairly mild calm weather for the mating dance. A single flight might be unable to achieve mating through encountering a cold stormy period. Repetition of the flight with an interval makes disaster through these means much less likely.

ELIMINATION REACTIONS IN ORGANIC CHEMISTRY

MECHANISM

IN classical organic chemistry, two empirical rules, each of limited application, summarize the regularities which have been observed to govern the formation of olefins from alkyl compounds. Hofmann's rule (an extended form of the rule originally given by Hofmann), applying to primary alkyl groups in ammonium or sulphonium hydroxides, refers to the preferential production of the least alkylated of the possible alkyl ethylenes. Saytzeff's rule, relating to secondary and tertiary alkyl groups in alkyl halides, expresses the predominating formation of the most alkylated of the possible alkyl ethylenes. Having regard to the close analogy of the elimination reactions of 'onium salts and halides, the contrary tendencies of these two rules is striking. The need for an explanation was strongly emphasized when in 1927 Hofmann's rule was rationalized as a manifestation of the inductive effect[1], that is, of a very general type of molecular polarization, which must from its nature oppose the operation of Saytzeff's rule. We have since been much concerned with the problem of reconciling and rationalizing the two rules, but the work has not been published, because, until comparatively recently, the solution was not established. An outline is now given as it may still be some time before detailed publication is possible.

We refer first to methods. The data hitherto available for summarization in the two rules are mainly 'orientational' ; that is, they relate to the proportions in which alternative products are formed; such proportions represent at best only the ratios of the rates of simultaneous decompositions. Thus the Hofmann rule refers to the formation of olefins from alternative primary alkyl groups in the 'onium structure, while the Saytzeff rule relates to the alternative isomeric olefins derived from the solitary branched-chain alkyl group of a secondary or tertiary halide. By examining the kinetics of the reactions, we have provided, besides these rate ratios, the individual rate constants, which permit more extensive and much more significant comparison. Thus we are able to include primary alkyl halides, for which orientational data are impossible.

The most important point, however, relates to mechanism. Primary alkyl 'onium salts and halides yield olefins mainly by the bimolecular mechanism *E*2 (attack of a base on an alkyl proton), but the corresponding secondary or tertiary alkyl compounds react partly or wholly by the unimolecular mechanism *E*1 (prior formation of a carbonium ion), and in many cases either mechanism may predominate depending on the conditions. Kinetic control is therefore essential to ensure that only reactions of identical mechanism are compared; and that they are compared on the most appropriate lines. We compare the specific rates for mechanism *E*2, and the ratios in which the carbonium ion is partitioned between elimination and substitution for mechanism *E*1. The comparative simplicity of the results is essentially dependent on the use of the kinetic method.

The data reveal two distinct and characteristic sets of constitutional influences, of which the Hofmann and Saytzeff rules respectively are partial statements: we retain these names for the extended groups of phenomena. Their fields of control are as follows. 'Onium salt reactions proceeding by mechanism *E*2 display 'Hofmann influences'; those going by mechanism *E*1 show 'Saytzeff influences'. Halide reactions by both mechanisms *E*2 and *E*1 are governed by Saytzeff influences. Within the investigated range, these statements remain true no matter whether the alkyl groups are primary, secondary, or tertiary, provided that they are saturated. The introduction of suitably placed unsaturation increases the field of application of Saytzeff influences.

When Hofmann influences are present, the successive variation $R = H, Me, Et$, etc. in $R.\overset{\beta}{C}H_2.\overset{\alpha}{C}H_2.X$ leads to an initial sharp decrease, followed by successively smaller decreases, in the bimolecular rate of elimination. These rate relations, as well as those applying to more complicated alkyl groups, are consistent with the belief that the responsible internal mechanism is the inductive effect: electron displacement in the bond RC_β decreases the induced positive charge on C_β, thereby inhibiting the loss of the β-proton.

When Saytzeff influences are in control, the variation $R = H, Me, Et$, in $R.CH_2.CH_2.X$ leads to an initial sharp increase followed, not by any further increase, but by a decrease of smaller magnitude than the original increase in the bimolecular rate, or unimolecular partition ratio for elimination. These relations, and those observed with more complex groups, are consistent with the theory that the responsible mechanism involves resonance due to the quasi-conjugation[2] of the HC_γ-electrons with the electrons transferred in elimination from the dissolving HC_β-bond to the forming $C_\beta C_\alpha$-double-bond: the energy of quasi-conjugation facilitates this electron transference and thus promotes the proton loss. The greater the number of HC_γ-bonds, the larger will be this effect; and, of course, a much more powerful effect of the same kind arises when, in place of quasi-conjugation, full conjugation is produced by the provision of γ-unsaturation as in the β-phenylethyl group.

Thus for elimination reactions we envisage a situation very similar to that already elucidated for aromatic substitution: independent electrostatic and resonance effects co-exist; and being separately energized they may even work in opposition. When they do, the question of their relative importance assumes special interest.

We expect the importance of quasi-conjugation to increase with the electron defect developed at C_α in the transition state of olefin formation; for the effect depends on the possibility of the electromeric displacement,  in the transition state. We find that in fact Saytzeff influences are subsidiary in the *E*2 reactions of 'onium salts, dominating in the *E*2 reactions of halides, and more strongly dominating in the *E*1 reactions of either 'onium salts or halides; in short, these influences increase when the precursor of the olefin successively contains the groups $C_\alpha—\overset{+}{X}$, C_α—Hal, $\overset{+}{C}_\alpha$. The electron defect at C_α is clearly greatest in the last example; and we may reasonably expect it to be greater in the second than in the first, because the stretching of the C—Hal bond is assisted by solvation due to the charges created by a partial electron transfer from C to Hal, while a corresponding energetic factor is lacking in the activation of the bond $C—\overset{+}{X}$.

We may add that other reactions leading to olefins, for example, those of alcohols and ethers, fall consistently within the theoretical scheme outlined.

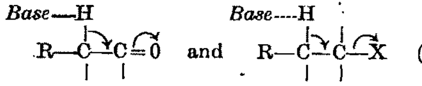
TAUTOMERISM AND ELIMINATION

About twenty years ago the outlook on theoretical problems connected with tautomerism was considerably enlarged by the proposal to regard tautomeric changes, for certain purposes, as internal analogues of additive reactions[1]; thus the study of ring-chain tautomerism developed as a direct consequence of this point of view. It is curious that the complementary and equally valid idea of regarding tautomeric change as an internal form of elimination seems never to have been explored. Consideration shows that it leads to many striking analogies and correlations. This note is confined to a single illustration chosen because it happens to be simply explicable in terms of the preceding communication,

The comparison is between



(X = $\overset{+}{N}$, $\overset{+}{S}$, Hal),

the former diagram representing the rate-determining step of a base-catalysed enolization, the latter an ordinary elimination by mechanism $E2$. The difference is that the combination CO does not break up completely while CX does. The question to be considered is whether the effect of alkyl groups R on the rate of enolization of a ketone (now regarded as an elimination reaction) will be of the 'Hofmann type' or the 'Saytzeff type'. Relatively to CX, the stretching of CO in the transition state must be small, and accordingly the electron defect on the carbon atom and the dependent quasi-conjugation, developed in the course of reaction, may be assumed to be comparatively unimportant. It is therefore not surprising that the effect of alkyl groups on rate is found to be of the Hofmann type. This may be illustrated by Evans and Gordon's results[2] for the rate of bromination (kinetically equivalent to enolization) of phenyl alkyl ketones, CHRR′.CO.Ph in the presence of acetate ions as basic catalyst:

R,R′	H,H	Me,H	Et,H	Pr$^{\beta}$,H.	Me,Me
$10^3 k_{45°}$	52·0	7·99	6·24	3·05	1·55

Examples of 'Hofmann influences' are also to be found in the effect of alkyl substitution on rate of interconversion in the case of 'three-carbon' prototropy.

A contrast to these effects on reaction rate is afforded by evidence that the effects of alkyl substituents on prototropic equilibria are essentially dependent on the same internal mechanism as underlies what have here been called Saytzeff influences on rate (preceding note). The ground states alone are important for equilibria, with the result that, in the tautomerism of olefinic acids, for example, the introduction of a γ-alkyl group shifts the equilibrium in favour of the βγ-form. Consistently a methyl group is more effective in this respect than higher alkyl groups. This effect may be illustrated by the results of Kon and Linstead[3] for the base-catalysed equilibria of the anions of a series of acrylic acids, $RR'C=CH.CO_2H$:

RR′.	Me_2	Et_2	Pr_2^{α}	*iso*-Bu_2
γ-substituent	.H	$.CH_3$	$.CH_2CH_3$	$.CH\begin{smallmatrix}CH_3\\ CH_3\end{smallmatrix}$
αβ-form (%)	100	5	33	49

The importance of quasi-conjugation for equilibria may also be illustrated with reference to anionotropic change. The predominating formation of crotyl and cinnamyl halides in the equilibration of the butenyl and phenylpropenyl halides are familiar examples.
